The WEIGHT statement and the `_WEIGHT_` variable operate on all the residuals in a system of equations. If a subset of the equations needs to be weighted, the residuals for each equation can be modified through the RESID. variable for each equation. The following example demonstrates the use of the RESID. variable to make a homoscedastic error term:

```
proc model data=test;
  parms b1 0.1 b2 0.9;
  y = 250 * ( exp( -b1 * t ) - exp( -b2 * t ) );
  resid.y = resid.y * sqrt(t);
  fit y;
run;
```

These statements produce estimates of the parameters and standard errors that are identical to the weighted OLS estimates. The reassignment of the RESID.Y variable must be done after Y is assigned; otherwise it would have no effect. Also, note that the residual (RESID.Y) is multiplied by \sqrt{t} . Here the multiplier is acting on the residual before it is squared.

GMM Estimation

If the form of the heteroscedasticity is unknown, generalized method of moments estimation (GMM) can be used. The following PROC MODEL statements use GMM to estimate the example model used in the preceding section:

```
proc model data=test;
  parms b1 0.1 b2 0.9;
  y = 250 * ( exp( -b1 * t ) - exp( -b2 * t ) );
  fit y / gmm;
  instruments b1 b2;
run;
```

GMM is an instrumental method, so instrument variables must be provided.

GMM estimation generates estimates for the parameters shown in Figure 18.42.

Figure 18.42 GMM Estimation for Heteroscedasticity

The MODEL Procedure				
Nonlinear GMM Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
b1	0.200487	0.000800	250.69	<.0001
b2	0.822148	0.0148	55.39	<.0001

Heteroscedasticity-Consistent Covariance Matrix Estimation

Homoscedasticity is required for ordinary least squares regression estimates to be efficient. A nonconstant error variance, heteroscedasticity, causes the OLS estimates to be inefficient, and the usual OLS covariance matrix, $\hat{\Sigma}$, is generally invalid:

$$\hat{\Sigma} = \sigma^2(\mathbf{X}'\mathbf{X})^{-1}$$

When the variance of the errors of a classical linear model

$$Y = \mathbf{X}\beta + \epsilon$$

is not constant across observations (heteroscedastic), so that $\sigma_i^2 \neq \sigma_j^2$ for some $j > 1$, the OLS estimator

$$\hat{\beta}_{OLS} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'Y$$

is unbiased but it is inefficient. Models that take into account the changing variance can make more efficient use of the data. When the variances, σ_t^2 , are known, generalized least squares (GLS) can be used and the estimator

$$\hat{\beta}_{GLS} = (\mathbf{X}'\mathbf{\Omega}\mathbf{X})^{-1}\mathbf{X}'\mathbf{\Omega}^{-1}Y$$

where

$$\mathbf{\Omega} = \begin{bmatrix} \sigma_1^2 & 0 & 0 & 0 \\ 0 & \sigma_2^2 & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \sigma_T^2 \end{bmatrix}$$

is unbiased and efficient. However, GLS is unavailable when the variances, σ_t^2 , are unknown.

To solve this problem White (1980) proposed a heteroscedastic consistent-covariance matrix estimator (HCCME)

$$\hat{\Sigma} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\hat{\mathbf{\Omega}}\mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}$$

that is consistent as well as unbiased, where

$$\hat{\mathbf{\Omega}}_0 = \begin{bmatrix} \epsilon_1^2 & 0 & 0 & 0 \\ 0 & \epsilon_2^2 & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \epsilon_T^2 \end{bmatrix}$$

and $\epsilon_t = Y_t - \mathbf{X}_t\hat{\beta}_{OLS}$.

This estimator is considered somewhat unreliable in finite samples. Therefore, Davidson and MacKinnon (1993) propose three different modifications to estimating $\hat{\mathbf{\Omega}}$. The first solution is

to simply multiply ϵ_t^2 by $\frac{n}{n-df}$, where n is the number of observations and df is the number of explanatory variables, so that

$$\hat{\Omega}_1 = \begin{bmatrix} \frac{n}{n-df} \epsilon_1^2 & 0 & 0 & 0 \\ 0 & \frac{n}{n-df} \epsilon_2^2 & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \frac{n}{n-df} \epsilon_n^2 \end{bmatrix}$$

The second solution is to define

$$\hat{\Omega}_2 = \begin{bmatrix} \frac{\epsilon_1^2}{1-\hat{h}_1} & 0 & 0 & 0 \\ 0 & \frac{\epsilon_2^2}{1-\hat{h}_2} & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \frac{\epsilon_n^2}{1-\hat{h}_n} \end{bmatrix}$$

where $\hat{h}_t = \mathbf{X}_t(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'_t$.

The third solution, called the “jackknife,” is to define

$$\hat{\Omega}_3 = \begin{bmatrix} \frac{\epsilon_1^2}{(1-\hat{h}_1)^2} & 0 & 0 & 0 \\ 0 & \frac{\epsilon_2^2}{(1-\hat{h}_2)^2} & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \frac{\epsilon_n^2}{(1-\hat{h}_n)^2} \end{bmatrix}$$

MacKinnon and White (1985) investigated these three modified HCCMEs, including the original HCCME, based on finite-sample performance of pseudo- t statistics. The original HCCME performed the worst. The first modification performed better. The second modification performed even better than the first, and the third modification performed the best. They concluded that the original HCCME should never be used in finite sample estimation, and that the second and third modifications should be used over the first modification if the diagonals of $\hat{\Omega}$ are available.

Seemingly Unrelated Regression HCCME

Extending the discussion to systems of g equations, the HCCME for SUR estimation is

$$(\tilde{\mathbf{X}}'\tilde{\mathbf{X}})^{-1}\tilde{\mathbf{X}}'\hat{\Omega}\tilde{\mathbf{X}}(\tilde{\mathbf{X}}'\tilde{\mathbf{X}})^{-1}$$

where $\tilde{\mathbf{X}}$ is a $ng \times k$ matrix with the first g rows representing the first observation, the next g rows representing the second observation, and so on. $\hat{\Omega}$ is now a $ng \times ng$ block diagonal matrix with typical block $g \times g$

$$\hat{\Omega}_i = \begin{bmatrix} \psi_{1,i} & \psi_{1,i} & \psi_{1,i} & \psi_{2,i} & \cdots & \psi_{1,i} & \psi_{g,i} \\ \psi_{2,i} & \psi_{1,i} & \psi_{2,i} & \psi_{2,i} & \cdots & \psi_{2,i} & \psi_{g,i} \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ \psi_{g,i} & \psi_{1,i} & \psi_{g,i} & \psi_{2,i} & \cdots & \psi_{g,i} & \psi_{g,i} \end{bmatrix}$$

where

$$\psi_{j,i} = \epsilon_{j,i} \quad HC_0$$

or

$$\psi_{j,i} = \sqrt{\frac{n}{n-df}} \epsilon_{j,i} \quad HC_1$$

or

$$\psi_{j,i} = \epsilon_{j,i} / \sqrt{1 - \hat{h}_i} \quad HC_2$$

or

$$\psi_{j,i} = \epsilon_{j,i} / (1 - \hat{h}_i) \quad HC_3$$

Two- and Three-Stage Least Squares HCCME

For two- and three-stage least squares, the HCCME for a g equation system is

$$\text{Cov} F(\hat{\Omega}) \text{Cov}$$

where

$$\text{Cov} = \left(\frac{1}{n} \mathbf{X}' (\mathbf{I} \otimes \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1} \mathbf{Z}') \mathbf{X} \right)^{-1}$$

is the normal covariance matrix without the \mathbf{S} matrix and

$$F(\Omega) = \frac{1}{n} \sum_i^g \sum_j^g \mathbf{X}'_i \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1} \mathbf{Z}' \hat{\Omega}_{ij} \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1} \mathbf{Z}' \mathbf{X}_j$$

where \mathbf{X}_j is a $n \times p$ matrix with the j th equations regressors in the appropriate columns and zeros everywhere else.

$$\hat{\Omega}_{ij} = \begin{bmatrix} \psi_{i,1} \psi_{j,1} & 0 & 0 & 0 \\ 0 & \psi_{i,2} \psi_{j,2} & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \psi_{i,n} \psi_{j,n} \end{bmatrix}$$

For 2SLS $\hat{\Omega}_{ij} = 0$ when $i \neq j$. The ϵ_t used in $\hat{\Omega}$ is computed by using the parameter estimates obtained from the instrumental variables estimation.

The leverage value for the i th equation used in the HCCME=2 and HCCME=3 methods is computed as conditional on the first stage as

$$h_{ti} = \mathbf{Z}_t(\mathbf{Z}'\mathbf{Z})^{-1} \mathbf{X}_i (\mathbf{X}' (\mathbf{I} \otimes \mathbf{Z}(\mathbf{Z}' * \mathbf{Z})^{-1} \mathbf{Z}') \mathbf{X})^{-1} \mathbf{X}'_i \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1} \mathbf{Z}'_t$$

for 2SLS and

$$h_{ti} = \mathbf{Z}_t(\mathbf{Z}'\mathbf{Z})^{-1} \mathbf{X}_i (\mathbf{X}' (\mathbf{S}^{-1} \otimes \mathbf{Z}(\mathbf{Z}' * \mathbf{Z})^{-1} \mathbf{Z}') \mathbf{X})^{-1} \mathbf{X}'_i \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1} \mathbf{Z}'_t / S_{ii}$$

for 3SLS.

Testing for Autocorrelation

The GODFREY= option in the FIT statement produces the Godfrey Lagrange multiplier test for serially correlated residuals for each equation (Godfrey 1978a and 1978b). n is the maximum autoregressive order, and specifies that Godfrey's tests be computed for lags 1 through n . The default number of lags is four.

The tests are performed separately for each equation estimated by the FIT statement. When a nonlinear model is estimated, the test is computed by using a linearized model.

The following is an example of the output produced by the GODFREY=3 option:

Figure 18.43 Autocorrelation Test Output

Godfrey Test Output			
The MODEL Procedure			
Godfrey's Serial Correlation Test			
Equation	Alternative	LM	Pr > LM
y	1	6.63	0.0100
	2	6.89	0.0319
	3	6.96	0.0732

The three variations of the test reported by the GODFREY=3 option are designed to have power against different alternative hypothesis. Thus, if the residuals in fact have only first-order autocorrelation, the lag 1 test has the most power for rejecting the null hypothesis of uncorrelated residuals. If the residuals have second- but not higher-order autocorrelation, the lag 2 test might be more likely to reject; the same is true for third-order autocorrelation and the lag 3 test.

The null hypothesis of Godfrey's tests is that the equation residuals are white noise. However, if the equation includes autoregressive error model of order p ($AR(p)$), then the lag i test, when considered in terms of the structural error, is for the null hypothesis that the structural errors are from an $AR(p)$ process versus the alternative hypothesis that the errors are from an $AR(p + i)$ process.

The alternative $ARMA(p, i)$ process is locally equivalent to the alternative $AR(p + i)$ process with respect to the null model $AR(p)$. Thus, the GODFREY= option results are also a test of $AR(p)$ errors against the alternative hypothesis of $ARMA(p, i)$ errors. See Godfrey (1978a and 1978b) for more detailed information.

Transformation of Error Terms

In PROC MODEL you can control the form of the error term. By default, the error term is assumed to be additive. This section demonstrates how to specify nonadditive error terms and discusses the effects of these transformations.

Models with Nonadditive Errors

The estimation methods used by PROC MODEL assume that the error terms of the equations are independently and identically distributed with zero means and finite variances. Furthermore, the methods assume that the *RESID.name* equation variable for normalized form equations or the *EQ.name* equation variable for general form equations contains an estimate of the error term of the true stochastic model whose parameters are being estimated. Details on *RESID.name* and *EQ.name* equation variables are in the section “Equation Translations” on page 1204.

To illustrate these points, consider the common loglinear model

$$y = \alpha x^\beta \quad (1)$$

$$\ln y = a + b \ln(x) \quad (2)$$

where $a = \log(\alpha)$ and $b = \beta$. Equation (2) is called the *log form* of the equation in contrast to equation (1), which is called the *level form* of the equation. Using the SYSLIN procedure, you can estimate equation (2) by specifying

```
proc syslin data=in;
  model logy=logx;
run;
```

where LOGY and LOGX are the logs of Y and X computed in a preceding DATA step. The resulting values for INTERCEPT and LOGX correspond to a and b in equation (2).

Using the MODEL procedure, you can try to estimate the parameters in the level form (and avoid the DATA step) by specifying

```
proc model data=in;
  parms alpha beta;
  y = alpha * x ** beta;
  fit y;
run;
```

where ALPHA and BETA are the parameters in equation (1).

Unfortunately, at least one of the preceding is wrong; an ambiguity results because equations (1) and (2) contain no explicit error term. The SYSLIN and MODEL procedures both deal with additive errors; the residual used (the estimate of the error term in the equation) is the difference between the predicted and actual values (of LOGY for PROC SYSLIN and of Y for PROC MODEL in this example). If you perform the regressions discussed previously, PROC SYSLIN estimates equation (3) while PROC MODEL estimates equation (4).

$$\ln y = a + b \ln(x) + \epsilon \quad (3)$$

$$y = \alpha x^\beta + \xi \quad (4)$$

These are different statistical models. Equation (3) is the log form of equation (5)

$$y = \alpha x^\beta \mu \quad (5) \text{ where } \mu = e^\epsilon.$$
 Equation (4), on the other hand, cannot be linearized because the error term ξ (different from μ) is additive in the level form.

You must decide whether your model is equation (4) or (5). If the model is equation (4), you should use PROC MODEL. If you linearize equation (1) without considering the error term and apply SYSLIN to MODEL LOGY=LOGX, the results will be wrong. On the other hand, if your model is equation (5) (in practice it usually is), and you want to use PROC MODEL to estimate the parameters in the *level* form, you must do something to account for the multiplicative error.

PROC MODEL estimates parameters by minimizing an objective function. The objective function is computed using either the RESID.-prefixed equation variable or the EQ.-prefixed equation variable. You must make sure that these prefixed equation variables are assigned an appropriate error term. If the model has additive errors that satisfy the assumptions, nothing needs to be done. In the case of equation (5), the error is nonadditive and the equation is in normalized form, so you must alter the value of RESID.Y.

The following assigns a valid estimate of μ to RESID.Y:

```
y = alpha * x ** beta;
resid.y = actual.y / pred.y;
```

However, $\mu = e^\epsilon$, and therefore μ , cannot have a mean of zero, and you cannot consistently estimate α and β by minimizing the sum of squares of an estimate of μ . Instead, you use $\epsilon = \ln\mu$.

```
proc model data=in;
  parms alpha beta;
  y = alpha * x ** beta;
  resid.y = log( actual.y / pred.y );
  fit y;
run;
```

If the model was expressed in general form, this transformation becomes

```
proc model data=in;
  parms alpha beta;
  EQ.trans = log( y / (alpha * x ** beta) );
  fit trans;
run;
```

Both examples produce estimates of α and β of the level form that match the estimates of a and b of the log form. That is, ALPHA=exp(INTERCEPT) and BETA=LOGX, where INTERCEPT and LOGX are the PROC SYSLIN parameter estimates from the MODEL LOGY=LOGX. The standard error reported for ALPHA is different from that for the INTERCEPT in the log form.

The preceding example is not intended to suggest that loglinear models should be estimated in level form but, rather, to make the following points:

- Nonlinear transformations of equations involve the error term of the equation, and this should be taken into account when transforming models.
- The RESID.-prefixed and the EQ.-prefixed equation variables for models estimated by the MODEL procedure must represent additive errors with zero means.
- You can use assignments to RESID.-prefixed and EQ.-prefixed equation variables to transform error terms.
- Some models do not have additive errors or zero means, and many such models can be estimated using the MODEL procedure. The preceding approach applies not only to multiplicative models but to any model that can be manipulated to isolate the error term.

Predicted Values of Transformed Models

Nonadditive or transformed errors affect the distribution of the predicted values, as well as the estimates. For the preceding loglinear example, the MODEL procedure produces consistent parameter estimates. However, the predicted values for Y computed by PROC MODEL are not unbiased estimates of the expected values of Y, although they do estimate the conditional median Y values.

In general, the predicted values produced for a model with nonadditive errors are not unbiased estimates of the conditional means of the endogenous value. If the model can be transformed to a model with additive errors by using a *monotonic* transformation, the predicted values estimate the conditional medians of the endogenous variable.

For transformed models in which the biasing factor is known, you can use programming statements to correct for the bias in the predicted values as estimates of the endogenous means. In the preceding log-linear case, the predicted values are biased by the factor $\exp(\sigma^2/2)$. You can produce approximately unbiased predicted values in this case by writing the model as

```
proc model data=in;
  parms alpha beta;
  y=alpha * x ** beta;
  resid.y = log( actual.y / pred.y );
  fit y;
run;
```

See Miller (1984) for a discussion of bias factors for predicted values of transformed models.

Note that models with transformed errors are not appropriate for Monte Carlo simulation that uses the SDATA= option. PROC MODEL computes the OUTS= matrix from the transformed RESID.-prefixed equation variables, while it uses the SDATA= matrix to generate multivariate normal errors, which are added to the predicted values. This method of computing errors is inconsistent when the equation variables have been transformed.

Error Covariance Structure Specification

One of the key assumptions of regression is that the variance of the errors is constant across observations. Correcting for heteroscedasticity improves the efficiency of the estimates.

Consider the following general form for models:

$$\begin{aligned} \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) &= \boldsymbol{\varepsilon}_t \\ \boldsymbol{\varepsilon}_t &= H_t * \boldsymbol{\epsilon}_t \\ H_t &= \begin{bmatrix} \sqrt{h_{t,1}} & 0 & \dots & 0 \\ 0 & \sqrt{h_{t,2}} & \dots & 0 \\ & & \ddots & \\ 0 & 0 & \dots & \sqrt{h_{t,g}} \end{bmatrix} \\ \mathbf{h}_t &= \mathbf{g}(\mathbf{y}_t, \mathbf{x}_t, \phi) \end{aligned}$$

where $\boldsymbol{\epsilon}_t \sim N(0, \Sigma)$.

For models that are homoscedastic,

$$h_t = 1$$

If you have a model that is heteroscedastic with known form, you can improve the efficiency of the estimates by performing a weighted regression. The weight variable, using this notation, would be $1/\sqrt{h_t}$.

If the errors for a model are heteroscedastic and the functional form of the variance is known, the model for the variance can be estimated along with the regression function.

To specify a functional form for the variance, assign the function to an `H.var` variable where `var` is the equation variable. For example, if you want to estimate the scale parameter for the variance of a simple regression model

$$y = a * x + b$$

you can specify

```
proc model data=s;
  y = a * x + b;
  h.y = sigma**2;
fit y;
```

Consider the same model with the following functional form for the variance:

$$h_t = \sigma^2 * x^{2*\alpha}$$

This would be written as

```

proc model data=s;
  y = a * x + b;
  h.y = sigma**2 * x**(2*alpha);
fit y;

```

There are three ways to model the variance in the MODEL procedure: feasible generalized least squares, generalized method of moments, and full information maximum likelihood.

Feasible GLS

A simple approach to estimating a variance function is to estimate the mean parameters θ by using some auxiliary method, such as OLS, and then use the residuals of that estimation to estimate the parameters ϕ of the variance function. This scheme is called *feasible GLS*. It is possible to use the residuals from an auxiliary method for the purpose of estimating ϕ because in many cases the residuals consistently estimate the error terms.

For all estimation methods except GMM and FIML, using the H.var syntax specifies that feasible GLS is used in the estimation. For feasible GLS, the mean function is estimated by the usual method. The variance function is then estimated using pseudo-likelihood (PL) function of the generated residuals. The objective function for the PL estimation is

$$p_n(\sigma, \theta) = \sum_{i=1}^n \left(\frac{(y_i - f(x_i, \hat{\beta}))^2}{\sigma^2 h(z_i, \theta)} + \log[\sigma^2 h(z_i, \theta)] \right)$$

Once the variance function has been estimated, the mean function is reestimated by using the variance function as weights. If an S-iterated method is selected, this process is repeated until convergence (iterated feasible GLS).

Note that feasible GLS does not yield consistent estimates when one of the following is true:

- The variance is unbounded.
- There is too much serial dependence in the errors (the dependence does not fade with time).
- There is a combination of serial dependence and lag dependent variables.

The first two cases are unusual, but the third is much more common. Whether iterated feasible GLS avoids consistency problems with the last case is an unanswered research question. For more information see Davidson and MacKinnon (1993, pp. 298–301) or Gallant (1987, pp. 124–125) and Amemiya (1985, pp. 202–203).

One limitation is that parameters cannot be shared between the mean equation and the variance equation. This implies that certain GARCH models, cross-equation restrictions of parameters, or testing of combinations of parameters in the mean and variance component are not allowed.

Generalized Method of Moments

In GMM, normally the first moment of the mean function is used in the objective function.

$$\begin{aligned} \mathbf{q}(y_t, \mathbf{x}_t, \theta) &= \epsilon_t \\ \mathbf{E}(\epsilon_t) &= 0 \end{aligned}$$

To add the second moment conditions to the estimation, add the equation

$$\mathbf{E}(\epsilon_t * \epsilon_t - h_t) = 0$$

to the model. For example, if you want to estimate σ for linear example above, you can write

```
proc model data=s;
  y = a * x + b;
  eq.two = resid.y**2 - sigma**2;
fit y two/ gmm;
instruments x;
run;
```

This is a popular way to estimate a continuous-time interest rate processes (see Chan et al. 1992). The H.var syntax automatically generates this system of equations.

To further take advantage of the information obtained about the variance, the moment equations can be modified to

$$\begin{aligned} \mathbf{E}(\epsilon_t / \sqrt{h_t}) &= 0 \\ \mathbf{E}(\epsilon_t * \epsilon_t - h_t) &= 0 \end{aligned}$$

For the above example, this can be written as

```
proc model data=s;
  y = a * x + b;
  eq.two = resid.y**2 - sigma**2;
  resid.y = resid.y / sigma;
fit y two/ gmm;
instruments x;
run;
```

Note that, if the error model is misspecified in this form of the GMM model, the parameter estimates might be inconsistent.

Full Information Maximum Likelihood

For FIML estimation of variance functions, the concentrated likelihood below is used as the objective function. That is, the mean function is coupled with the variance function and the system is solved simultaneously.

$$l_n(\phi) = \frac{ng}{2}(1 + \ln(2\pi)) - \sum_{t=1}^n \ln \left(\left| \frac{\partial \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)}{\partial \mathbf{y}_t} \right| \right) \\ + \frac{1}{2} \sum_{t=1}^n \sum_{i=1}^g (\ln(h_{t,i}) + \mathbf{q}_i(\mathbf{y}_t, \mathbf{x}_t, \theta)^2 / h_{t,i})$$

where g is the number of equations in the system.

The HESSIAN=GLS option is not available for FIML estimation that involves variance functions. The matrix used when HESSIAN=CROSS is specified is a crossproducts matrix that has been enhanced by the dual quasi-Newton approximation.

Examples

You can specify a GARCH(1,1) model as follows:

```
proc model data=modloc.usd_jpy;
    /* Mean model -----*/
    jpyret = intercept ;

    /* Variance model -----*/
    h.jpyret = arch0
    + arch1 * xlag( resid.jpyret ** 2, mse.jpyret )
    + garch1 * xlag(h.jpyret, mse.jpyret) ;

    bounds arch0 arch1 garch1 >= 0;

    fit jpyret / method=marquardt fiml;
run;
```

Note that the BOUNDS statement is used to ensure that the parameters are positive, a requirement for GARCH models.

EGARCH models are used because there are no restrictions on the parameters. You can specify a EGARCH(1,1) model as follows:

```
proc model data=sasuser.usd_dem ;
    /* Mean model -----*/
    demret = intercept ;
```

```

                /* Variance model -----*/
if ( _OBS_ =1 ) then
  h.demret = exp( earch0 + egarch1 * log(mse.demret) );
else
  h.demret = exp( earch0 + earch1 * zlag( g)
                + egarch1 * log(zlag(h.demret)));
  g = - theta * nresid.demret + abs( nresid.demret ) - sqrt(2/3.1415);

fit demret / method=marquardt fiml maxiter=100 converge=1.0e-6;
run;

```

Ordinary Differential Equations

Ordinary differential equations (ODEs) are also called *initial value problems* because a time zero value for each first-order differential equation is needed. The following is an example of a first-order system of ODEs:

$$\begin{aligned}
 y' &= -0.1y + 2.5z^2 \\
 z' &= -z \\
 y_0 &= 0 \\
 z_0 &= 1
 \end{aligned}$$

Note that you must provide an initial value for each ODE.

As a reminder, any n -order differential equation can be modeled as a system of first-order differential equations. For example, consider the differential equations

$$\begin{aligned}
 y'' &= by' + cy \\
 y_0 &= 0 \\
 y'_0 &= 1
 \end{aligned}$$

which can be written as the system of differential equations

$$\begin{aligned}
 y' &= z \\
 z' &= by' + cy \\
 y_0 &= 0 \\
 z_0 &= 1
 \end{aligned}$$

This differential system can be simulated as follows:

```

data t;
  time=0; output;
  time=1; output;
  time=2; output;

```

```
run;

proc model data=t ;
  dependent y 0 z 1;
  parm b -2 c -4;
  dert.y = z;
  dert.z = b * dert.y + c * y;

  solve y z / dynamic solveprint;
run;
```

The preceding statements produce the output shown in Figure 18.44. These statements produce additional output, which is not shown.

The differential variables are distinguished by the derivative with respect to time (DERT.) prefix. Once you define the DERT. variable, you can use it on the right-hand side of another equation. The differential equations must be expressed in normal form; implicit differential equations are not allowed, and other terms on the left-hand side are not allowed.

The TIME variable is the *implied with respect to* variable for all DERT. variables. The TIME variable is also the only variable that must be in the input data set.

You can provide initial values for the differential equations in the data set, in the declaration statement (as in the previous example), or in statements in the program. Using the previous example, you can specify the initial values as

```
proc model data=t ;
  dependent y z ;
  parm b -2 c -4;

  if ( time=0 ) then
    do;
      y=0;
      z=1;
    end;
  else
    do;
      dert.y = z;
      dert.z = b * dert.y + c * y;
    end;
  end;

  solve y z / dynamic solveprint;
run;
```

If you do not provide an initial value, 0 is used.

DYNAMIC and STATIC Simulation

Note that, in the previous example, the DYNAMIC option is specified in the SOLVE statement. The DYNAMIC and STATIC options work the same for differential equations as they do for dynamic systems. In the differential equation case, the DYNAMIC option makes the initial value needed at each observation the computed value from the previous iteration. For a static simulation, the data set must contain values for the integrated variables. For example, if DERT.Y and DERT.Z are the differential variables, you must include Y and Z in the input data set in order to do a static simulation of the model.

If the simulation is dynamic, the initial values for the differential equations are obtained from the data set, if they are available. If the variable is not in the data set, you can specify the initial value in a declaration statement. If you do not specify an initial value, the value of 0.0 is used.

A dynamic solution is obtained by solving one initial value problem for all the data. A graph of a simple dynamic simulation is shown in [Figure 18.45](#). If the time variable for the current observation is less than the time variable for the previous observation, the integration is restarted from this point. This allows for multiple samples in one data file.

Figure 18.45 Dynamic Solution

In a static solution, $n-1$ initial value problems are solved using the first $n-1$ data values as initial values. The equations are integrated using the i th data value as an initial value to the $i+1$ data value. Figure 18.46 displays a static simulation of noisy data from a simple differential equation. The static solution does not propagate errors in initial values as the dynamic solution does.

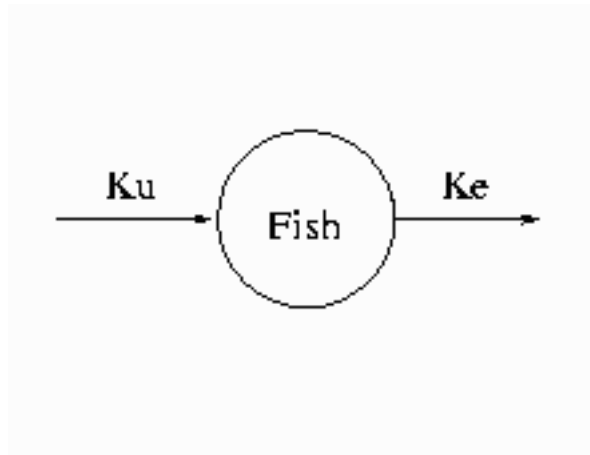

Figure 18.46 Static Solution

For estimation, the DYNAMIC and STATIC options in the FIT statement perform the same functions as they do in the SOLVE statement. Components of differential systems that have missing values or are not in the data set are simulated dynamically. For example, often in multiple compartment kinetic models, only one compartment is monitored. The differential equations that describe the unmonitored compartments are simulated dynamically.

For estimation, it is important to have accurate initial values for ODEs that are not in the data set. If an accurate initial value is not known, the initial value can be made an unknown parameter and estimated. This allows for errors in the initial values but increases the number of parameters to estimate by the number of equations.

Estimation of Differential Equations

Consider the kinetic model for the accumulation of mercury (Hg) in mosquito fish (Matis, Miller, and Allen 1991, p. 177). The model for this process is the one-compartment constant infusion model shown in Figure 18.47.

Figure 18.47 One-Compartment Constant Infusion Model

The differential equation that models this process is

$$\begin{aligned} \frac{dconc}{dt} &= k_u - k_e conc \\ conc_0 &= 0 \end{aligned}$$

The analytical solution to the model is

$$conc = (k_u/k_e)(1 - \exp(-k_e t))$$

The data for the model are

```
data fish;
  input day conc;
datalines;
0.0 0.0
1.0 0.15
2.0 0.2
3.0 0.26
4.0 0.32
6.0 0.33
;
```

To fit this model in differential form, use the following statements:

```
proc model data=fish;
  parm ku ke;

  dert.conc = ku - ke * conc;

  fit conc / time=day;
run;
```

The results from this estimation are shown in [Figure 18.48](#).

Figure 18.48 Static Estimation Results for Fish Model

The MODEL Procedure				
Nonlinear OLS Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
ku	0.180159	0.0312	5.78	0.0044
ke	0.524661	0.1181	4.44	0.0113

To perform a dynamic estimation of the differential equation, add the DYNAMIC option to the FIT statement.

```
proc model data=fish;
  parm ku .3 ke .3;

  dert.conc = ku - ke * conc;

  fit conc / time = day dynamic;
run;
```

The equation DERT.CONC is integrated from $conc(0) = 0$. The results from this estimation are shown in Figure 18.49.

Figure 18.49 Dynamic Estimation Results for Fish Model

The MODEL Procedure				
Nonlinear OLS Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
ku	0.167109	0.0170	9.84	0.0006
ke	0.469033	0.0731	6.42	0.0030

To perform a dynamic estimation of the differential equation and estimate the initial value, use the following statements:

```
proc model data=fish;
  parm ku .3 ke .3 conc0 0;

  dert.conc = ku - ke * conc;

  fit conc initial=(conc = conc0) / time = day dynamic;
run;
```

The INITIAL= option in the FIT statement is used to associate the initial value of a differential equation with a parameter. The results from this estimation are shown in Figure 18.50.

Figure 18.50 Dynamic Estimation with Initial Value for Fish Model

The MODEL Procedure				
Nonlinear OLS Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
ku	0.164408	0.0230	7.14	0.0057
ke	0.45949	0.0943	4.87	0.0165
conc0	0.003798	0.0174	0.22	0.8414

Finally, to estimate the fish model by using the analytical solution, use the following statements:

```
proc model data=fish;
  parm ku .3 ke .3;

  conc = (ku/ ke)*( 1 -exp(-ke * day));

  fit conc;
run;
```

The results from this estimation are shown in [Figure 18.51](#).

Figure 18.51 Analytical Estimation Results for Fish Model

The MODEL Procedure				
Nonlinear OLS Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
ku	0.167109	0.0170	9.84	0.0006
ke	0.469033	0.0731	6.42	0.0030

A comparison of the results among the four estimations reveals that the two dynamic estimations and the analytical estimation give nearly identical results (identical to the default precision). The two dynamic estimations are identical because the estimated initial value (0.00013071) is very close to the initial value used in the first dynamic estimation (0). Note also that the static model did not require an initial guess for the parameter values. Static estimation, in general, is more forgiving of bad initial values.

The form of the estimation that is preferred depends mostly on the model and data. If a very accurate initial value is known, then a dynamic estimation makes sense. If, additionally, the model can be written analytically, then the analytical estimation is computationally simpler. If only an approximate initial value is known and not modeled as an unknown parameter, the static estimation is less sensitive to errors in the initial value.

The form of the error in the model is also an important factor in choosing the form of the estimation. If the error term is additive and independent of previous error, then the dynamic mode is appropriate. If, on the other hand, the errors are cumulative, a static estimation is more appropriate. See the section “[Monte Carlo Simulation](#)” on page 1170 for an example.

Auxiliary Equations

Auxiliary equations can be used with differential equations. These are equations that need to be satisfied with the differential equations at each point between each data value. They are automatically added to the system, so you do not need to specify them in the SOLVE or FIT statement.

Consider the following example.

The Michaelis-Menten equations describe the kinetics of an enzyme-catalyzed reaction. The enzyme is E, and S is called the *substrate*. The enzyme first reacts with the substrate to form the enzyme-substrate complex ES, which then breaks down in a second step to form enzyme and products P.

The reaction rates are described by the following system of differential equations:

$$\begin{aligned}\frac{d[ES]}{dt} &= k_1([E] - [ES])[S] - k_2[ES] - k_3[ES] \\ \frac{d[S]}{dt} &= -k_1([E] - [ES])[S] + k_2[ES] \\ [E] &= [E]_{tot} - [ES]\end{aligned}$$

The first equation describes the rate of formation of ES from E + S. The rate of formation of ES from E + P is very small and can be ignored. The enzyme is in either the complexed or the uncomplexed form. So if the total ($[E]_{tot}$) concentration of enzyme and the amount bound to the substrate is known, $[E]$ can be obtained by conservation.

In this example, the conservation equation is an auxiliary equation and is coupled with the differential equations for integration.

Time Variable

You must provide a time variable in the data set. The name of the time variable defaults to TIME. You can use other variables as the time variable by specifying the TIME= option in the FIT or SOLVE statement. The time intervals need not be evenly spaced. If the time variable for the current observation is less than the time variable for the previous observation, the integration is restarted.

Differential Equations and Goal Seeking

Consider the following differential equation

$$y' = a*x$$

and the data set

```
data t2;
  y=0; time=0; output;
  y=2; time=1; output;
  y=3; time=2; output;
run;
```

The problem is to find values for X that satisfy the differential equation and the data in the data set. Problems of this kind are sometimes referred to as *goal-seeking problems* because they require you to search for values of X that satisfy the goal of Y.

This problem is solved with the following statements:

```
proc model data=t2;
  independent x 0;
  dependent y;
  parm a 5;
  dert.y = a * x;
  solve x / out=goaldata;
run;

proc print data=goaldata;
run;
```

The output from the PROC PRINT statement is shown in [Figure 18.52](#).

Figure 18.52 Dynamic Solution

Obs	_TYPE_	_MODE_	_ERRORS_	x	y	time
1	PREDICT	SIMULATE	0	0.0	0	0
2	PREDICT	SIMULATE	0	0.8	2	1
3	PREDICT	SIMULATE	0	-0.4	3	2

Note that an initial value of 0 is provided for the X variable because it is undetermined at TIME = 0.

In the preceding goal-seeking example, X is treated as a linear function between each set of data points (see [Figure 18.53](#)).

Figure 18.53 Form of X Used for Integration in Goal Seeking

If you integrate $y' = ax$ manually, you have

$$\begin{aligned}
 x(t) &= \frac{t_f - t}{t_f - t_o} x_o + \frac{t - t_o}{t_f - t_o} x_f \\
 y_f - y_o &= \int_{t_o}^{t_f} ax(t) dt \\
 &= a \frac{1}{t_f - t_o} (t(t_f x_o - t_o x_f) + \frac{1}{2} t^2 (x_f - x_o)) \Big|_{t_o}^{t_f}
 \end{aligned}$$

For observation 2, this reduces to

$$\begin{aligned}
 y_f - y_o &= \frac{1}{2} a * x_f \\
 2 &= 2.5 * x_f
 \end{aligned}$$

So $x = 0.8$ for this observation.

Goal seeking for the TIME variable is not allowed.

Restrictions and Bounds on Parameters

Using the BOUNDS and RESTRICT statements, PROC MODEL can compute optimal estimates subject to equality or inequality constraints on the parameter estimates.

Equality restrictions can be written as a vector function:

$$\mathbf{h}(\theta) = 0$$

Inequality restrictions are either active or inactive. When an inequality restriction is active, it is treated as an equality restriction. All inactive inequality restrictions can be written as a vector function:

$$F(\theta) \geq 0$$

Strict inequalities, such as $(f(\theta) > 0)$, are transformed into inequalities as $f(\theta) \times (1 - \epsilon) - \epsilon \geq 0$, where the tolerance ϵ is controlled by the EPSILON= option in the FIT statement and defaults to 10^{-8} . The i th inequality restriction becomes active if $F_i < 0$ and remains active until its Lagrange multiplier becomes negative. Lagrange multipliers are computed for all the nonredundant equality restrictions and all the active inequality restrictions.

For the following, assume the vector $\mathbf{h}(\theta)$ contains all the current active restrictions. The constraint matrix \mathbf{A} is

$$\mathbf{A}(\hat{\theta}) = \frac{\partial \mathbf{h}(\hat{\theta})}{\partial \hat{\theta}}$$

The covariance matrix for the restricted parameter estimates is computed as

$$\mathbf{Z}(\mathbf{Z}'\mathbf{H}\mathbf{Z})^{-1}\mathbf{Z}'$$

where \mathbf{H} is Hessian or approximation to the Hessian of the objective function $((\mathbf{X}'(\text{diag}(\mathbf{S})^{-1} \otimes \mathbf{I})\mathbf{X})$ for OLS), and \mathbf{Z} is the last $(np - nc)$ columns of \mathbf{Q} . \mathbf{Q} is from an LQ factorization of the constraint matrix, nc is the number of active constraints, and np is the number of parameters. See Gill, Murray, and Wright (1981) for more details on LQ factorization. The covariance column in Table 18.2 summarizes the Hessian approximation used for each estimation method.

The covariance matrix for the Lagrange multipliers is computed as

$$(\mathbf{A}\mathbf{H}^{-1}\mathbf{A}')^{-1}$$

The p -value reported for a restriction is computed from a beta distribution rather than a t distribution because the numerator and the denominator of the t ratio for an estimated Lagrange multiplier are not independent.

The Lagrange multipliers for the active restrictions are printed with the parameter estimates. The Lagrange multiplier estimates are computed using the relationship

$$\mathbf{A}'\lambda = \mathbf{g}$$

where the dimensions of the constraint matrix \mathbf{A} are the number of constraints by the number of parameters, λ is the vector of Lagrange multipliers, and \mathbf{g} is the gradient of the objective function at the final estimates.

The final gradient includes the effects of the estimated \mathbf{S} matrix. For example, for OLS the final gradient would be:

$$\mathbf{g} = \mathbf{X}'(\text{diag}(\mathbf{S})^{-1} \otimes \mathbf{I})\mathbf{r}$$

where \mathbf{r} is the residual vector. Note that when nonlinear restrictions are imposed, the convergence measure R might have values greater than one for some iterations.

Tests on Parameters

In general, the hypothesis tested can be written as

$$H_0 : \mathbf{h}(\theta) = 0$$

where $\mathbf{h}(\theta)$ is a vector-valued function of the parameters θ given by the r expressions specified on the TEST statement.

Let $\hat{\mathbf{V}}$ be the estimate of the covariance matrix of $\hat{\theta}$. Let $\hat{\theta}$ be the unconstrained estimate of θ and $\tilde{\theta}$ be the constrained estimate of θ such that $h(\tilde{\theta}) = 0$. Let

$$\mathbf{A}(\theta) = \partial h(\theta) / \partial \theta \big|_{\hat{\theta}}$$

Let r be the dimension of $h(\theta)$ and n be the number of observations. Using this notation, the test statistics for the three kinds of tests are computed as follows.

The Wald test statistic is defined as

$$W = h'(\hat{\theta}) \left(\mathbf{A}(\hat{\theta}) \hat{\mathbf{V}} \mathbf{A}'(\hat{\theta}) \right)^{-1} h(\hat{\theta})$$

The Wald test is not invariant to reparameterization of the model (Gregory and Veall 1985; Gallant 1987, p. 219). For more information about the theoretical properties of the Wald test, see Phillips and Park (1988).

The Lagrange multiplier test statistic is

$$R = \lambda' \mathbf{A}(\tilde{\theta}) \tilde{\mathbf{V}} \mathbf{A}'(\tilde{\theta}) \lambda$$

where λ is the vector of Lagrange multipliers from the computation of the restricted estimate $\tilde{\theta}$.

The Lagrange multiplier test statistic is equivalent to Rao's efficient score test statistic:

$$R = (\partial L(\tilde{\theta}) / \partial \theta)' \tilde{\mathbf{V}} (\partial L(\tilde{\theta}) / \partial \theta)$$

where L is the log-likelihood function for the estimation method used. For SUR, 3SLS, GMM, and iterated versions of these methods, the likelihood function is computed as

$$L = \text{Objective} \times \text{Nobs} / 2$$

For OLS and 2SLS, the Lagrange multiplier test statistic is computed as:

$$R = [(\partial \hat{S}(\tilde{\theta}) / \partial \theta)' \tilde{\mathbf{V}} (\partial \hat{S}(\tilde{\theta}) / \partial \theta)] / \hat{S}(\tilde{\theta})$$

where $\hat{S}(\tilde{\theta})$ is the corresponding objective function value at the constrained estimate.

The likelihood ratio test statistic is

$$T = 2 \left(L(\hat{\theta}) - L(\tilde{\theta}) \right)$$

where $\tilde{\theta}$ represents the constrained estimate of θ and L is the concentrated log-likelihood value.

For OLS and 2SLS, the likelihood ratio test statistic is computed as:

$$T = (n - nparms) \times (\hat{S}(\tilde{\theta}) - \hat{S}(\hat{\theta})) / \hat{S}(\hat{\theta})$$

This test statistic is an approximation from

$$T = n \times \log \left(1 + \frac{rF}{n - nparms} \right)$$

when the value of $rF/(n - nparms)$ is small (Greene 2004, p. 421).

The likelihood ratio test is not appropriate for models with nonstationary serially correlated errors (Gallant 1987, p. 139). The likelihood ratio test should not be used for dynamic systems, for systems with lagged dependent variables, or with the FIML estimation method unless certain conditions are met (see Gallant 1987, p. 479).

For each kind of test, under the null hypothesis the test statistic is asymptotically distributed as a χ^2 random variable with r degrees of freedom, where r is the number of expressions in the TEST statement. The p -values reported for the tests are computed from the $\chi^2(r)$ distribution and are only asymptotically valid. When both RESTRICT and TEST statements are used in a PROC MODEL step, test statistics are computed by taking into account the constraints imposed by the RESTRICT statement.

Monte Carlo simulations suggest that the asymptotic distribution of the Wald test is a poorer approximation to its small sample distribution than the other two tests. However, the Wald test has the least computational cost, since it does not require computation of the constrained estimate $\tilde{\theta}$.

The following is an example of using the TEST statement to perform a likelihood ratio test for a compound hypothesis.

```
test a*exp(-k) = 1-k, d = 0 ,/ lr;
```

It is important to keep in mind that although individual t tests for each parameter are printed by default into the parameter estimates table, they are only asymptotically valid for nonlinear models. You should be cautious in drawing any inferences from these t tests for small samples.

Hausman Specification Test

Hausman's specification test, or m -statistic, can be used to test hypotheses in terms of bias or inconsistency of an estimator. This test was also proposed by Wu (1973). Hausman's m -statistic is as follows.

Given two estimators, $\hat{\beta}_0$ and $\hat{\beta}_1$, where under the null hypothesis both estimators are consistent but only $\hat{\beta}_0$ is asymptotically efficient and under the alternative hypothesis only $\hat{\beta}_1$ is consistent, the m -statistic is

$$m = \hat{q}'(\hat{\mathbf{V}}_1 - \hat{\mathbf{V}}_0)^{-1}\hat{q}$$

where $\hat{\mathbf{V}}_1$ and $\hat{\mathbf{V}}_0$ represent consistent estimates of the asymptotic covariance matrices of $\hat{\beta}_1$ and $\hat{\beta}_0$ respectively, and

$$q = \hat{\beta}_1 - \hat{\beta}_0$$

The m -statistic is then distributed χ^2 with k degrees of freedom, where k is the rank of the matrix $(\hat{\mathbf{V}}_1 - \hat{\mathbf{V}}_0)$. A generalized inverse is used, as recommended by Hausman and Taylor (1982).

In the MODEL procedure, Hausman's m -statistic can be used to determine if it is necessary to use an instrumental variables method rather than a more efficient OLS estimation. Hausman's m -statistic can also be used to compare 2SLS with 3SLS for a class of estimators for which 3SLS is asymptotically efficient (similarly for OLS and SUR).

Hausman's m -statistic can also be used, in principle, to test the null hypothesis of normality when comparing 3SLS to FIML. Because of the poor performance of this form of the test, it is not offered in the MODEL procedure. See Fair (1984, pp. 246–247) for a discussion of why Hausman's test fails for common econometric models.

To perform a Hausman's specification test, specify the HAUSMAN option in the FIT statement. The selected estimation methods are compared using Hausman's m -statistic.

In the following example, Hausman's test is used to check the presence of measurement error. Under H_0 of no measurement error, OLS is efficient, while under H_1 , 2SLS is consistent. In the following code, OLS and 2SLS are used to estimate the model, and Hausman's test is requested.

```
proc model data=one out=fiml2;
  endogenous y1 y2;

  y1 = py2 * y2 + px1 * x1 + interc;
  y2 = py1* y1 + pz1 * z1 + d2;

  fit y1 y2 / ols 2sls hausman;
  instruments x1 z1;
run;
```

The output specified by the HAUSMAN option produces the results shown in Figure 18.54.

Figure 18.54 Hausman's Specification Test Results

The MODEL Procedure				
Hausman's Specification Test Results				
Efficient under H0	Consistent under H1	DF	Statistic	Pr > ChiSq
OLS	2SLS	6	13.86	0.0313

Figure 18.54 indicates that 2SLS is preferred over OLS at 5% level of significance. In this case, the null hypothesis of no measurement error is rejected. Hence, the instrumental variable estimator is required for this example due to the presence of measurement error.

Chow Tests

The Chow test is used to test for break points or structural changes in a model. The problem is posed as a partitioning of the data into two parts of size n_1 and n_2 . The null hypothesis to be tested is

$$H_0 : \beta_1 = \beta_2 = \beta$$

where β_1 is estimated by using the first part of the data and β_2 is estimated by using the second part.

The test is performed as follows (see Davidson and MacKinnon 1993, p. 380).

1. The p parameters of the model are estimated.
2. A second linear regression is performed on the residuals, \hat{u} , from the nonlinear estimation in step one.

$$\hat{u} = \hat{\mathbf{X}}b + \text{residuals}$$

where $\hat{\mathbf{X}}$ is Jacobian columns that are evaluated at the parameter estimates. If the estimation is an instrumental variables estimation with matrix of instruments \mathbf{W} , then the following regression is performed:

$$\hat{u} = \mathbf{P}_{W^*}\hat{\mathbf{X}}b + \text{residuals}$$

where \mathbf{P}_{W^*} is the projection matrix.

3. The restricted SSE (RSSE) from this regression is obtained. An SSE for each subsample is then obtained by using the same linear regression.
4. The F statistic is then

$$f = \frac{(RSSE - SSE_1 - SSE_2)/p}{(SSE_1 + SSE_2)/(n - 2p)}$$

This test has p and $n - 2p$ degrees of freedom.

Chow's test is not applicable if $\min(n_1, n_2) < p$, since one of the two subsamples does not contain enough data to estimate β . In this instance, the *predictive Chow test* can be used. The predictive Chow test is defined as

$$f = \frac{(RSSE - SSE_1) \times (n_1 - p)}{SSE_1 * n_2}$$

where $n_1 > p$. This test can be derived from the Chow test by noting that the $SSE_2 = 0$ when $n_2 \leq p$ and by adjusting the degrees of freedom appropriately.

You can select the Chow test and the predictive Chow test by specifying the `CHOW=arg` and the `PCHOW=arg` options in the FIT statement, where `arg` is either the number of observations in the first sample or a parenthesized list of first sample sizes. If the size of the one of the two groups in which the sample is partitioned is less than the number of parameters, then a predictive Chow test is automatically used. These tests statistics are not produced for GMM and FIML estimations.

The following is an example of the use of the Chow test.

```

data exp;
  x=0;
  do time=1 to 100;
    if time=50 then x=1;
    y = 35 * exp( 0.01 * time ) + rannor( 123 ) + x * 5;
    output;
  end;
run;

proc model data=exp;
  parm zo 35 b;
  dert.z = b * z;
  y=z;
  fit y init=(z=zo) / chow =(40 50 60) pchow=90;
run;

```

The data set introduces an artificial structural change into the model (the structural change effects the intercept parameter). The output from the requested Chow tests are shown in Figure 18.55.

Figure 18.55 Chow's Test Results

The MODEL Procedure					
Structural Change Test					
Test	Break Point	Num DF	Den DF	F Value	Pr > F
Chow	40	2	96	12.95	<.0001
Chow	50	2	96	101.37	<.0001
Chow	60	2	96	26.43	<.0001
Predictive Chow	90	11	87	1.86	0.0566

Profile Likelihood Confidence Intervals

Wald-based and likelihood-ratio-based confidence intervals are available in the MODEL procedure for computing a confidence interval on an estimated parameter. A confidence interval on a parameter θ can be constructed by inverting a Wald-based or a likelihood-ratio-based test.

The approximate $100(1 - \alpha)$ % Wald confidence interval for a parameter θ is

$$\hat{\theta} \pm z_{1-\alpha/2} \hat{\sigma}$$

where z_p is the $100p$ th percentile of the standard normal distribution, $\hat{\theta}$ is the maximum likelihood estimate of θ , and $\hat{\sigma}$ is the standard error estimate of $\hat{\theta}$.

A likelihood-ratio-based confidence interval is derived from the χ^2 distribution of the generalized likelihood ratio test. The approximate $1 - \alpha$ confidence interval for a parameter θ is

$$\theta : 2[l(\hat{\theta}) - l(\theta)] \leq q_{1,1-\alpha} = 2l^*$$

where $q_{1,1-\alpha}$ is the $(1 - \alpha)$ quantile of the χ^2 with one degree of freedom, and $l(\theta)$ is the log likelihood as a function of one parameter. The endpoints of a confidence interval are the zeros of the function $l(\theta) - l^*$. Computing a likelihood-ratio-based confidence interval is an iterative process. This process must be performed twice for each parameter, so the computational cost is considerable. Using a modified form of the algorithm recommended by Venzon and Moolgavkar (1988), you can determine that the cost of each endpoint computation is approximately the cost of estimating the original system.

To request confidence intervals on estimated parameters, specify the PRL= option in the FIT statement. By default, the PRL option produces 95% likelihood ratio confidence limits. The coverage of the confidence interval is controlled by the ALPHA= option in the FIT statement.

The following is an example of the use of the confidence interval options.

```
data exp;
  do time = 1 to 20;
    y = 35 * exp( 0.01 * time ) + 5*rannor( 123 );
  output;
  end;
run;

proc model data=exp;
  parm zo 35 b;
  dert.z = b * z;
  y=z;
  fit y init=(z=zo) / prl=both;
  test zo = 40.475437 ,/ lr;
run;
```

The output from the requested confidence intervals and the TEST statement are shown in Figure 18.56

Figure 18.56 Confidence Interval Estimation

The MODEL Procedure				
Nonlinear OLS Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
zo	36.58933	1.9471	18.79	<.0001
b	0.006497	0.00464	1.40	0.1780
Test Results				
Test	Type	Statistic	Pr > ChiSq	Label
Test0	L.R.	3.81	0.0509	zo = 40.475437
Parameter Wald				
95% Confidence Intervals				
Parameter	Value	Lower	Upper	
zo	36.5893	32.7730	40.4056	
b	0.00650	-0.00259	0.0156	

Figure 18.56 continued

Parameter	Parameter Likelihood Ratio 95% Confidence Intervals		
	Value	Lower	Upper
zo	36.5893	32.8381	40.4921
b	0.00650	-0.00264	0.0157

In this example the parameter value used in the likelihood ratio test, $z_o = 40.475437$, is close to the upper bound computed for the likelihood ratio confidence interval, $z_o \leq 40.4921$. This coincidence is not germane to the analysis however, since the likelihood ratio test is a test of the null hypothesis $H_0 : z_o = 40.475437$ and the confidence interval can be viewed as a test of the null hypothesis $H_0 : 32.8381 \leq z_o \leq 40.4921$.

Choice of Instruments

Several of the estimation methods supported by PROC MODEL are instrumental variables methods. There is no standard method for choosing instruments for nonlinear regression. Few econometric textbooks discuss the selection of instruments for nonlinear models. See Bowden and Turkington (1984, pp. 180–182) for more information.

The purpose of the instrumental projection is to purge the regressors of their correlation with the residual. For nonlinear systems, the regressors are the partials of the residuals with respect to the parameters.

Possible instrumental variables include the following:

- any variable in the model that is independent of the errors
- lags of variables in the system
- derivatives with respect to the parameters, if the derivatives are independent of the errors
- low-degree polynomials in the exogenous variables
- variables from the data set or functions of variables from the data set

Selected instruments must not have any of the following characteristics:

- depend on any variable endogenous with respect to the equations estimated
- depend on any of the parameters estimated
- be lags of endogenous variables if there is serial correlation of the errors

If the preceding rules are satisfied and there are enough observations to support the number of instruments used, the results should be consistent and the efficiency loss held to a minimum.

You need at least as many instruments as the maximum number of parameters in any equation, or some of the parameters cannot be estimated. Note that *number of instruments* means linearly independent instruments. If you add an instrument that is a linear combination of other instruments, it has no effect and does not increase the effective number of instruments.

You can, however, use too many instruments. In order to get the benefit of instrumental variables, you must have more observations than instruments. Thus, there is a trade-off; the instrumental variables technique completely eliminates the simultaneous equation bias only in large samples. In finite samples, the larger the excess of observations over instruments, the more the bias is reduced. Adding more instruments might improve the efficiency, but after some point efficiency declines as the excess of observations over instruments becomes smaller and the bias grows.

The instruments used in an estimation are printed out at the beginning of the estimation. For example, the following statements produce the instruments list shown in [Figure 18.57](#).

```
proc model data=test2;
  exogenous x1 x2;
  parms b1 a1 a2 b2 2.5 c2 55;
  y1 = a1 * y2 + b1 * exp(x1);
  y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2;
  fit y1 y2 / n2s1s;
  inst b1 b2 c2 x1 ;
run;
```

Figure 18.57 Instruments Used Message

```

                                The MODEL Procedure

                                The 2 Equations to Estimate

                                y1 = F(b1, a1(y2))
                                y2 = F(a2(y1), b2, c2)
                                Instruments 1 x1 @y1/@b1 @y2/@b2 @y2/@c2
```

This states that an intercept term, the exogenous variable X1, and the partial derivatives of the equations with respect to B1, B2, and C2, were used as instruments for the estimation.

Examples

Suppose that Y1 and Y2 are endogenous variables, that X1 and X2 are exogenous variables, and that A, B, C, D, E, F, and G are parameters. Consider the following model:

```
y1 = a + b * x1 + c * y2 + d * lag(y1);
y2 = e + f * x2 + g * y1;
fit y1 y2;
instruments exclude=(c g);
```

The INSTRUMENTS statement produces X1, X2, LAG(Y1), and an intercept as instruments.

In order to estimate the Y1 equation by itself, it is necessary to include X2 explicitly in the instruments since F, in this case, is not included in the following estimation:

```
y1 = a + b * x1 + c * y2 + d * lag(y1);
y2 = e + f * x2 + g * y1;
fit y1;
instruments x2 exclude=(c);
```

This produces the same instruments as before. You can list the parameter associated with the lagged variable as an instrument instead of using the EXCLUDE= option. Thus, the following is equivalent to the previous example:

```
y1 = a + b * x1 + c * y2 + d * lag(y1);
y2 = e + f * x2 + g * y1;
fit y1;
instruments x1 x2 d;
```

For an example of declaring instruments when estimating a model involving identities, consider Klein's Model I:

```
proc model data=klien;
  endogenous c p w i x wsum k y;
  exogenous wp g t year;
  parms c0-c3 i0-i3 w0-w3;
  a: c = c0 + c1 * p + c2 * lag(p) + c3 * wsum;
  b: i = i0 + i1 * p + i2 * lag(p) + i3 * lag(k);
  c: w = w0 + w1 * x + w2 * lag(x) + w3 * year;
  x = c + i + g;
  y = c + i + g-t;
  p = x-w-t;
  k = lag(k) + i;
  wsum = w + wp;
run;
```

The three equations to estimate are identified by the labels A, B, and C. The parameters associated with the predetermined terms are C2, I2, I3, W2, and W3 (and the intercepts, which are automatically added to the instruments). In addition, the system includes five identities that contain the predetermined variables G, T, LAG(K), and WP. Thus, the INSTRUMENTS statement can be written as

```
lagk = lag(k);
instruments c2 i2 i3 w2 w3 g t wp lagk;
```

where LAGK is a program variable used to hold LAG(K). However, this is more complicated than it needs to be. Except for LAG(K), all the predetermined terms in the identities are exogenous

variables, and LAG(K) is already included as the coefficient of I3. There are also more parameters for predetermined terms than for endogenous terms, so you might prefer to use the EXCLUDE= option. Thus, you can specify the same instruments list with the simpler statement

```
instruments _exog_ exclude=(c1 c3 i1 w1);
```

To illustrate the use of polynomial terms as instrumental variables, consider the following model:

$$y_1 = a + b * \exp(c * x_1) + d * \log(x_2) + e * \exp(f * y_2);$$

The parameters are A, B, C, D, E, and F, and the right-hand-side variables are X1, X2, and Y2. Assume that X1 and X2 are exogenous (independent of the error), while Y2 is endogenous. The equation for Y2 is not specified, but assume that it includes the variables X1, X3, and Y1, with X3 exogenous, so the exogenous variables of the full system are X1, X2, and X3. Using as instruments quadratic terms in the exogenous variables, the model is specified to PROC MODEL as follows:

```
proc model;
  parms a b c d e f;
  y1 = a + b * exp( c * x1 ) + d * log( x2 ) + e * exp( f * y2 );
  instruments inst1-inst9;
  inst1 = x1; inst2 = x2; inst3 = x3;
  inst4 = x1 * x1; inst5 = x1 * x2; inst6 = x1 * x3;
  inst7 = x2 * x2; inst8 = x2 * x3; inst9 = x3 * x3;
  fit y1 / 2s1s;
run;
```

It is not clear what degree polynomial should be used. There is no way to know how good the approximation is for any degree chosen, although the first-stage R^2 s might help the assessment.

First-Stage R-Squares

When the FSRSQ option is used on the FIT statement, the MODEL procedure prints a column of first-stage R^2 (FSRSQ) statistics along with the parameter estimates. The FSRSQ measures the fraction of the variation of the derivative column associated with the parameter that remains after projection through the instruments.

Ideally, the FSRSQ should be very close to 1.00 for exogenous derivatives. If the FSRSQ is small for an endogenous derivative, it is unclear whether this reflects a poor choice of instruments or a large influence of the errors in the endogenous right-hand-side variables. When the FSRSQ for one or more parameters is small, the standard errors of the parameter estimates are likely to be large.

Note that you can make all the FSRSQs larger (or 1.00) by including more instruments, because of the disadvantage discussed previously. The FSRSQ statistics reported are unadjusted R^2 s and do not include a degrees-of-freedom correction.

Autoregressive Moving-Average Error Processes

Autoregressive moving-average error processes (ARMA errors) and other models that involve lags of error terms can be estimated by using FIT statements and simulated or forecast by using SOLVE statements. ARMA models for the error process are often used for models with autocorrelated residuals. The %AR macro can be used to specify models with autoregressive error processes. The %MA macro can be used to specify models with moving-average error processes.

Autoregressive Errors

A model with first-order autoregressive errors, AR(1), has the form

$$y_t = f(x_t, \theta) + \mu_t$$

$$\mu_t = \phi\mu_{t-1} + \epsilon_t$$

while an AR(2) error process has the form

$$\mu_t = \phi_1\mu_{t-1} + \phi_2\mu_{t-2} + \epsilon_t$$

and so forth for higher-order processes. Note that the ϵ_t 's are independent and identically distributed and have an expected value of 0.

An example of a model with an AR(2) component is

$$y = \alpha + \beta x_1 + \mu_t$$

$$\mu_t = \phi_1\mu_{t-1} + \phi_2\mu_{t-2} + \epsilon_t$$

You would write this model as

```
proc model data=in;
  parms a b p1 p2;
  y = a + b * x1 + p1 * zlag1(y - (a + b * x1)) +
      p2 * zlag2(y - (a + b * x1));
  fit y;
run;
```

or equivalently using the %AR macro as

```
proc model data=in;
  parms a b;
  y = a + b * x1;
  %ar( y, 2 );
  fit y;
run;
```

Moving-Average Models

A model with first-order moving-average errors, MA(1), has the form

$$y_t = f(x_t) + \mu_t$$

$$\mu_t = \epsilon_t - \theta_1 \epsilon_{t-1}$$

where ϵ_t is identically and independently distributed with mean zero. An MA(2) error process has the form

$$\mu_t = \epsilon_t - \theta_1 \epsilon_{t-1} - \theta_2 \epsilon_{t-2}$$

and so forth for higher-order processes.

For example, you can write a simple linear regression model with MA(2) moving-average errors as

```
proc model data=inma2;
  parms a b ma1 ma2;
  y = a + b * x + ma1 * zlag1( resid.y ) +
      ma2 * zlag2( resid.y );
  fit;
run;
```

where MA1 and MA2 are the moving-average parameters.

Note that RESID.Y is automatically defined by PROC MODEL as

```
pred.y = a + b * x + ma1 * zlag1( resid.y ) +
        ma2 * zlag2( resid.y );
resid.y = pred.y - actual.y;
```

Note that RESID.Y is negative of ϵ_t .

The ZLAG function must be used for MA models to truncate the recursion of the lags. This ensures that the lagged errors start at zero in the lag-priming phase and do not propagate missing values when lag-priming period variables are missing, and it ensures that the future errors are zero rather than missing during simulation or forecasting. For details about the lag functions, see the section “Lag Logic” on page 1210.

This model written using the %MA macro is as follows:

```
proc model data=inma2;
  parms a b;
  y = a + b * x;
  %ma(y, 2);
  fit;
run;
```

General Form for ARMA Models

The general ARMA(p,q) process has the following form

$$\mu_t = \phi_1\mu_{t-1} + \dots + \phi_p\mu_{t-p} + \epsilon_t - \theta_1\epsilon_{t-1} - \dots - \theta_q\epsilon_{t-q}$$

An ARMA(p,q) model can be specified as follows:

```
yhat = ... compute structural predicted value here ... ;
yarma = ar1 * zlag1( y - yhat ) + ... /* ar part */
          + ar(p) * zlag(p)( y - yhat )
          + ma1 * zlag1( resid.y ) + ... /* ma part */
          + ma(q) * zlag(q)( resid.y );
y = yhat + yarma;
```

where AR i and MA j represent the autoregressive and moving-average parameters for the various lags. You can use any names you want for these variables, and there are many equivalent ways that the specification could be written.

Vector ARMA processes can also be estimated with PROC MODEL. For example, a two-variable AR(1) process for the errors of the two endogenous variables Y1 and Y2 can be specified as follows:

```
y1hat = ... compute structural predicted value here ... ;

y1      = y1hat + ar1_1 * zlag1( y1 - y1hat ) /* ar part y1,y1 */
          + ar1_2 * zlag1( y2 - y2hat ); /* ar part y1,y2 */

y21hat = ... compute structural predicted value here ... ;

y2      = y2hat + ar2_2 * zlag1( y2 - y2hat ) /* ar part y2,y2 */
          + ar2_1 * zlag1( y1 - y1hat ); /* ar part y2,y1 */
```

Convergence Problems with ARMA Models

ARMA models can be difficult to estimate. If the parameter estimates are not within the appropriate range, a moving-average model's residual terms grow exponentially. The calculated residuals for later observations can be very large or can overflow. This can happen either because improper starting values were used or because the iterations moved away from reasonable values.

Care should be used in choosing starting values for ARMA parameters. Starting values of 0.001 for ARMA parameters usually work if the model fits the data well and the problem is well-conditioned. Note that an MA model can often be approximated by a high-order AR model, and vice versa. This can result in high collinearity in mixed ARMA models, which in turn can cause serious ill-conditioning in the calculations and instability of the parameter estimates.

If you have convergence problems while estimating a model with ARMA error processes, try to estimate in steps. First, use a FIT statement to estimate only the structural parameters with the ARMA parameters held to zero (or to reasonable prior estimates if available). Next, use another FIT

statement to estimate the ARMA parameters only, using the structural parameter values from the first run. Since the values of the structural parameters are likely to be close to their final estimates, the ARMA parameter estimates might now converge. Finally, use another FIT statement to produce simultaneous estimates of all the parameters. Since the initial values of the parameters are now likely to be quite close to their final joint estimates, the estimates should converge quickly if the model is appropriate for the data.

AR Initial Conditions

The initial lags of the error terms of AR(p) models can be modeled in different ways. The autoregressive error startup methods supported by SAS/ETS procedures are the following:

CLS	conditional least squares (ARIMA and MODEL procedures)
ULS	unconditional least squares (AUTOREG, ARIMA, and MODEL procedures)
ML	maximum likelihood (AUTOREG, ARIMA, and MODEL procedures)
YW	Yule-Walker (AUTOREG procedure only)
HL	Hildreth-Lu, which deletes the first p observations (MODEL procedure only)

See Chapter 8, “The AUTOREG Procedure,” for an explanation and discussion of the merits of various AR(p) startup methods.

The CLS, ULS, ML, and HL initializations can be performed by PROC MODEL. For AR(1) errors, these initializations can be produced as shown in Table 18.3. These methods are equivalent in large samples.

Table 18.3 Initializations Performed by PROC MODEL: AR(1) ERRORS

Method	Formula
conditional least squares	$Y = \hat{Y} + AR1 * ZLAG1(Y - \hat{Y});$
unconditional least squares	$Y = \hat{Y} + AR1 * ZLAG1(Y - \hat{Y});$ IF _OBS_=1 THEN RESID.Y=SQRT(1-AR1**2)*RESID.Y;
maximum likelihood	$Y = \hat{Y} + AR1 * ZLAG1(Y - \hat{Y});$ $W = (1 - AR1**2)**(-1/(2 * _NUSED_));$ IF _OBS_=1 THEN $W = W * SQRT(1 - AR1**2);$ RESID.Y=W*RESID.Y;
Hildreth-Lu	$Y = \hat{Y} + AR1 * LAG1(Y - \hat{Y});$

MA Initial Conditions

The initial lags of the error terms of $MA(q)$ models can also be modeled in different ways. The following moving-average error start-up paradigms are supported by the ARIMA and MODEL procedures:

ULS	unconditional least squares
CLS	conditional least squares
ML	maximum likelihood

The conditional least squares method of estimating moving-average error terms is not optimal because it ignores the start-up problem. This reduces the efficiency of the estimates, although they remain unbiased. The initial lagged residuals, extending before the start of the data, are assumed to be 0, their unconditional expected value. This introduces a difference between these residuals and the generalized least squares residuals for the moving-average covariance, which, unlike the autoregressive model, persists through the data set. Usually this difference converges quickly to 0, but for nearly noninvertible moving-average processes the convergence is quite slow. To minimize this problem, you should have plenty of data, and the moving-average parameter estimates should be well within the invertible range.

This problem can be corrected at the expense of writing a more complex program. Unconditional least squares estimates for the $MA(1)$ process can be produced by specifying the model as follows:

```

yhat = ... compute structural predicted value here ... ;
if _obs_ = 1 then do;
  h = sqrt( 1 + mal ** 2 );
  y = yhat;
  resid.y = ( y - yhat ) / h;
end;
else do;
  g = mal / zlag1( h );
  h = sqrt( 1 + mal ** 2 - g ** 2 );
  y = yhat + g * zlag1( resid.y );
  resid.y = ( ( y - yhat ) - g * zlag1( resid.y ) ) / h;
end;

```

Moving-average errors can be difficult to estimate. You should consider using an $AR(p)$ approximation to the moving-average process. A moving-average process can usually be well-approximated by an autoregressive process if the data have not been smoothed or differenced.

The %AR Macro

The SAS macro `%AR` generates programming statements for PROC MODEL for autoregressive models. The `%AR` macro is part of SAS/ETS software, and no special options need to be set to use the macro. The autoregressive process can be applied to the structural equation errors or to the endogenous series themselves.

The %AR macro can be used for the following types of autoregression:

- univariate autoregression
- unrestricted vector autoregression
- restricted vector autoregression

Univariate Autoregression

To model the error term of an equation as an autoregressive process, use the following statement after the equation:

```
%ar( varname, nlags )
```

For example, suppose that Y is a linear function of X1, X2, and an AR(2) error. You would write this model as follows:

```
proc model data=in;
  parms a b c;
  y = a + b * x1 + c * x2;
  %ar( y, 2 )
  fit y / list;
run;
```

The calls to %AR must come *after* all of the equations that the process applies to.

The preceding macro invocation, %AR(y,2), produces the statements shown in the LIST output in Figure 18.58.

Figure 18.58 LIST Option Output for an AR(2) Model

The MODEL Procedure		
Listing of Compiled Program Code		
Stmt	Line:Col	Statement as Parsed
1	2148:4	PRED.y = a + b * x1 + c * x2;
1	2148:4	RESID.y = PRED.y - ACTUAL.y;
1	2148:4	ERROR.y = PRED.y - y;
2	2149:14	_PRED__y = PRED.y;
3	2149:15	_OLD_PRED.y = PRED.y + y_l1
		* ZLAG1(y - _PRED__y) + y_l2
		* ZLAG2(y - _PRED__y);
3	2149:15	PRED.y = _OLD_PRED.y;
3	2149:15	RESID.y = PRED.y - ACTUAL.y;
3	2149:15	ERROR.y = PRED.y - y;

The `_PRED__` prefixed variables are temporary program variables used so that the lags of the residuals are the correct residuals and not the ones redefined by this equation. Note that this is equivalent to the statements explicitly written in the section “General Form for ARMA Models” on page 1140.

You can also restrict the autoregressive parameters to zero at selected lags. For example, if you wanted autoregressive parameters at lags 1, 12, and 13, you can use the following statements:

```
proc model data=in;
  parms a b c;
  y = a + b * x1 + c * x2;
  %ar( y, 13, , 1 12 13 )
  fit y / list;
run;
```

These statements generate the output shown in Figure 18.59.

Figure 18.59 LIST Option Output for an AR Model with Lags at 1, 12, and 13

The MODEL Procedure		
Listing of Compiled Program Code		
Stmt	Line:Col	Statement as Parsed
1	2157:4	PRED.y = a + b * x1 + c * x2;
1	2157:4	RESID.y = PRED.y - ACTUAL.y;
1	2157:4	ERROR.y = PRED.y - y;
2	2158:14	_PRED_y = PRED.y;
3	2158:15	_OLD_PRED.y = PRED.y + y_11 * ZLAG1(y - _PRED_y) + y_112 * ZLAG12(y - _PRED_y) + y_113 * ZLAG13(y - _PRED_y);
3	2158:15	PRED.y = _OLD_PRED.y;
3	2158:15	RESID.y = PRED.y - ACTUAL.y;
3	2158:15	ERROR.y = PRED.y - y;

There are variations on the conditional least squares method, depending on whether observations at the start of the series are used to “warm up” the AR process. By default, the `%AR` conditional least squares method uses all the observations and assumes zeros for the initial lags of autoregressive terms. By using the `M=` option, you can request that `%AR` use the unconditional least squares (ULS) or maximum-likelihood (ML) method instead. For example,

```
proc model data=in;
  y = a + b * x1 + c * x2;
  %ar( y, 2, m=uls )
  fit y;
run;
```

Discussions of these methods is provided in the section “AR Initial Conditions” on page 1141.

By using the `M=CLS n` option, you can request that the first n observations be used to compute estimates of the initial autoregressive lags. In this case, the analysis starts with observation $n + 1$. For example:

```

proc model data=in;
  y = a + b * x1 + c * x2;
  %ar( y, 2, m=cls2 )
  fit y;
run;

```

You can use the %AR macro to apply an autoregressive model to the endogenous variable, instead of to the error term, by using the TYPE=V option. For example, if you want to add the five past lags of Y to the equation in the previous example, you could use %AR to generate the parameters and lags by using the following statements:

```

proc model data=in;
  parms a b c;
  y = a + b * x1 + c * x2;
  %ar( y, 5, type=v )
  fit y / list;
run;

```

The preceding statements generate the output shown in Figure 18.60.

Figure 18.60 LIST Option Output for an AR model of Y

The MODEL Procedure		
Listing of Compiled Program Code		
Stmt	Line:Col	Statement as Parsed
1	2180:4	PRED.y = a + b * x1 + c * x2;
1	2180:4	RESID.y = PRED.y - ACTUAL.y;
1	2180:4	ERROR.y = PRED.y - y;
2	2181:15	_OLD_PRED.y = PRED.y + y_l1 * ZLAG1(y) + y_l2 * ZLAG2(y) + y_l3 * ZLAG3(y) + y_l4 * ZLAG4(y) + y_l5 * ZLAG5(y);
2	2181:15	PRED.y = _OLD_PRED.y;
2	2181:15	RESID.y = PRED.y - ACTUAL.y;
2	2181:15	ERROR.y = PRED.y - y;

This model predicts Y as a linear combination of X1, X2, an intercept, and the values of Y in the most recent five periods.

Unrestricted Vector Autoregression

To model the error terms of a set of equations as a vector autoregressive process, use the following form of the %AR macro after the equations:

```
%ar( process_name, nlags, variable_list )
```

The *process_name* value is any name that you supply for %AR to use in making names for the autoregressive parameters. You can use the %AR macro to model several different AR processes for

different sets of equations by using different process names for each set. The process name ensures that the variable names used are unique. Use a short *process_name* value for the process if parameter estimates are to be written to an output data set. The %AR macro tries to construct parameter names less than or equal to eight characters, but this is limited by the length of *process_name*, which is used as a prefix for the AR parameter names.

The *variable_list* value is the list of endogenous variables for the equations.

For example, suppose that errors for equations Y1, Y2, and Y3 are generated by a second-order vector autoregressive process. You can use the following statements:

```
proc model data=in;
  y1 = ... equation for y1 ...;
  y2 = ... equation for y2 ...;
  y3 = ... equation for y3 ...;
  %ar( name, 2, y1 y2 y3 )
  fit y1 y2 y3;
run;
```

which generate the following for Y1 and similar code for Y2 and Y3:

```
y1 = pred.y1 + name1_1_1*zlag1(y1-name_y1) +
      name1_1_2*zlag1(y2-name_y2) +
      name1_1_3*zlag1(y3-name_y3) +
      name2_1_1*zlag2(y1-name_y1) +
      name2_1_2*zlag2(y2-name_y2) +
      name2_1_3*zlag2(y3-name_y3) ;
```

Only the conditional least squares (M=CLS or M=CLS_n) method can be used for vector processes.

You can also use the same form with restrictions that the coefficient matrix be 0 at selected lags. For example, the following statements apply a third-order vector process to the equation errors with all the coefficients at lag 2 restricted to 0 and with the coefficients at lags 1 and 3 unrestricted:

```
proc model data=in;
  y1 = ... equation for y1 ...;
  y2 = ... equation for y2 ...;
  y3 = ... equation for y3 ...;
  %ar( name, 3, y1 y2 y3, 1 3 )
  fit y1 y2 y3;
```

You can model the three series Y1–Y3 as a vector autoregressive process in the variables instead of in the errors by using the TYPE=V option. If you want to model Y1–Y3 as a function of past values of Y1–Y3 and some exogenous variables or constants, you can use %AR to generate the statements for the lag terms. Write an equation for each variable for the nonautoregressive part of the model, and then call %AR with the TYPE=V option. For example,

```
proc model data=in;
  parms a1-a3 b1-b3;
```

```

y1 = a1 + b1 * x;
y2 = a2 + b2 * x;
y3 = a3 + b3 * x;
%ar( name, 2, y1 y2 y3, type=v )
fit y1 y2 y3;
run;

```

The nonautoregressive part of the model can be a function of exogenous variables, or it can be intercept parameters. If there are no exogenous components to the vector autoregression model, including no intercepts, then assign zero to each of the variables. There must be an assignment to each of the variables before %AR is called.

```

proc model data=in;
  y1=0;
  y2=0;
  y3=0;
  %ar( name, 2, y1 y2 y3, type=v )
  fit y1 y2 y3;
run;

```

This example models the vector $Y=(Y1\ Y2\ Y3)'$ as a linear function only of its value in the previous two periods and a white noise error vector. The model has $18=(3 \times 3 + 3 \times 3)$ parameters.

Syntax of the %AR Macro

There are two cases of the syntax of the %AR macro. When restrictions on a vector AR process are not needed, the syntax of the %AR macro has the general form

```
%AR ( name , nlag <,endolist <, laglist >> <,M= method > <,TYPE= V> );
```

where

- | | |
|-----------------|--|
| <i>name</i> | specifies a prefix for %AR to use in constructing names of variables needed to define the AR process. If the <i>endolist</i> is not specified, the endogenous list defaults to <i>name</i> , which must be the name of the equation to which the AR error process is to be applied. The <i>name</i> value cannot exceed 32 characters. |
| <i>nlag</i> | is the order of the AR process. |
| <i>endolist</i> | specifies the list of equations to which the AR process is to be applied. If more than one name is given, an unrestricted vector process is created with the structural residuals of all the equations included as regressors in each of the equations. If not specified, <i>endolist</i> defaults to <i>name</i> . |
| <i>laglist</i> | specifies the list of lags at which the AR terms are to be added. The coefficients of the terms at lags not listed are set to 0. All of the listed lags must be less than or equal to <i>nlag</i> , and there must be no duplicates. If not specified, the <i>laglist</i> defaults to all lags 1 through <i>nlag</i> . |
| <i>M=method</i> | specifies the estimation method to implement. Valid values of M= are CLS (conditional least squares estimates), ULS (unconditional least squares estimates), and ML (maximum likelihood estimates). M=CLS is the default. Only M=CLS |

is allowed when more than one equation is specified. The ULS and ML methods are not supported for vector AR models by %AR.

TYPE=V specifies that the AR process is to be applied to the endogenous variables themselves instead of to the structural residuals of the equations.

Restricted Vector Autoregression

You can control which parameters are included in the process, restricting to 0 those parameters that you do not include. First, use %AR with the DEFER option to declare the variable list and define the dimension of the process. Then, use additional %AR calls to generate terms for selected equations with selected variables at selected lags. For example,

```
proc model data=d;
  y1 = ... equation for y1 ...;
  y2 = ... equation for y2 ...;
  y3 = ... equation for y3 ...;
  %ar( name, 2, y1 y2 y3, defer )
  %ar( name, y1, y1 y2 )
  %ar( name, y2 y3, , 1 )
  fit y1 y2 y3;
run;
```

The error equations produced are as follows:

```
y1 = pred.y1 + name1_1_1*zlag1(y1-name_y1) +
      name1_1_2*zlag1(y2-name_y2) + name2_1_1*zlag2(y1-name_y1) +
      name2_1_2*zlag2(y2-name_y2) ;
y2 = pred.y2 + name1_2_1*zlag1(y1-name_y1) +
      name1_2_2*zlag1(y2-name_y2) + name1_2_3*zlag1(y3-name_y3) ;
y3 = pred.y3 + name1_3_1*zlag1(y1-name_y1) +
      name1_3_2*zlag1(y2-name_y2) + name1_3_3*zlag1(y3-name_y3) ;
```

This model states that the errors for Y1 depend on the errors of both Y1 and Y2 (but not Y3) at both lags 1 and 2, and that the errors for Y2 and Y3 depend on the previous errors for all three variables, but only at lag 1.

%AR Macro Syntax for Restricted Vector AR

An alternative use of %AR is allowed to impose restrictions on a vector AR process by calling %AR several times to specify different AR terms and lags for different equations.

The first call has the general form

```
%AR( name, nlag, endolist , DEFER ) ;
```

where

<i>name</i>	specifies a prefix for %AR to use in constructing names of variables needed to define the vector AR process.
<i>nlag</i>	specifies the order of the AR process.
<i>endolist</i>	specifies the list of equations to which the AR process is to be applied.
DEFER	specifies that %AR is not to generate the AR process but is to wait for further information specified in later %AR calls for the same <i>name</i> value.

The subsequent calls have the general form

```
%AR( name, eqlist, varlist, laglist, TYPE= )
```

where

<i>name</i>	is the same as in the first call.
<i>eqlist</i>	specifies the list of equations to which the specifications in this %AR call are to be applied. Only names specified in the <i>endolist</i> value of the first call for the <i>name</i> value can appear in the list of equations in <i>eqlist</i> .
<i>varlist</i>	specifies the list of equations whose lagged structural residuals are to be included as regressors in the equations in <i>eqlist</i> . Only names in the <i>endolist</i> of the first call for the <i>name</i> value can appear in <i>varlist</i> . If not specified, <i>varlist</i> defaults to <i>endolist</i> .
<i>laglist</i>	specifies the list of lags at which the AR terms are to be added. The coefficients of the terms at lags not listed are set to 0. All of the listed lags must be less than or equal to the value of <i>nlag</i> , and there must be no duplicates. If not specified, <i>laglist</i> defaults to all lags 1 through <i>nlag</i> .

The %MA Macro

The SAS macro %MA generates programming statements for PROC MODEL for moving-average models. The %MA macro is part of SAS/ETS software, and no special options are needed to use the macro. The moving-average error process can be applied to the structural equation errors. The syntax of the %MA macro is the same as the %AR macro except there is no TYPE= argument.

When you are using the %MA and %AR macros combined, the %MA macro must follow the %AR macro. The following SAS/IML statements produce an ARMA(1, (1 3)) error process and save it in the data set MADAT2.

```
/* use IML module to simulate a MA process */
proc iml;
  phi = { 1 .2 };
  theta = { 1 .3 0 .5 };
  y = armasim( phi, theta, 0, .1, 200, 32565 );
  create madat2 from y[colname='y'];
  append from y;
quit;
```

The following PROC MODEL statements are used to estimate the parameters of this model by using maximum likelihood error structure:

```

title 'Maximum Likelihood ARMA(1, (1 3))';
proc model data=madat2;
  y=0;
  %ar( y, 1, , M=m1 )
  %ma( y, 3, , 1 3, M=m1 ) /* %MA always after %AR */
  fit y;
run;
title;

```

The estimates of the parameters produced by this run are shown in [Figure 18.61](#).

Figure 18.61 Estimates from an ARMA(1, (1 3)) Process

Maximum Likelihood ARMA(1, (1 3))							
The MODEL Procedure							
Nonlinear OLS Summary of Residual Errors							
Equation	DF Model	DF Error	SSE	MSE	Root MSE	R-Square	Adj R-Sq
y	3	197	2.6383	0.0134	0.1157	-0.0067	-0.0169
RESID.y		197	1.9957	0.0101	0.1007		
Nonlinear OLS Parameter Estimates							
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t	Label		
y_l1	-0.10067	0.1187	-0.85	0.3973	AR(y) y lag1 parameter		
y_m1	-0.1934	0.0939	-2.06	0.0408	MA(y) y lag1 parameter		
y_m3	-0.59384	0.0601	-9.88	<.0001	MA(y) y lag3 parameter		

Syntax of the %MA Macro

There are two cases of the syntax for the %MA macro. When restrictions on a vector MA process are not needed, the syntax of the %MA macro has the general form

```
%MA ( name , nlag < , endlolist < , laglist >> < , M= method > );
```

where

name specifies a prefix for %MA to use in constructing names of variables needed to define the MA process and is the default *endlolist*.

nlag is the order of the MA process.

<i>endolist</i>	specifies the equations to which the MA process is to be applied. If more than one name is given, CLS estimation is used for the vector process.
<i>laglist</i>	specifies the lags at which the MA terms are to be added. All of the listed lags must be less than or equal to <i>nlag</i> , and there must be no duplicates. If not specified, the <i>laglist</i> defaults to all lags 1 through <i>nlag</i> .
<i>M=method</i>	specifies the estimation method to implement. Valid values of <i>M=</i> are CLS (conditional least squares estimates), ULS (unconditional least squares estimates), and ML (maximum likelihood estimates). <i>M=CLS</i> is the default. Only <i>M=CLS</i> is allowed when more than one equation is specified in the <i>endolist</i> .

%MA Macro Syntax for Restricted Vector Moving-Average

An alternative use of `%MA` is allowed to impose restrictions on a vector MA process by calling `%MA` several times to specify different MA terms and lags for different equations.

The first call has the general form

```
%MA( name , nlag , endolist , DEFER ) ;
```

where

<i>name</i>	specifies a prefix for <code>%MA</code> to use in constructing names of variables needed to define the vector MA process.
<i>nlag</i>	specifies the order of the MA process.
<i>endolist</i>	specifies the list of equations to which the MA process is to be applied.
DEFER	specifies that <code>%MA</code> is not to generate the MA process but is to wait for further information specified in later <code>%MA</code> calls for the same <i>name</i> value.

The subsequent calls have the general form

```
%MA( name, eqlist, varlist, laglist )
```

where

<i>name</i>	is the same as in the first call.
<i>eqlist</i>	specifies the list of equations to which the specifications in this <code>%MA</code> call are to be applied.
<i>varlist</i>	specifies the list of equations whose lagged structural residuals are to be included as regressors in the equations in <i>eqlist</i> .
<i>laglist</i>	specifies the list of lags at which the MA terms are to be added.

Distributed Lag Models and the %PDL Macro

In the following example, the variable y is modeled as a linear function of x , the first lag of x , the second lag of x , and so forth:

$$y_t = a + b_0x_t + b_1x_{t-1} + b_2x_{t-2} + b_3x_{t-3} + \dots + b_nx_{t-n}$$

Models of this sort can introduce a great many parameters for the lags, and there may not be enough data to compute accurate independent estimates for them all. Often, the number of parameters is reduced by assuming that the lag coefficients follow some pattern. One common assumption is that the lag coefficients follow a polynomial in the lag length

$$b_i = \sum_{j=0}^d \alpha_j (i)^j$$

where d is the degree of the polynomial used. Models of this kind are called *Almon lag models*, *polynomial distributed lag models*, or *PDLs* for short. For example, Figure 18.62 shows the lag distribution that can be modeled with a low-order polynomial. Endpoint restrictions can be imposed on a PDL to require that the lag coefficients be 0 at the 0th lag, or at the final lag, or at both.

Figure 18.62 Polynomial Distributed Lags

For linear single-equation models, SAS/ETS software includes the PDLREG procedure for estimating PDL models. See Chapter 20, “[The PDLREG Procedure](#),” for a more detailed discussion of polynomial distributed lags and an explanation of endpoint restrictions.

Polynomial and other distributed lag models can be estimated and simulated or forecast with PROC MODEL. For polynomial distributed lags, the %PDL macro can generate the needed programming statements automatically.

The %PDL Macro

The SAS macro %PDL generates the programming statements to compute the lag coefficients of polynomial distributed lag models and to apply them to the lags of variables or expressions.

To use the %PDL macro in a model program, you first call it to declare the lag distribution; later, you call it again to apply the PDL to a variable or expression. The first call generates a PARMS statement for the polynomial parameters and assignment statements to compute the lag coefficients. The second call generates an expression that applies the lag coefficients to the lags of the specified variable or expression. A PDL can be declared only once, but it can be used any number of times (that is, the second call can be repeated).

The initial declaratory call has the general form

```
%PDL ( pdlname, nlags, degree , R=code , OUTEST=dataset ) ;
```

where *pdlname* is a name (up to 32 characters) that you give to identify the PDL, *nlags* is the lag length, and *degree* is the degree of the polynomial for the distribution. The *R=code* is optional for endpoint restrictions. The value of *code* can be FIRST (for upper), LAST (for lower), or BOTH (for both upper and lower endpoints). See Chapter 20, “The PDLREG Procedure,” for a discussion of endpoint restrictions. The option *OUTEST=dataset* creates a data set that contains the estimates of the parameters and their covariance matrix.

The later calls to apply the PDL have the general form

```
%PDL( pdlname, expression )
```

where *pdlname* is the name of the PDL and *expression* is the variable or expression to which the PDL is to be applied. The *pdlname* given must be the same as the name used to declare the PDL.

The following statements produce the output in [Figure 18.63](#):

```
proc model data=in list;
  parms int pz;
  %pdl(xpdl, 5, 2);
  y = int + pz * z + %pdl(xpdl, x);
  %ar(y, 2, M=ULS);
  id i;
  fit y / out=modell outresid converge=1e-6;
run;
```

Figure 18.63 %PDL Macro Estimates

The MODEL Procedure					
Nonlinear OLS Estimates					
Term	Estimate	Approx Std Err	t Value	Approx Pr > t	Label
XPDL_L0	1.568788	0.0935	16.77	<.0001	PDL(XPDL,5,2) coefficient for lag0
XPDL_L1	0.564917	0.0328	17.22	<.0001	PDL(XPDL,5,2) coefficient for lag1
XPDL_L2	-0.05063	0.0593	-0.85	0.4155	PDL(XPDL,5,2) coefficient for lag2
XPDL_L3	-0.27785	0.0517	-5.37	0.0004	PDL(XPDL,5,2) coefficient for lag3
XPDL_L4	-0.11675	0.0368	-3.17	0.0113	PDL(XPDL,5,2) coefficient for lag4
XPDL_L5	0.43267	0.1362	3.18	0.0113	PDL(XPDL,5,2) coefficient for lag5

This second example models two variables, Y1 and Y2, and uses two PDLs:

```
proc model data=in;
  parms int1 int2;
  %pdl( logxpdl, 5, 3 )
  %pdl( zpd1, 6, 4 )
  y1 = int1 + %pdl( logxpdl, log(x) ) + %pdl( zpd1, z );
  y2 = int2 + %pdl( zpd1, z );
  fit y1 y2;
run;
```

A (5,3) PDL of the log of X is used in the equation for Y1. A (6,4) PDL of Z is used in the equations for both Y1 and Y2. Since the same ZPDL is used in both equations, the lag coefficients for Z are the same for the Y1 and Y2 equations, and the polynomial parameters for ZPDL are shared by the two equations. See [Example 18.5](#) for a complete example and comparison with PDLREG.

Input Data Sets

DATA= Input Data Set

For FIT tasks, the DATA= option specifies which input data set to use in estimating parameters. Variables in the model program are looked up in the DATA= data set and, if found, their attributes (type, length, label, and format) are set to be the same as those in the DATA= data set (if not defined otherwise within PROC MODEL).

ESTDATA= Input Data Set

The ESTDATA= option specifies an input data set that contains an observation that gives values for some or all of the model parameters. The data set can also contain observations that give the rows of a covariance matrix for the parameters.

Parameter values read from the ESTDATA= data set provide initial starting values for parameters estimated. Observations that provide covariance values, if any are present in the ESTDATA= data set, are ignored.

The ESTDATA= data set is usually created by the OUTEST= option in a previous FIT statement. You can also create an ESTDATA= data set with a SAS DATA step program. The data set must contain a numeric variable for each parameter to be given a value or covariance column. The name of the variable in the ESTDATA= data set must match the name of the parameter in the model. Parameters with names longer than 32 characters cannot be set from an ESTDATA= data set. The data set must also contain a character variable `_NAME_` of length 32. `_NAME_` has a blank value for the observation that gives values to the parameters. `_NAME_` contains the name of a parameter for observations that define rows of the covariance matrix.

More than one set of parameter estimates and covariances can be stored in the ESTDATA= data set if the observations for the different estimates are identified by the variable `_TYPE_`. `_TYPE_` must be a character variable of length 8. The TYPE= option is used to select for input the part of the ESTDATA= data set for which the `_TYPE_` value matches the value of the TYPE= option.

In PROC MODEL, you have several options to specify starting values for the parameters to be estimated. When more than one option is specified, the options are implemented in the following order of precedence (from highest to lowest): the START= option, the PARMS statement initialization value, the ESTDATA= option, and the PARMSDATA= option. If no options are specified for the starting value, the default value of 0.0001 is used.

The following SAS statements generate the ESTDATA= data set shown in [Figure 18.64](#). The second FIT statement uses the TYPE= option to select the estimates from the GMM estimation as starting values for the FIML estimation.

```

/* Generate test data */
data gmm2;
  do t=1 to 50;
    x1 = sqrt(t) ;
    x2 = rannor(10) * 10;
    y1 = -.002 * x2 * x2 - .05 / x2 - 0.001 * x1 * x1;
    y2 = 0.002* y1 + 2 * x2 * x2 + 50 / x2 + 5 * rannor(1);
    y1 = y1 + 5 * rannor(1);
    z1 = 1; z2 = x1 * x1; z3 = x2 * x2; z4 = 1.0/x2;
    output;
  end;
run;

proc model data=gmm2 ;
  exogenous x1 x2;
  parms a1 a2 b1 2.5 b2 c2 55 d1;
  inst b1 b2 c2 x1 x2;
  y1 = a1 * y2 + b1 * x1 * x1 + d1;

```

```

y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2 + d1;

fit y1 y2 / 3sls gmm kernel=(qs,1,0.2) outest=gmmest;

fit y1 y2 / fiml type=gmm estdata=gmmest;
run;

proc print data=gmmest;
run;

```

2	GMM	0	Converged	50	-0.001772196	-1.02345	0.014025	1.99726	49.8648	-0.87573

MISSING=PAIRWISE | DELETE

When missing values are encountered for any one of the equations in a system of equations, the default action is to drop that observation for all of the equations. The new `MISSING=PAIRWISE` option in the `FIT` statement provides a different method of handling missing values that avoids losing data for nonmissing equations for the observation. This is especially useful for SUR estimation on equations with unequal numbers of observations.

The option `MISSING=PAIRWISE` specifies that missing values are tracked on an equation-by-equation basis. The `MISSING=DELETE` option specifies that the entire observation is omitted from the analysis when any equation has a missing predicted or actual value for the equation. The default is `MISSING=DELETE`.

When you specify the `MISSING=PAIRWISE` option, the **S** matrix is computed as

$$\mathbf{S} = \mathbf{D}(\mathbf{R}'\mathbf{R})\mathbf{D}$$

where **D** is a diagonal matrix that depends on the `VARDEF=` option, the matrix **R** is $(\mathbf{r}_1, \dots, \mathbf{r}_g)$, and \mathbf{r}_i is the vector of residuals for the *i*th equation with r_{ij} replaced with zero when r_{ij} is missing.

For `MISSING=PAIRWISE`, the calculation of the diagonal element $d_{i,j}$ of **D** is based on n_i , the number of nonmissing observations for the *i*th equation, instead of on n . Similarly, for `VARDEF=WGT` or `WDF`, the calculation is based on the sum of the weights for the nonmissing observations for the *i*th equation instead of on the sum of the weights for all observations. See the description of the `VARDEF=` option for the definition of **D**.

The degrees-of-freedom correction for a shared parameter is computed by using the average number of observations used in its estimation.

The MISSING=PAIRWISE option is not valid for the GMM and FIML estimation methods.

For the instrumental variables estimation methods (2SLS, 3SLS), when an instrument is missing for an observation, that observation is dropped for all equations, regardless of the MISSING= option.

PARMSDATA= Input Data Set

The option PARMSDATA= reads values for all parameters whose names match the names of variables in the PARMSDATA= data set. Values for any or all of the parameters in the model can be reset by using the PARMSDATA= option. The PARMSDATA= option goes in the PROC MODEL statement, and the data set is read before any FIT or SOLVE statements are executed.

In PROC MODEL, you have several options to specify starting values for the parameters to be estimated. When more than one option is specified, the options are implemented in the following order of precedence (from highest to lowest): the START= option, the PARMS statement initialization value, the ESTDATA= option, and the PARMSDATA= option. If no options are specified for the starting value, the default value of 0.0001 is used.

Together, the OUTPARMS= and PARMSDATA= options enable you to change part of a model and recompile the new model program without the need to reestimate equations that were not changed.

Suppose you have a large model with parameters estimated and you now want to replace one equation, Y, with a new specification. Although the model program must be recompiled with the new equation, you don't need to reestimate all the equations, just the one that changed.

Using the OUTPARMS= and PARMSDATA= options, you could do the following:

```
proc model model=oldmod outparms=temp; run;
proc model outmodel=newmod parmsdata=temp data=in;
    ... include new model definition with changed y eq. here ...
    fit y;
run;
```

The model file NEWMOD then contains the new model and its estimated parameters plus the old models with their original parameter values.

SDATA= Input Data Set

The SDATA= option allows a cross-equation covariance matrix to be input from a data set. The **S** matrix read from the SDATA= data set, specified in the FIT statement, is used to define the objective function for the OLS, N2SLS, SUR, and N3SLS estimation methods and is used as the initial **S** for the methods that iterate the **S** matrix.

Most often, the SDATA= data set has been created by the OUTS= or OUTSUSED= option in a previous FIT statement. The OUTS= and OUTSUSED= data sets from a FIT statement can be read back in by a FIT statement in the same PROC MODEL step.

You can create an input SDATA= data set by using the DATA step. PROC MODEL expects to find a character variable `_NAME_` in the SDATA= data set as well as variables for the equations in the

estimation or solution. For each observation with a `_NAME_` value that matches the name of an equation, PROC MODEL fills the corresponding row of the **S** matrix with the values of the names of equations found in the data set. If a row or column is omitted from the data set, a 1 is placed on the diagonal for the row or column. Missing values are ignored, and since the **S** matrix is symmetric, you can include only a triangular part of the **S** matrix in the `SDATA=` data set with the omitted part indicated by missing values. If the `SDATA=` data set contains multiple observations with the same `_NAME_`, the last values supplied for the `_NAME_` are used. The structure of the expected data set is further described in the section “[OUTS= Data Set](#)” on page 1162.

Use the `TYPE=` option in the PROC MODEL or FIT statement to specify the type of estimation method used to produce the **S** matrix you want to input.

The following SAS statements are used to generate an **S** matrix from a GMM and a 3SLS estimation and to store that estimate in the data set GMMS:

```
proc model data=gmm2 ;
  exogenous x1 x2;
  parms a1 a2 b1 2.5 b2 c2 55 d1;
  inst b1 b2 c2 x1 x2;
  y1 = a1 * y2 + b1 * x1 * x1 + d1;
  y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2 + d1;

  fit y1 y2 / 3s1s gmm kernel=(qs,1,0.2)
             outest=gmmest outs=gmms;
run;

proc print data=gmms;
run;
```

The data set GMMS is shown in [Figure 18.65](#).

Figure 18.65 `SDATA=` Data Set

Obs	<code>_NAME_</code>	<code>_TYPE_</code>	<code>_NUSED_</code>	y1	y2
1	y1	3SLS	50	27.1032	38.1599
2	y2	3SLS	50	38.1599	74.6253
3	y1	GMM	50	27.6248	32.2811
4	y2	GMM	50	32.2811	58.8387

VDATA= Input data set

The `VDATA=` option enables a variance matrix for GMM estimation to be input from a data set. When the `VDATA=` option is used in the PROC MODEL or FIT statement, the matrix that is input is used to define the objective function and is used as the initial **V** for the methods that iterate the **V** matrix.

Normally the `VDATA=` matrix is created from the `OUTV=` option in a previous FIT statement. Alternately an input `VDATA=` data set can be created by using the `DATA` step. Each row and column of the **V** matrix is associated with an equation and an instrument. The position of each element in the **V** matrix can then be indicated by an equation name and an instrument name for the row of the

element and an equation name and an instrument name for the column. Each observation in the VDATA= data set is an element in the **V** matrix. The row and column of the element are indicated by four variables (EQ_ROW, INST_ROW, EQ_COL, and INST_COL) that contain the equation name or instrument name. The variable name for an element is VALUE. Missing values are set to 0. Because the variance matrix is symmetric, only a triangular part of the matrix needs to be input.

The following SAS statements are used to generate a **V** matrix estimation from GMM and to store that estimate in the data set GMMV:

```
proc model data=gmm2;
  exogenous x1 x2;
  parms a1 a2 b2 b1 2.5 c2 55 d1;
  inst b1 b2 c2 x1 x2;
  y1 = a1 * y2 + b1 * x1 * x1 + d1;
  y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2 + d1;

  fit y1 y2 / gmm outv=gmmv;
run;

proc print data=gmmv(obs=15);
run;
```

The data set GMM2 was generated by the example in the preceding ESTDATA= section. The **V** matrix stored in GMMV is selected for use in an additional GMM estimation by the following FIT statement:

```
fit y1 y2 / gmm vdata=gmmv;
run;
```

A partial listing of the GMMV data set is shown in [Figure 18.66](#). There are a total of 78 observations in this data set. The **V** matrix is 12 by 12 for this example.

Figure 18.66 The First 15 Observations in the VDATA= Data Set

Obs	_TYPE_	EQ_ROW	EQ_COL	INST_ROW	INST_COL	VALUE

Output Data Sets

OUT= Data Set

For normalized form equations, the OUT= data set specified in the FIT statement contains residuals, actuals, and predicted values of the dependent variables computed from the parameter estimates. For general form equations, actual values of the endogenous variables are copied for the residual and predicted values.

The variables in the data set are as follows:

- BY variables
- RANGE variable
- ID variables
- `_ESTYPE_`, a character variable of length 8 that identifies the estimation method: OLS, SUR, N2SLS, N3SLS, ITOLS, ITSUR, IT2SLS, IT3SLS, GMM, ITGMM, or FIML
- `_TYPE_`, a character variable of length 8 that identifies the type of observation: RESIDUAL, PREDICT, or ACTUAL
- `_WEIGHT_`, the weight of the observation in the estimation. The `_WEIGHT_` value is 0 if the observation was not used. It is equal to the product of the `_WEIGHT_` model program variable and the variable named in the WEIGHT statement, if any, or 1 if weights were not used.
- the WEIGHT statement variable if used
- the model variables. The dependent variables for the normalized form equations in the estimation contain residuals, actuals, or predicted values, depending on the `_TYPE_` variable, whereas the model variables that are not associated with estimated equations always contain actual values from the input data set.
- any other variables named in the OUTVARS statement. These can be program variables computed by the model program, CONTROL variables, parameters, or special variables in the model program.

The following SAS statements are used to generate and print an OUT= data set:

```
proc model data=gmm2;
  exogenous x1 x2;
  parms a1 a2 b2 b1 2.5 c2 55 d1;
  inst b1 b2 c2 x1 x2;
  y1 = a1 * y2 + b1 * x1 * x1 + d1;
  y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2 + d1;

  fit y1 y2 / 3sls gmm out=resid outall ;
run;
```

```
proc print data=resid(obs=20);
run;
```

The data set GMM2 was generated by the example in the preceding ESTDATA= section above. A partial listing of the RESID data set is shown in [Figure 18.67](#).

OUTEST= Data Set

The OUTEST= data set contains parameter estimates and, if requested, estimates of the covariance of the parameter estimates.

The variables in the data set are as follows:

- BY variables
- NAME, a character variable of length 32, blank for observations that contain parameter estimates or a parameter name for observations that contain covariances
- TYPE, a character variable of length 8 that identifies the estimation method: OLS, SUR, N2SLS, N3SLS, ITOLS, ITSUR, IT2SLS, IT3SLS, GMM, ITGMM, or FIML
- STATUS, variable that gives the convergence status of estimation. STATUS = 0 when convergence criteria are met, = 1 when estimation converges with a note, = 2 when estimation converges with a warning, and = 3 when estimation fails to converge
- NUSED, the number of observations used in estimation

- the parameters estimated

If the COVOUT option is specified, an additional observation is written for each row of the estimate of the covariance matrix of parameter estimates, with the `_NAME_` values that contain the parameter names for the rows. Parameter names longer than 32 characters are truncated.

OUTPARMS= Data Set

The option `OUTPARMS=` writes all the parameter estimates to an output data set. This output data set contains one observation and is similar to the `OUTEST=` data set, but it contains all the parameters, is not associated with any FIT task, and contains no covariances. The `OUTPARMS=` option is used in the PROC MODEL statement, and the data set is written at the end, after any FIT or SOLVE steps have been performed.

OUTS= Data Set

The `OUTS=` SAS data set contains the estimate of the covariance matrix of the residuals across equations. This matrix is formed from the residuals that are computed by using the parameter estimates.

The variables in the `OUTS=` data set are as follows:

- BY variables
- `_NAME_`, a character variable that contains the name of the equation
- `_TYPE_`, a character variable of length 8 that identifies the estimation method: OLS, SUR, N2SLS, N3SLS, ITOLS, ITSUR, IT2SLS, IT3SLS, GMM, ITGMM, or FIML
- variables with the names of the equations in the estimation

Each observation contains a row of the covariance matrix. The data set is suitable for use with the `SDATA=` option in a subsequent FIT or SOLVE statement. (See the section “Tests on Parameters” on page 1128 in this chapter for an example of the `SDATA=` option.)

OUTSUSED= Data Set

The `OUTSUSED=` SAS data set contains the covariance matrix of the residuals across equations that is used to define the objective function. The form of the `OUTSUSED=` data set is the same as that for the `OUTS=` data set.

Note that `OUTSUSED=` is the same as `OUTS=` for the estimation methods that iterate the **S** matrix (ITOLS, IT2SLS, ITSUR, and IT3SLS). If the `SDATA=` option is specified in the FIT statement, `OUTSUSED=` is the same as the `SDATA=` matrix read in for the methods that do not iterate the **S** matrix (OLS, SUR, N2SLS, and N3SLS).

OUTV= Data Set

The OUTV= data set contains the estimate of the variance matrix, V . This matrix is formed from the instruments and the residuals that are computed by using the final parameter estimates obtained from the estimation method chosen.

An estimate of V obtained from 2SLS is used in GMM estimation. Hence if you input the dataset obtained from the OUTV statement in 2SLS into the VDATA statement while fitting GMM, you get the same result by fitting GMM directly without specifying the VDATA option.

ODS Table Names

PROC MODEL assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 18.4 ODS Tables Produced in PROC MODEL

ODS Table Name	Description	Option
ODS Tables Created by the FIT Statement		
AugGMMCovariance	Crossproducts matrix	GMM ITALL
ChowTest	Structural change test	CHOW=
CollinDiagnostics	Collinearity diagnostics	
ConfInterval	Profile likelihood confidence intervals	PRL=
ConvCrit	Convergence criteria for estimation	default
ConvergenceStatus	Convergence status	default
CorrB	Correlations of parameters	COVB/CORRB
CorrResiduals	Correlations of residuals	CORRS/COVS
CovB	Covariance of parameters	COVB/CORRB
CovResiduals	Covariance of residuals	CORRS/COVS
Crossproducts	Crossproducts matrix	ITALL/ITPRINT
DatasetOptions	Data sets used	default
DetResidCov	Determinant of the residuals	DETAILS
DWTest	Durbin Watson test	DW=
Equations	Listing of equations to estimate	default
EstSummaryMiss	Model summary statistics for PAIRWISE	MISSING=
EstSummaryStats	Objective, objective * N	default
FirstLagrMultEst	First order Lagrange Multiplier estimates	GMM ITALL
GMMCovariance	Crossproducts matrix	GMM DETAILS
GMMTestStats	GMM test statistics	GMM
Godfrey	Godfrey's serial correlation test	GF=
HausmanTest	Hausman's test table	HAUSMAN
HeteroTest	Heteroscedasticity test tables	BREUSCH/PAGEN
InvXPXMat	X'X inverse for system	I

Table 18.4 (continued)

ODS Table Name	Description	Option
IterInfo	Iteration printing	ITALL/ITPRINT
LagLength	Model lag length	default
MinSummary	Number of parameters, estimation kind	default
ModSummary	Listing of all categorized variables	default
ModVars	Listing of model variables and parameters	default
NormalityTest	Normality test table	NORMAL
ObsSummary	Identifies observations with errors	default
ObsUsed	Observations read, used, and missing.	default
ParameterEstimates	Parameter estimates	default
ParmChange	Parameter change vector	ITALL
ResidSummary	Summary of the SSE, MSE for the equations	default
SecondLagrMultEst	Second order Lagrange Multiplier estimates	GMM ITALL
SizeInfo	Storage requirement for estimation	DETAILS
TermEstimates	Nonlinear OLS and ITOLS Estimates	OLS/ITOLS
TestResults	Test statement table	
WgtVar	The name of the weight variable	
XPXMat	$X'X$ for system	XPX
YkVector	Marquardt iteration vector	GMM ITALL

ODS Tables Created by the SOLVE Statement

TransitiveClosure	Transitive closure graph	GRAPH

The AugGMMCOvariance table is the \mathbf{V} matrix augmented with the moment vector at iteration zero, produced when the ITALL option is used with the GMM option. If the \mathbf{V} matrix to be used in GMM is read in by the VDATA option, then AugGMMCOvariance would be the same matrix augmented with the moment vectors. The GMMCOvariance ODS output is produced only when you read in a covariance matrix to be used in the GMM method. This table is produced by using DETAILS option with the GMM option.

ODS Graphics

This section describes the use of ODS for creating graphics with the MODEL procedure.

ODS Graph Names

PROC MODEL assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when you use ODS. The names are listed in Table 18.5.

To request these graphs, you must specify the ODS GRAPHICS statement.

Table 18.5 ODS Graphics Produced by PROC MODEL

ODS Graph Name	Plot Description
ACFPlot	Autocorrelation of residuals
ActualByPredicted	Predicted versus actual plot
CooksD	Cook's D plot
IACFPlot	Inverse autocorrelation of residuals
QQPlot	Q-Q plot of residuals
PACFPlot	Partial autocorrelation of residuals
ResidualHistogram	Histogram of the residuals
StudentResidualPlot	Studentized residual plot

Details: Simulation by the MODEL Procedure

The *solution*, given the vector \mathbf{k} , of the following nonlinear system of equations is the vector \mathbf{u} that satisfies this equation:

$$\mathbf{q}(\mathbf{u}, \mathbf{k}, \boldsymbol{\theta}) = 0$$

A *simulation* is a set of solutions \mathbf{u}_t for a specific sequence of vectors \mathbf{k}_t .

Model simulation can be performed to do the following:

- check how well the model predicts the actual values over the historical period
- investigate the sensitivity of the solution to changes in the input values or parameters
- examine the dynamic characteristics of the model
- check the stability of the simultaneous solution
- estimate the statistical distribution of the predicted values of the nonlinear model using Monte Carlo methods

By combining the various solution modes with different input data sets, model simulation can answer many different questions about the model. This section presents details of model simulation and solution.

Solution Modes

The following solution modes are commonly used:

- The *dynamic simultaneous forecast* mode is used for forecasting with the model. Collect the historical data on the model variables, the future assumptions of the exogenous variables, and any prior information on the future endogenous values, and combine them in a SAS data set. Use the FORECAST option in the SOLVE statement.
- The *dynamic simultaneous simulation* mode is often called *ex post simulation*, *historical simulation*, or *ex post forecasting*. Use the DYNAMIC option. This mode is the default.
- The *static simultaneous simulation* mode can be used to examine the within-period performance of the model without the complications of previous period errors. Use the STATIC option.
- The *NAHEAD=n dynamic simultaneous simulation* mode can be used to see how well *n*-period-ahead forecasting would have performed over the historical period. Use the NAHEAD=*n* option.

The different solution modes are explained in detail in the following sections.

Dynamic and Static Simulations

In model simulation, either solved values or actual values from the data set can be used to supply lagged values of an endogenous variable. A *dynamic* solution refers to a solution obtained by using only solved values for the lagged values. Dynamic mode is used both for forecasting and for simulating the dynamic properties of the model.

A *static* solution refers to a solution obtained by using the actual values when available for the lagged endogenous values. Static mode is used to simulate the behavior of the model without the complication of previous period errors. Dynamic simulation is the default.

If you want to use static values for lags only for the first n observations, and dynamic values thereafter, specify the `START= n` option. For example, if you want a dynamic simulation to start after observation twenty-four, specify `START=24` on the `SOLVE` statement. If the model being simulated had a value lagged for four time periods, then this value would start using dynamic values when the simulation reached observation number 28.

n -Period-Ahead Forecasting

Suppose you want to regularly forecast 12 months ahead and produce a new forecast each month as more data becomes available. n -period-ahead forecasting allows you to test how well you would have done over time if you had been using your model to forecast one year ahead.

To see how well a model predicts n time periods in the future, perform an n -period-ahead forecast on real data and compare the forecast values with the actual values.

n -period-ahead forecasting refers to using dynamic values for the lagged endogenous variables only for lags 1 through $n-1$. For example, one-period-ahead forecasting, specified by the `NAHEAD=1` option in the `SOLVE` statement, is the same as if a static solution had been requested. Specifying `NAHEAD=2` produces a solution that uses dynamic values for lag one and static, actual, values for longer lags.

The following example is a two-year-ahead dynamic simulation. The output is shown in [Figure 18.68](#).

```
data yearly;
  input year x1 x2 x3 y1 y2 y3;
  datalines;
84 4 9 0 7 4 5
85 5 6 1 1 27 4
86 3 8 2 5 8 2
87 2 10 3 0 10 10
88 4 7 6 20 60 40
89 5 4 8 40 40 40
90 3 2 10 50 60 60
91 2 5 11 40 50 60
;
run;

proc model data=yearly outmodel=yearlyModel;
  endogenous y1 y2 y3;
  exogenous x1 x2 x3;
```

```

y1 = 2 + 3*x1 - 2*x2 + 4*x3;
y2 = 4 + lag2( y3 ) + 2*y1 + x1;
y3 = lag3( y1 ) + y2 - x2;

solve y1 y2 y3 / nahead=2 out=c;
run;

proc print data=c;
run;

```

Figure 18.68 NAHEAD Summary Report

The MODEL Procedure	
Dynamic Simultaneous 2-Periods-Ahead Forecasting Simulation	
Data Set Options	
DATA=	YEARLY
OUT=	C

Solution Method	NEWTON
CONVERGE=	1E-8
Maximum CC	0
Maximum Iterations	1
Total Iterations	8
Average Iterations	1
Observations Processed	
Read	20
Lagged	12
Solved	8
First	5
Last	8
Variables Solved For	y1 y2 y3

The C data set is shown in [Figure 18.69](#):

Figure 18.69 C Data Set

Obs	_TYPE_	_MODE_	_LAG_	_ERRORS_	y1	y2	y3	x1	x2	x3
1	PREDICT	SIMULATE	0	0	0	10	7	2	10	3
2	PREDICT	SIMULATE	1	0	24	58	52	4	7	6
3	PREDICT	SIMULATE	1	0	41	101	102	5	4	8
4	PREDICT	SIMULATE	1	0	47	141	139	3	2	10
5	PREDICT	SIMULATE	1	0	42	130	145	2	5	11

The preceding two-year-ahead simulation can be emulated without using the NAHEAD= option by the following PROC MODEL statements:

```
proc model data=yearly model=yearlyModel;
  range year = 87 to 88;
  solve y1 y2 y3 / dynamic solveprint;
run;

  range year = 88 to 89;
  solve y1 y2 y3 / dynamic solveprint;
run;

  range year = 89 to 90;
  solve y1 y2 y3 / dynamic solveprint;
run;

  range year = 90 to 91;
  solve y1 y2 y3 / dynamic solveprint;
```

The totals shown under “Observations Processed” in [Figure 18.68](#) are equal to the sum of the four individual runs.

Simulation and Forecasting

You can perform a simulation of your model or use the model to produce forecasts. *Simulation* refers to the determination of the endogenous or dependent variables as a function of the input values of the other variables, even when actual data for some of the solution variables are available in the input data set. The simulation mode is useful for verifying the fit of the model parameters. Simulation is selected by the SIMULATE option in the SOLVE statement. Simulation mode is the default.

In forecast mode, PROC MODEL solves only for those endogenous variables that are missing in the data set. The actual value of an endogenous variable is used as the solution value whenever nonmissing data for it is available in the input data set. Forecasting is selected by the FORECAST option in the SOLVE statement.

For example, an econometric forecasting model can contain an equation to predict future tax rates, but tax rates are usually set in advance by law. Thus, for the first year or so of the forecast, the predicted tax rate should really be exogenous. Or, you might want to use a prior forecast of a certain variable from a short-run forecasting model to provide the predicted values for the earlier periods of a longer-range forecast of a long-run model. A common situation in forecasting is when historical data needed to fill the initial lags of a dynamic model are available for some of the variables but have not yet been obtained for others. In this case, the forecast must start in the past to supply the missing initial lags. Clearly, you should use the actual data that are available for the lags. In all the preceding cases, the forecast should be produced by running the model in the FORECAST mode; simulating the model over the future periods would not be appropriate.

Monte Carlo Simulation

The accuracy of the forecasts produced by PROC MODEL depends on four sources of error (Pindyck and Rubinfeld 1981, 405–406):

- The system of equations contains an implicit random error term ϵ

$$\mathbf{g}(\mathbf{y}, \mathbf{x}, \hat{\boldsymbol{\theta}}) = \boldsymbol{\epsilon}$$

where \mathbf{y} , \mathbf{x} , \mathbf{g} , $\hat{\boldsymbol{\theta}}$, and $\boldsymbol{\epsilon}$ are vector valued.

- The estimated values of the parameters, $\hat{\boldsymbol{\theta}}$, are themselves random variables.
- The exogenous variables might have been forecast themselves and therefore might contain errors.
- The system of equations might be incorrectly specified; the model only approximates the process modeled.

The RANDOM= option is used to request Monte Carlo (or stochastic) simulations to generate confidence intervals for errors that arise from the first two sources. The Monte Carlo simulations can be performed with $\boldsymbol{\epsilon}$, $\boldsymbol{\theta}$, or both vectors represented as random variables. The SEED= option is used to control the random number generator for the simulations. SEED=0 forces the random number generator to use the system clock as its seed value.

In Monte Carlo simulations, repeated simulations are performed on the model for random perturbations of the parameters and the additive error term. The random perturbations follow a multivariate normal distribution with expected value of 0 and covariance described by a covariance matrix of the parameter estimates in the case of $\boldsymbol{\theta}$, or a covariance matrix of the equation residuals for the case of $\boldsymbol{\epsilon}$. PROC MODEL can generate both covariance matrices or you can provide them.

The ESTDATA= option specifies a data set that contains an estimate of the covariance matrix of the parameter estimates to use for computing perturbations of the parameters. The ESTDATA= data set is usually created by the FIT statement with the OUTEST= and OUTCOV options. When the ESTDATA= option is specified, the matrix read from the ESTDATA= data set is used to compute vectors of random shocks or perturbations for the parameters. These random perturbations are computed at the start of each repetition of the solution and added to the parameter values. The perturbed parameters are fixed throughout the solution range. If the covariance matrix of the parameter estimates is not provided, the parameters are not perturbed.

The SDATA= option specifies a data set that contains the covariance matrix of the residuals to use for computing perturbations of the equations. The SDATA= data set is usually created by the FIT statement with the OUTS= option. When SDATA= is specified, the matrix read from the SDATA= data set is used to compute vectors of random shocks or perturbations for the equations. These random perturbations are computed at each observation. The simultaneous solution satisfies the model equations plus the random shocks. That is, the solution is not a perturbation of a simultaneous solution of the structural equations; rather, it is a simultaneous solution of the stochastic equations by using the simulated errors. If the SDATA= option is not specified, the random shocks are not used.

The different random solutions are identified by the `_REP_` variable in the `OUT=` data set. An unperturbed solution with `_REP_=0` is also computed when the `RANDOM=` option is used. `RANDOM= n` produces $n + 1$ solution observations for each input observation in the solution range. If the `RANDOM=` option is not specified, the `SDATA=` and `ESTDATA=` options are ignored, and no Monte Carlo simulation is performed.

`PROC MODEL` does not have an automatic way of modeling the exogenous variables as random variables for Monte Carlo simulation. If the exogenous variables have been forecast, the error bounds for these variables should be included in the error bounds generated for the endogenous variables. If the models for the exogenous variables are included in `PROC MODEL`, then the error bounds created from a Monte Carlo simulation contain the uncertainty due to the exogenous variables.

Alternatively, if the distribution of the exogenous variables is known, the built-in random number generator functions can be used to perturb these variables appropriately for the Monte Carlo simulation. For example, if you know the forecast of an exogenous variable, X , has a standard error of 5.2 and the error is normally distributed, then the following statements can be used to generate random values for X :

```
x_new = x + 5.2 * rannor(456);
```

During a Monte Carlo simulation, the random number generator functions produce one value at each observation. It is important to use a different seed value for all the random number generator functions in the model program; otherwise, the perturbations will be correlated. For the unperturbed solution, `_REP_=0`, the random number generator functions return 0.

`PROC UNIVARIATE` can be used to create confidence intervals for the simulation (see the Monte Carlo simulation example in the section “Getting Started: `MODEL` Procedure” on page 999).

Multivariate t Distribution Simulation

To perform a Monte Carlo analysis of models that have residuals distributed as a multivariate t , use the `ERRORMODEL` statement with either the `~ t(variance, df)` option or with the `CDF=t(variance, df)` option. The `CDF=` option specifies the distribution that is used for simulation so that the estimation can be done for one set of distributional assumptions and the simulation for another.

The following is an example of estimating and simulating a system of equations with t distributed errors by using the `ERRORMODEL` statement.

```
/* generate simulation data set */
data five;
  set xfrate end=last;
  if last then do;
    todate = date +5;
    do date = date to todate;
      output;
    end;
  end;
run;
```

The preceding DATA step generates the data set to request a five-days-ahead forecast. The following statements estimate and forecast the three forward-rate models of the following form.

$$\begin{aligned} \text{rate}_t &= \text{rate}_{t-1} + \mu * \text{rate}_{t-1} + v \\ v &= \sigma * \text{rate}_{t-1} * \epsilon \\ \epsilon &\sim N(0, 1) \end{aligned}$$

```

title "Daily Multivariate Geometric Brownian Motion Model "

run;

  /* forecast five days in advance */
  solve demusd1m demusd3m demusd6m /
    data=five sdata=s random=1500 out=monte;
  id date;
run;

  /* select out the last date ---*/
  data monte; set monte;
  if date = '10dec95'd then output;
run;

title "Distribution of demusd1m Five Days Ahead";
proc univariate data=monte noprint;
  var demusd1m;
  histogram demusd1m /
    normal(noprint color=red)
    kernel(noprint color=blue) cfill=ligr;
run;

```

The Monte Carlo simulation specified in the preceding example draws from a multivariate t distribution with constant degrees of freedom and forecasted variance, and it computes future states of DEMUSD1M, DEMUSD3M, and DEMUSD6M. The OUTSN= option in the FIT statement is used to specify the data set for the normalized Σ matrix. That is, the Σ matrix is created by crossing the

normally distributed residuals. The normally distributed residuals are created from the t distributed residuals by using the normal inverse CDF and the t CDF. This matrix is a correlation matrix.

The distribution of DEMUSD1M on the fifth day is shown in the Figure 18.70. The two curves overlaid on the graph are a kernel density estimation and a normal distribution fit to the results.

Figure 18.70 Distribution of DEMUSD1M

Alternate Distribution Simulation

As an alternate to the normal distribution, the `ERRORMODEL` statement can be used in a simulation to specify other distributions. The distributions available for simulation are Cauchy, chi-squared, F , Poisson, t , and uniform. An empirical distribution can also be used if the residuals are specified by using the `RESIDDATA=` option in the `SOLVE` statement.

Except for the t distribution, all of these alternate distributions are univariate but can be used together in a multivariate simulation. The `ERRORMODEL` statement applies to solved for equations only. That is, the normal form or general form equation referred to by the `ERRORMODEL` statement must be one of the equations you have selected in the `SOLVE` statement.

In the following example, two Poisson distributed variables are used to simulate the calls that arrive at and leave a call center.

```
data s;    /* Covariance between arriving and leaving */
  arriving = 1; leaving = 0.7; _name_ = "arriving";
  output;
  arriving = 0.7; leaving = 1.0; _name_ = "leaving";
  output;
run;

data calls;
  date = '20mar2001'd;
  output;
run;
```

The first DATA step generates a data set that contains a covariance matrix for the ARRIVING and LEAVING variables. The covariance is

$$\begin{vmatrix} 1 & .7 \\ .7 & 1 \end{vmatrix}$$

The following statements create the number of waiting clients data:

```
proc model data=calls;
  arriving = 0;
  errormodel arriving ~ poisson( 10 );
  leaving = 4;
  errormodel leaving ~ poisson( 11 );

  waiting = arriving - leaving;
  if waiting < 0 then waiting=0;
  outvars waiting;

  solve arriving leaving / random=500 sdata=s out=sim;
run;

title "Distribution of Clients Waiting";
proc univariate data=sim noprint;
  var waiting ;
  histogram waiting / cfill=ligr;
run;
```

The distribution of number of waiting clients is shown in [Figure 18.71](#).

Figure 18.71 Distribution of Number of Clients Waiting

Mixtures of Distributions—Copulas

The theory of copulas is what enables the MODEL procedure to combine and simulate multivariate distributions with different marginals. This section provides a brief overview of copulas.

Modeling a system of variables accurately is a difficult task. The underlying, ideal, distributional assumptions for each variable are usually different from each other. An individual variable might be best modeled as a t distribution or as a Poisson process. The correlation of the various variables are very important to estimate as well. A joint estimation of a set of variables would make it possible to estimate a correlation structure but would restrict the modeling to single, simple multivariate distribution (for example, the normal). Even with a simple multivariate distribution, the joint estimation would be computationally difficult and would have to deal with issues of missing data.

By using the MODEL procedure ERRORMODEL statement, you can combine and simulate from models of different distributions. The covariance matrix for the combined model is constructed by using the copula induced by the multivariate normal distribution. A copula is a function that couples joint distributions to their marginal distributions.

By default, the copula used in the MODEL procedure is based on the multivariate normal. This particular multivariate normal has zero mean and covariance matrix \mathbf{R} . The user provides \mathbf{R} , which can be created by using the following steps:

1. Each model is estimated separately and their residuals are saved.
2. The residuals for each model are converted to a normal distribution by using their CDFs, $F_i(\cdot)$, using the relationship $\Phi^{-1}(F(\epsilon_{it}))$.
3. These normal residuals are crossed to create a covariance matrix \mathbf{R} .

If the model of interest can be estimated jointly, such as multivariate T, then the OUTSN= option can be used to generate the correct covariance matrix.

A draw from this mixture of distributions is created by using the following steps that are performed automatically by the MODEL procedure.

1. Independent $N(0, 1)$ variables are generated.
2. These variables are transformed to a correlated set by using the covariance matrix \mathbf{R} .
3. These correlated normals are transformed to a uniform by using $\Phi(\cdot)$.
4. $F^{-1}(\cdot)$ is used to compute the final sample value.

Alternate Copulas

The Gaussian, t , and the normal mixture copula are available in the MODEL procedure. These copulas support asymmetric parameters and can use alternate estimation methods for creating the base covariance matrix.

The normal (Gaussian) copula is the default. A draw from a Gaussian copula is obtained from

$$\mathbf{x} = \mathbf{A}\mathbf{z}$$

where $\mathbf{z} \in R^d$ is a vector of independent random normal(0, 1) draws, $\mathbf{A} \in R^{d \times d}$ is the square root of the covariance matrix, \mathbf{R} . For the normal mixture and t copula, a draw is created as

$$\mathbf{x} = w\boldsymbol{\gamma} + \sqrt{w}\mathbf{A}\mathbf{z}$$

where w is a scalar random variable and $\boldsymbol{\gamma} \in R^d$ is a vector of asymmetry parameters. $\boldsymbol{\gamma}$ is specified in the SDATA= data set. If $W \sim$ inverse gamma($df/2, df/2$), then \mathbf{x} is multivariate t or skewed t if $\boldsymbol{\gamma}$ is provided. When NORMALMIX is specified, w is distributed as a step function with each of the n positive variances, $v_1 \dots v_n$, having probability $p_1 \dots p_n$.

The covariance matrix $\mathbf{R} = \mathbf{A}'\mathbf{A}$ is specified with the SDATA= option. The vector of asymmetry parameters, $\boldsymbol{\gamma}$, defaults to zero or is specified in the SDATA= data set with _TYPE_=ASYM. The ASYM option specifies that the nonzero asymmetry vector, $\boldsymbol{\gamma}$, is to be used.

The actual draw for an individual variable, y_i , depends on the marginal distribution of the variable, \tilde{F} , and the chosen copula F as

$$y_i = \tilde{F}_i^{-1}(F(x_i))$$

Asymmetrical Copula Example

In this example, an asymmetrical t copula is used to correlate two uniform distributions. The asymmetrical parameter is varied over a range of values to demonstrate its effect. The resulting graphs is produced by using ODS graphics.

```

data histdata;
  do asym = -1.3 to 1.1 by .3;
    date='01aug2007'd;
    y = .5;
    z = .5;
    output;
  end;
run ;

/* Add the asymmetric parameter to cov mat */
data asym;
  do asym = -1.3 to 1.1 by .3;
    y = asym;
    z = 0;
    _name_ = " ";
    _type_ = "asym";
    output;
    y = 1;
    z = .65;
    _name_ = "y";
    _type_ = "cov";
    output;
    y = .65;
    z = 1;
    _name_ = "z";
    _type_ = "cov";
    output;
  end;
run;

proc model out=sim(where=( _REP_ > 0)) data=histdata sdata=asym;
  y = 0;
  errormodel y ~ Uniform(0,1);

  z = 0;
  errormodel z ~ Uniform(0,1);

  solve y z / random=500 seed=12345 copula=(t(5) asym );
  by asym;
run;

```

To produce a panel plot of this joint distribution, use the following SAS/GRAPH statements.

```

ods graphics on / height=800 width=800;
proc template;
  define statgraph myplot.panel;
  BeginGraph;

```

```

entrytitle halign=left halign=center
      textattrs=GRAPHTITLETEXT "t Copula with a Range of Asymmetry";

layout datapanel classvars=(asym) / rows=3 columns=3
      order=rowmajor height=1024 width=1420
      rowaxisopts=(griddisplay=on label=' ')
      columnaxisopts=(griddisplay=on label=' ');
      layout prototype;
      scatterplot x=z y=y ;
      endlayout;
endlayout;
EndGraph;
end;
run;

proc sgrender data=sim template='myplot.panel';
run;

```

Figure 18.72 *t* Copula with Asymmetry

Quasi-Random Number Generators

Traditionally high-discrepancy pseudo-random number generators are used to generate innovations in Monte Carlo simulations. Loosely translated, a high-discrepancy pseudo-random number generator is one in which there is very little correlation between the current number generated and the past numbers generated. This property is ideal if indeed independence of the innovations is required. If, on the other hand, the efficient spanning of a multidimensional space is desired, a low discrepancy, quasi-random number generator can be used. A quasi-random number generator produces numbers that have no random component.

A simple one-dimensional quasi-random sequence is the van der Corput sequence. Given a prime number r ($r \geq 2$), any integer has a unique representation in terms of base r . A number in the interval $[0,1)$ can be created by inverting the representation base power by base power. For example, consider $r=3$ and $n=1$, 1 in base 3 is

$$1_{10} = 1 \cdot 3^0 = 1_3$$

When the powers of 3 are inverted,

$$\phi(1) = \frac{1}{3}$$

Also, 11 in base 3 is

$$11_{10} = 1 \cdot 3^2 + 2 \cdot 3^0 = 102_3$$

When the powers of 3 are inverted,

$$\phi(11) = \frac{1}{9} + 2 \cdot \frac{1}{3} = \frac{7}{9}$$

The first 10 numbers in this sequence $\phi(1) \dots \phi(10)$ are provided below

$$0, \frac{1}{3}, \frac{2}{3}, \frac{1}{9}, \frac{4}{9}, \frac{7}{9}, \frac{2}{9}, \frac{5}{9}, \frac{8}{9}, \frac{1}{27}$$

As the sequence proceeds, it fills in the gaps in a uniform fashion.

Several authors have expanded this idea to many dimensions. Two versions supported by the MODEL procedure are the Sobol sequence (QUASI=SOBOL) and the Faure sequence (QUASI=FAURE). The Sobol sequence is based on binary numbers and is generally computationally faster than the Faure sequence. The Faure sequence uses the dimensionality of the problem to determine the number base to use to generate the sequence. The Faure sequence has better distributional properties than the Sobol sequence for dimensions greater than 8.

As an example of the difference between a pseudo-random number and a quasi-random number, consider simulating a bivariate normal with 100 draws.

Figure 18.73 Kernel Density of a Bivariate Normal produced by 100 Faure-Random Draws

Figure 18.74 Kernel Density of a Bivariate Normal produced by 100 Pseudo-Random Draws

Solution Mode Output

The following SAS statements dynamically forecast the solution to a nonlinear equation:

```
proc model data=sashelp.citimon;
  parameters a 0.010708 b -0.478849 c 0.929304;
  lhur = 1/(a * ip) + b + c * lag(lhur);
  solve lhur / out=sim forecast dynamic;
run;
```

The first page of output produced by the SOLVE step is shown in Figure 18.75. This is the summary description of the model. The error message states that the simulation was aborted at observation 144 because of missing input values.

Figure 18.75 Solve Step Summary Output

OUT=	SIM
Solution Summary	
Variables Solved	1
Forecast Lag Length	1
Solution Method	NEWTON
CONVERGE=	1E-8
Maximum CC	0
Maximum Iterations	1
Total Iterations	143
Average Iterations	1
Observations Processed	
Read	145
Lagged	1
Solved	143
First	2
Last	145
Failed	1
Variables Solved For	LHUR

This solution summary table includes the names of the input data set and the output data set followed by a description of the model. The table also indicates that the solution method defaulted to Newton's method. The remaining output is defined as follows.

Maximum CC	is the maximum convergence value accepted by the Newton procedure. This number is always less than the value for the CONVERGE= option.
Maximum Iterations	is the maximum number of Newton iterations performed at each observation and each replication of Monte Carlo simulations.
Total Iterations	is the sum of the number of iterations required for each observation and each Monte Carlo simulation.
Average Iterations	is the average number of Newton iterations required to solve the system at each step.
Solved	is the number of observations used times the number of random replications selected plus one, for Monte Carlo simulations. The one additional simulation is the original unperturbed solution. For simulations that do not involve Monte Carlo, this number is the number of observations used.

Summary Statistics

The STATS and THEIL options are used to select goodness-of-fit statistics. Actual values must be provided in the input data set for these statistics to be printed. When the RANDOM= option is specified, the statistics do not include the unperturbed ($_REP_=0$) solution.

STATS Option Output

The following statements show the addition of the STATS and THEIL options to the model in the previous section:

```
proc model data=sashelp.citimon;
  parameters a 0.010708 b -0.478849 c 0.929304;
  lhur= 1/(a * ip) + b + c * lag(lhur) ;
  solve lhur / out=sim dynamic stats theil;
  range date to '01nov91'd;
run;
```

The STATS output in Figure 18.78 and the THEIL output in Figure 18.79 are generated.

Figure 18.78 STATS Output

The MODEL Procedure							
Dynamic Single-Equation Simulation							
Solution Range DATE = FEB1980 To NOV1991							
Descriptive Statistics							
Variable	N Obs	N	Actual		Predicted		
			Mean	Std Dev	Mean	Std Dev	
LHUR	142	142	7.0887	1.4509	7.2473	1.1465	
Statistics of fit							
Variable	N	Mean Error	Mean % Error	Mean Abs Error	Mean Abs % Error	RMS Error	RMS % Error
LHUR	142	0.1585	3.5289	0.6937	10.0001	0.7854	11.2452
Statistics of fit							
Variable	R-Square	Label					
LHUR	0.7049	UNEMPLOYMENT RATE: ALL WORKERS, 16 YEARS					

The number of observations (Nobs), the number of observations with both predicted and actual values nonmissing (N), and the mean and standard deviation of the actual and predicted values of the determined variables are printed first. The next set of columns in the output are defined as follows:

Mean Error	$\frac{1}{N} \sum_{j=1}^N (\hat{y}_j - y_j)$
Mean % Error	$\frac{100}{N} \sum_{j=1}^N (\hat{y}_j - y_j)/y_j$
Mean Abs Error	$\frac{1}{N} \sum_{j=1}^N \hat{y}_j - y_j $
Mean Abs % Error	$\frac{100}{N} \sum_{j=1}^N (\hat{y}_j - y_j)/y_j $
RMS Error	$\sqrt{\frac{1}{N} \sum_{j=1}^N (\hat{y}_j - y_j)^2}$
RMS % Error	$100 \sqrt{\frac{1}{N} \sum_{j=1}^N ((\hat{y}_j - y_j)/y_j)^2}$
R-square	$1 - SSE/CSSA$
SSE	$\sum_{j=1}^N (\hat{y}_j - y_j)^2$
SSA	$\sum_{j=1}^N (y_j)^2$
CSSA	$SSA - \left(\sum_{j=1}^N y_j\right)^2$
\hat{y}	predicted value
y	actual value

When the RANDOM= option is specified, the statistics do not include the unperturbed (_REP_=0) solution.

THEIL Option Output

The THEIL option specifies that Theil forecast error statistics be computed for the actual and predicted values and for the relative changes from lagged values. Mathematically, the quantities are

$$\hat{y}c = (\hat{y} - lag(y))/lag(y)$$

$$yc = (y - lag(y))/lag(y)$$

where $\hat{y}c$ is the relative change for the predicted value and yc is the relative change for the actual value.

Figure 18.79 THEIL Output

Theil Forecast Error Statistics								
Variable	N	MSE	Corr (R)	MSE Decomposition Proportions			Covar (UC)	
				Bias (UM)	Reg (UR)	Dist (UD)		
LHUR	142	0.6168	0.85	0.04	0.01	0.95	0.15	0.81

Theil Forecast Error Statistics			
Variable	Inequality Coef		Label
	U1	U	
LHUR	0.1086	0.0539	UNEMPLOYMENT RATE: ALL WORKERS, 16 YEARS

Theil Relative Change Forecast Error Statistics								
Variable	N	Relative Change MSE	Corr (R)	MSE Decomposition Proportions			Covar (UC)	
				Bias (UM)	Reg (UR)	Dist (UD)		
LHUR	142	0.0126	-0.08	0.09	0.85	0.06	0.43	0.47

Theil Relative Change Forecast Error Statistics			
Variable	Inequality Coef		Label
	U1	U	
LHUR	4.1226	0.8348	UNEMPLOYMENT RATE: ALL WORKERS, 16 YEARS

The columns have the following meaning:

Corr (R) is the correlation coefficient, ρ , between the actual and predicted values.

$$\rho = \frac{\text{cov}(y, \hat{y})}{\sigma_a \sigma_p}$$

where σ_p and σ_a are the standard deviations of the predicted and actual values.

Bias (UM) is an indication of systematic error and measures the extent to which the average values of the actual and predicted deviate from each other.

$$\frac{(E(y) - E(\hat{y}))^2}{\frac{1}{N} \sum_{t=1}^N (y_t - \hat{y}_t)^2}$$

Reg (UR) is defined as $(\sigma_p - \rho * \sigma_a)^2 / MSE$. Consider the regression

$$y = \alpha + \beta \hat{y}$$

If $\hat{\beta} = 1$, UR will equal zero.

Dist (UD) is defined as $(1 - \rho^2)\sigma_a\sigma_a/MSE$ and represents the variance of the residuals obtained by regressing yc on $\hat{y}c$.

Var (US) is the variance proportion. US indicates the ability of the model to replicate the degree of variability in the endogenous variable.

$$US = \frac{(\sigma_p - \sigma_a)^2}{MSE}$$

Covar (UC) represents the remaining error after deviations from average values and average variabilities have been accounted for.

$$UC = \frac{2(1 - \rho)\sigma_p\sigma_a}{MSE}$$

U1 is a statistic that measures the accuracy of a forecast defined as follows:

$$U1 = \frac{\sqrt{MSE}}{\sqrt{\frac{1}{N} \sum_{t=1}^N (y_t)^2}}$$

U is the Theil's inequality coefficient defined as follows:

$$U = \frac{\sqrt{MSE}}{\sqrt{\frac{1}{N} \sum_{t=1}^N (y_t)^2 + \frac{1}{N} \sum_{t=1}^N (\hat{y}_t)^2}}$$

MSE is the mean square error. In the case of the relative change Theil statistics, the MSE is computed as follows:

$$MSE = \frac{1}{N} \sum_{t=1}^N (\hat{y}c_t - yc_t)^2$$

More information about these statistics can be found in the references Maddala (1977, 344–347) and Pindyck and Rubinfeld (1981, 364–365).

Goal Seeking: Solving for Right-Hand-Side Variables

The process of computing input values that are needed to produce target results is often called *goal seeking*. To compute a goal-seeking solution, use a SOLVE statement that lists the variables you want to solve for and provide a data set that contains values for the remaining variables.

Consider the following demand model for packaged rice

$$\text{quantity demanded} = \alpha_1 + \alpha_2 \text{price}^{2/3} + \alpha_3 \text{income}$$

where *price* is the price of the package and *income* is disposable personal income. The only variable the company has control over is the price it charges for rice. This model is estimated by using the following simulated data and PROC MODEL statements:

```

data demand;
  do t=1 to 40;
    price = (rannor(10) +5) * 10;
    income = 8000 * t ** (1/8);
    demand = 7200 - 1054 * price ** (2/3) +
              7 * income + 100 * rannor(1);
    output;
  end;
run;

data goal;
  demand = 85000;
  income = 12686;
run;

```

The goal is to find the price the company would have to charge to meet a sales target of 85,000 units. To do this, a data set is created with a DEMAND variable set to 85000 and with an INCOME variable set to 12686, the last income value.

The desired price is then determined by using the following PROC MODEL statements:

```

proc model data=demand
  outmodel=demandModel;
  demand = a1 - a2 * price ** (2/3) + a3 * income;
  fit demand / outest=demest;
  solve price / estdata=demest data=goal solveprint;
run;

```

The SOLVEPRINT option prints the solution values, number of iterations, and final residuals at each observation. The SOLVEPRINT output from this solve is shown in Figure 18.80.

Figure 18.80 Goal Seeking, SOLVEPRINT Output

The MODEL Procedure							
Single-Equation Simulation							
Observation	1	Iterations	6	CC	0.000000	ERROR.demand	0.000000
Solution Values							
price							
33.59016							

The output indicates that it took six Newton iterations to determine the PRICE of 33.5902, which makes the DEMAND value within 16E-11 of the goal of 85,000 units.

Consider a more ambitious goal of 100,000 units. The output shown in Figure 18.81 indicates that the sales target of 100,000 units is not attainable according to this model.

```

data goal;
  demand = 100000;

```

```

income = 12686;
run;

proc model model=demandModel;
  solve price / estdata=demest data=goal solveprint;
run;

```

```

The program data vector with the error note indicates that even after 10 subiterations, the norm of the residuals could not be reduced. The sales target of 100,000 units are unattainable with the given model. You might need to reformulate your model or collect more data to more accurately reflect the market response.

Numerical Solution Methods

If the SINGLE option is not used, PROC MODEL computes values that simultaneously satisfy the model equations for the variables named in the SOLVE statement. PROC MODEL provides three iterative methods, Newton, Jacobi, and Seidel, for computing a simultaneous solution of the system of nonlinear equations.

Single-Equation Solution

For normalized form equation systems, the solution either can simultaneously satisfy all the equations or can be computed for each equation separately, by using the actual values of the solution variables in the current period to compute each predicted value. By default, PROC MODEL computes

a simultaneous solution. The SINGLE option in the SOLVE statement selects single-equation solutions.

Single-equation simulations are often made to produce residuals (which estimate the random terms of the stochastic equations) rather than the predicted values themselves. If the input data and range are the same as that used for parameter estimation, a static single-equation simulation reproduces the residuals of the estimation.

Newton's Method

The NEWTON option in the SOLVE statement requests Newton's method to simultaneously solve the equations for each observation. Newton's method is the default solution method. Newton's method is an iterative scheme that uses the derivatives of the equations with respect to the solution variables, \mathbf{J} , to compute a change vector as

$$\Delta \mathbf{y}^i = \mathbf{J}^{-1} \mathbf{q}(\mathbf{y}^i, \mathbf{x}, \boldsymbol{\theta})$$

PROC MODEL builds and solves \mathbf{J} by using efficient sparse matrix techniques. The solution variables \mathbf{y}^i at the i th iteration are then updated as

$$\mathbf{y}^{i+1} = \mathbf{y}^i + d \times \Delta \mathbf{y}^i$$

where d is a damping factor between 0 and 1 chosen iteratively so that

$$\|\mathbf{q}(\mathbf{y}^{i+1}, \mathbf{x}, \boldsymbol{\theta})\| < \|\mathbf{q}(\mathbf{y}^i, \mathbf{x}, \boldsymbol{\theta})\|$$

The number of subiterations allowed for finding a suitable d is controlled by the MAXSUBITER= option. The number of iterations of Newton's method allowed for each observation is controlled by MAXITER= option. See Ortega and Rheinbolt (1970) for more details.

Jacobi Method

The JACOBI option in the SOLVE statement selects a matrix-free alternative to Newton's method. This method is the traditional nonlinear Jacobi method found in the literature. The Jacobi method as implemented in PROC MODEL substitutes predicted values for the endogenous variables and iterates until a fixed point is reached. Then necessary derivatives are computed only for the diagonal elements of the jacobian, \mathbf{J} .

If the normalized form equation is

$$\mathbf{y} = \mathbf{f}(\mathbf{y}, \mathbf{x}, \boldsymbol{\theta})$$

the Jacobi iteration has the form

$$\mathbf{y}^{i+1} = \mathbf{f}(\mathbf{y}^i, \mathbf{x}, \boldsymbol{\theta})$$

Seidel Method

The Seidel method is an order-dependent alternative to the Jacobi method. The Seidel method is selected by the SEIDEL option in the SOLVE statement. The Seidel method is like the Jacobi method except that in the Seidel method the model is further edited to substitute the predicted values into the solution variables immediately after they are computed. Seidel thus differs from the other methods in that the values of the solution variables are not fixed within an iteration. With the other methods, the order of the equations in the model program makes no difference, but the Seidel method might work much differently when the equations are specified in a different sequence. Note that this fixed point method is the traditional nonlinear Seidel method found in the literature.

The iteration has the form

$$\mathbf{y}_j^{i+1} = \mathbf{f}(\hat{\mathbf{y}}^i, \mathbf{x}, \boldsymbol{\theta})$$

where \mathbf{y}_j^{i+1} is the j th equation variable at the i th iteration and

$$\hat{\mathbf{y}}^i = (y_1^{i+1}, y_2^{i+1}, y_3^{i+1}, \dots, y_{j-1}^{i+1}, y_j^i, y_{j+1}^i, \dots, y_g^i)'$$

If the model is recursive, and if the equations are in recursive order, the Seidel method converges at once. If the model is block-recursive, the Seidel method might converge faster if the equations are grouped by block and the blocks are placed in block-recursive order. The BLOCK option can be used to determine the block-recursive form.

Jacobi and Seidel Methods with General Form Equations

Jacobi and Seidel solution methods support general form equations.

There are two cases where derivatives are (automatically) computed. The first case is for equations with the solution variable on the right-hand side and on the left-hand side of the equation

$$y^i = f(\mathbf{x}, y^i)$$

In this case the derivative of `ERROR.y` with respect to y is computed, and the new y approximation is computed as

$$y^{i+1} = y^i - \frac{f(\mathbf{x}, y^i) - y^i}{\partial(f(\mathbf{x}, y^i) - y^i)/\partial y}$$

The second case is a system of equations that contains one or more `EQ.var` equations. In this case, a heuristic algorithm is used to make the assignment of a unique solution variable to each general form equation. Use the DETAILS option in the SOLVE statement to print a listing of the assigned variables.

Once the assignment is made, the new y approximation is computed as

$$y^{i+1} = y^i - \frac{f(\mathbf{x}, \mathbf{y}^i) - y^i}{\partial(f(\mathbf{x}, \mathbf{y}^i) - y^i)/\partial y}$$

If k is the number of general form equations, then k derivatives are required.

The convergence properties of the Jacobi and Seidel solution methods remain significantly poorer than the default Newton's method.

Comparison of Methods

Newton's method is the default and should work better than the others for most small- to medium-sized models. The Seidel method is always faster than the Jacobi for recursive models with equations in recursive order. For very large models and some highly nonlinear smaller models, the Jacobi or Seidel methods can sometimes be faster. Newton's method uses more memory than the Jacobi or Seidel methods.

Both the Newton's method and the Jacobi method are order-invariant in the sense that the order in which equations are specified in the model program has no effect on the operation of the iterative solution process. In order-invariant methods, the values of the solution variables are fixed for the entire execution of the model program. Assignments to model variables are automatically changed to assignments to corresponding equation variables. Only after the model program has completed execution are the results used to compute the new solution values for the next iteration.

Troubleshooting Problems

In solving a simultaneous nonlinear dynamic model you might encounter some of the following problems.

Missing Values

For SOLVE tasks, there can be no missing parameter values. Missing right-hand-side variables result in missing left-hand-side variables for that observation.

Unstable Solutions

A solution might exist but be unstable. An unstable system can cause the Jacobi and Seidel methods to diverge.

Explosive Dynamic Systems

A model might have well-behaved solutions at each observation but be dynamically unstable. The solution might oscillate wildly or grow rapidly with time.

Propagation of Errors

During the solution process, solution variables can take on values that cause computational errors. For example, a solution variable that appears in a LOG function might be positive at the solution but might be given a negative value during one of the iterations. When computational errors occur, missing values are generated and propagated, and the solution process might collapse.

Convergence Problems

The following items can cause convergence problems:

- There are illegal function values (for example $\sqrt{-1}$).
- There are local minima in the model equation.
- No solution exists.
- Multiple solutions exist.
- Initial values are too far from the solution.
- The CONVERGE= value is too small.

When PROC MODEL fails to find a solution to the system, the current iteration information and the program data vector are printed. The simulation halts if actual values are not available for the simulation to proceed. Consider the following program, which produces the output shown in Figure 18.82:

```
data test1;
  do t=1 to 50;
    x1 = sqrt(t) ;
    y = .;
    output;
  end;

proc model data=test1;
  exogenous x1 ;
  control a1 -1 b1 -29 c1 -4 ;
  y = a1 * sqrt(y) + b1 * x1 * x1 + c1 * lag(x1);
  solve y / out=sim forecast dynamic ;
run;
```

b1:                 -29     c1:           -4          x1:           1.41421
y:                  -0.00109
@PRED.y/@y:         .      @ERROR.y/@y:      .

NOTE: Check for missing input data or uninitialized lags.
      (Note that the LAG and DIF functions return missing values for the
initial lag starting observations. This is a change from the 1982 and earlier
versions of SAS/ETS which returned zero for uninitialized lags.)
NOTE: Simulation aborted.

```

At the first observation, a solution to the following equation is attempted:

$$y = -\sqrt{y} - 62$$

There is no solution to this problem. The iterative solution process got as close as it could to making Y negative while still being able to evaluate the model. This problem can be avoided in this case by altering the equation.

In other models, the problem of missing values can be avoided by either altering the data set to provide better starting values for the solution variables or by altering the equations.

You should be aware that, in general, a nonlinear system can have any number of solutions and the solution found might not be the one that you want. When multiple solutions exist, the solution that is found is usually determined by the starting values for the iterations. If the value from the input data set for a solution variable is missing, the starting value for it is taken from the solution of the last period (if nonmissing) or else the solution estimate is started at 0.

Iteration Output

The iteration output, produced by the ITPRINT option, is useful in determining the cause of a convergence problem. The ITPRINT option forces the printing of the solution approximation and equation errors at each iteration for each observation. A portion of the ITPRINT output from the following statements is shown in Figure 18.83.

```

proc model data=test1;
  exogenous x1 ;
  control a1 -1 b1 -29 c1 -4 ;
  y = a1 * sqrt(abs(y)) + b1 * x1 * x1 + c1 * lag(x1);
  solve y / out=sim forecast dynamic itprint;
run;

```

For each iteration, the equation with the largest error is listed in parentheses after the Newton convergence criteria measure. From this output you can determine which equation or equations in the system are not converging well.

Numerical Integration

The differential equation system is numerically integrated to obtain a solution for the derivative variables at each data point. The integration is performed by evaluating the provided model at multiple points between each data point. The integration method used is a variable order, variable step-size backward difference scheme; for more detailed information, see Aiken (1985) and Byrne and Hindmarsh (1975). The step size or time step is chosen to satisfy a *local truncation error* requirement. The term *truncation error* comes from the fact that the integration scheme uses a truncated series expansion of the integrated function to do the integration. Because the series is truncated, the integration scheme is within the truncation error of the true value.

To further improve the accuracy of the integration, the total integration time is broken up into small intervals (time steps or step sizes), and the integration scheme is applied to those intervals. The integration at each time step uses the values computed at the previous time step so that the truncation error tends to accumulate. It is usually not possible to estimate the global error with much precision. The best that can be done is to monitor and to control the local truncation error, which is the truncation error committed at each time step relative to

$$d = \max_{0 \leq t \leq T} (\|y(t)\|_{\infty}, 1)$$

where $y(t)$ is the integrated variable. Furthermore, the $y(t)$ s are dynamically scaled to within two orders of magnitude of one to keep the error monitoring well-behaved.

The local truncation error requirement defaults to 1.0E-9. You can specify the LTEBOUND= option to modify that requirement. The LTEBOUND= option is a relative measure of accuracy, so a value smaller than 1.0E-10 is usually not practical. A larger bound increases the speed of the simulation and estimation but decreases the accuracy of the results. If the LTEBOUND= option is set too small, the integrator is not able to take time steps small enough to satisfy the local truncation error requirement and still have enough machine precision to compute the results. Since the integrations are scaled to within 1.0E-2 of one, the simulated values should be correct to at least seven decimal places.

There is a default minimum time step of 1.0E-14. This minimum time step is controlled by the MINTIMESTEP= option and the machine epsilon. If the minimum time step is smaller than the machine epsilon times the final time value, the minimum time step is increased automatically.

For the points between each observation in the data set, the values for nonintegrated variables in the data set are obtained from a linear interpolation from the two closest points. Lagged variables can be used with integrations, but their values are discrete and are not interpolated between points. Lagging, therefore, can then be used to input step functions into the integration.

The derivatives necessary for estimation (the gradient with respect to the parameters) and goal seeking (the Jacobian) are computed by numerically integrating analytical derivatives. The accuracy of the derivatives is controlled by the same integration techniques mentioned previously.

Limitations

There are limitations to the types of differential equations that can be solved or estimated. One type is an explosive differential equation (finite escape velocity) for which the following differential equation is an example:

$$y' = a \times y, a > 0$$

If this differential equation is integrated too far in time, y exceeds the maximum value allowed on the computer, and the integration terminates.

Likewise, differential systems that are singular cannot be solved or estimated in general. For example, consider the following differential system:

$$\begin{aligned} x' &= -y' + 2x + 4y + \exp(t) \\ y' &= -x' + y + \exp(4t) \end{aligned}$$

This system has an analytical solution, but an accurate numerical solution is very difficult to obtain. The reason is that y' and x' cannot be isolated on the left-hand side of the equation. If the equation is modified slightly to

$$\begin{aligned} x' &= -y' + 2x + 4y + \exp(t) \\ y' &= x' + y + \exp(4t) \end{aligned}$$

the system is nonsingular, but the integration process could still fail or be extremely slow. If the MODEL procedure encounters either system, a warning message is issued.

This system can be rewritten as the following recursive system, which can be estimated and simulated successfully with the MODEL procedure:

$$\begin{aligned} x' &= 0.5y + 0.5\exp(4t) + x + 1.5y - 0.5\exp(t) \\ y' &= x' + y + \exp(4t) \end{aligned}$$

Petzold (1982) mentions a class of differential algebraic equations that, when integrated numerically, could produce incorrect or misleading results. An example of such a system is

$$\begin{aligned} y_2'(t) &= y_1(t) + g_1(t) \\ 0 &= y_2(t) + g_2(t) \end{aligned}$$

The analytical solution to this system depends on g and its derivatives at the current time only and not on its initial value or past history. You should avoid systems of this and other similar forms mentioned in Petzold (1982).

SOLVE Data Sets

SDATA= Input Data Set

The SDATA= option reads a cross-equation covariance matrix from a data set. The covariance matrix read from the SDATA= data set specified in the SOLVE statement is used to generate random equation errors when the RANDOM= option specifies Monte Carlo simulation.

Typically, the SDATA= data set is created by the OUTS= option in a previous FIT statement. (The OUTS= data set from a FIT statement can be read back in by a SOLVE statement in the same PROC MODEL step.)

You can create an input SDATA= data set by using the DATA step. PROC MODEL expects to find a character variable `_NAME_` in the SDATA= data set as well as variables for the equations in the estimation or solution. For each observation with a `_NAME_` value that matches the name of an equation, PROC MODEL fills the corresponding row of the **S** matrix with the values of the names of equations found in the data set. If a row or column is omitted from the data set, an identity matrix row or column is assumed. Missing values are ignored. Since the **S** matrix is symmetric, you can include only a triangular part of the **S** matrix in the SDATA= data set with the omitted part indicated by missing values. If the SDATA= data set contains multiple observations with the same `_NAME_`, the last values supplied for the `_NAME_` variable are used. The section “OUTS= Data Set” on page 1162 contains more details on the format of this data set.

Use the TYPE= option to specify the type of estimation method used to produce the **S** matrix you want to input.

ESTDATA= Input Data Set

The ESTDATA= option specifies an input data set that contains an observation with values for some or all of the model parameters. It can also contain observations with the rows of a covariance matrix for the parameters.

When the ESTDATA= option is used, parameter values are set from the first observation. If the RANDOM= option is used and the ESTDATA= data set contains a covariance matrix, the covariance matrix of the parameter estimates is read and used to generate pseudo-random shocks to the model parameters for Monte Carlo simulation. These random perturbations have a multivariate normal distribution with the covariance matrix read from the ESTDATA= data set.

The ESTDATA= data set is usually created by the OUTEST= option in a FIT statement. The OUTEST= data set contains the parameter estimates produced by the FIT statement and also contains the estimated covariance of the parameter estimates if the OUTCOV option is used. This OUTEST= data set can be read in by the ESTDATA= option in a SOLVE statement.

You can also create an ESTDATA= data set with a SAS DATA step program. The data set must contain a numeric variable for each parameter to be given a value or covariance column. The name of the variable in the ESTDATA= data set must match the name of the parameter in the model. Parameters with names longer than 32 characters cannot be set from an ESTDATA= data set. The

data set must also contain a character variable `_NAME_` of length 32. `_NAME_` has a blank value for the observation that gives values to the parameters. `_NAME_` contains the name of a parameter for observations that define rows of the covariance matrix.

More than one set of parameter estimates and covariances can be stored in the `ESTDATA=` data set if the observations for the different estimates are identified by the variable `_TYPE_`. `_TYPE_` must be a character variable of length eight. The `TYPE=` option is used to select for input the part of the `ESTDATA=` data set for which the value of the `_TYPE_` variable matches the value of the `TYPE=` option.

OUT= Data Set

The `OUT=` data set contains solution values, residual values, and actual values of the solution variables.

The `OUT=` data set contains the following variables:

- BY variables
- RANGE variable
- ID variables
- `_TYPE_`, a character variable of length eight that identifies the type of observation. The `_TYPE_` variable can be `PREDICT`, `RESIDUAL`, `ACTUAL`, or `ERROR`.
- `_MODE_`, a character variable of length eight that identifies the solution mode. `_MODE_` takes the value `FORECAST` or `SIMULATE`.
- if lags are used, a numeric variable, `_LAG_`, that contains the number of dynamic lags that contribute to the solution. The value of `_LAG_` is always zero for `STATIC` mode solutions. `_LAG_` is set to a missing value for lag-starting observations.
- if the `RANDOM=` option is used, `_REP_`, a numeric variable that contains the replication number. For example, if `RANDOM=10`, each input observation results in eleven output observations with `_REP_` values 0 through 10. The observations with `_REP_=0` are from the unperturbed solution. (The random-number generator functions are suppressed, and the parameter and endogenous perturbations are zero when `_REP_=0`.)
- `_ERRORS_`, a numeric variable that contains the number of errors that occurred during the execution of the program for the last iteration for the observation. If the solution failed to converge, this is counted as one error, and the `_ERRORS_` variable is made negative.
- solution and other variables. The solution variables contain solution or predicted values for `_TYPE_=PREDICT` observations, residuals for `_TYPE_=RESIDUAL` observations, or actual values for `_TYPE_=ACTUAL` observations. The other model variables, and any other variables read from the input data set, are always actual values from the input data set.
- any other variables named in the `OUTVARS` statement. These can be program variables computed by the model program, `CONTROL` variables, parameters, or special variables in

the model program. Compound variable names longer than 32 characters are truncated in the OUT= data set.

By default, only the predicted values are written to the OUT= data set. The OUTRESID, OUTACTUAL, and OUTERERROR options are used to add the residual, actual, and ERROR. values, respectively, to the data set.

For examples of the OUT= data set, see [Example 18.6](#).

DATA= Input Data Set

The input data set should contain all of the exogenous variables and should supply nonmissing values for them for each period to be solved.

Solution variables can be supplied in the input data set and are used as follows:

- to supply initial lags. For example, if the lag length of the model is three, three observations are read in to feed the lags before any solutions are computed.
- to evaluate the goodness of fit. Goodness-of-fit measures are computed based on the difference between the solved values and the actual values supplied from the data set.
- to supply starting values for the iterative solution. If the value from the input data set for a solution variable is missing, the starting value for it is taken from the solution of the last period (if nonmissing) or else the solution estimate is started at zero.
- for STATIC mode solutions, actual values from the data set are used by the lagging functions for the solution variables.
- for FORECAST mode solutions, actual values from the data set are used as the solution values when nonmissing.

Programming Language Overview: MODEL Procedure

Variables in the Model Program

Variable names are alphanumeric but must start with a letter. The length is limited to 32 characters.

PROC MODEL uses several classes of variables, and different variable classes are treated differently. The variable class is controlled by *declaration statements*: the VAR, ENDOGENOUS, and EXOGENOUS statements for model variables, the PARAMETERS statement for parameters, and the CONTROL statement for control class variables. These declaration statements have several valid abbreviations. Various *internal variables* are also made available to the model program to allow

communication between the model program and the procedure. RANGE, ID, and BY variables are also available to the model program. Those variables not declared as any of the preceding classes are *program variables*.

Some classes of variables can be lagged; that is, their value at each observation is remembered, and previous values can be referred to by the lagging functions. Other classes have only a single value and are not affected by lagging functions. For example, parameters have only one value and are not affected by lagging functions; therefore, if P is a parameter, $DIF_n(P)$ is always 0, and $LAG_n(P)$ is always the same as P for all values of n .

The different variable classes and their roles in the model are described in the following.

Model Variables

Model variables are declared by VAR, ENDOGENOUS, or EXOGENOUS statements, or by FIT and SOLVE statements. The model variables are the variables that the model is intended to explain or predict.

PROC MODEL enables you to use expressions on the left-hand side of the equal sign to define model equations. For example, a log-linear model for Y can be written as

$$\log(y) = a + b * x;$$

Previously, only a variable name was allowed on the left-hand side of the equal sign.

The text on the left-hand side of the equation serves as the equation name used to identify the equation in printed output, in the OUT= data sets, and in FIT or SOLVE statements. To refer to equations specified by using left-hand side expressions (in the FIT statement, for example), place the left-hand side expression in quotes. For example, the following statements fit a log-linear model to the dependent variable Y:

```
proc model data=in;
  log(y) = a + b * x;
  fit "log(y)";
run;
```

The estimation and simulation is performed by transforming the models into general form equations. No actual or predicted value is available for general form equations, so no R^2 or adjusted R^2 is computed.

Equation Variables

An equation variable is one of several special variables used by PROC MODEL to control the evaluation of model equations. An equation variable name consists of one of the prefixes EQ, RESID, ERROR, PRED, or ACTUAL, followed by a period and the name of a model equation.

Equation variable names can appear in parts of the PROC MODEL printed output, and they can be used in the model program. For example, RESID-prefixed variables can be used in LAG functions to define equations with moving-average error terms. See the section “[Autoregressive Moving-Average Error Processes](#)” on page 1138 for details.

The meaning of these prefixes is detailed in the section “[Equation Translations](#)” on page 1204.

Parameters

Parameters are variables that have the same value for each observation. Parameters can be given values or can be estimated by fitting the model to data. During the SOLVE stage, parameters are treated as constants. If no estimation is performed, the SOLVE stage uses the initial value provided in the ESTDATA= data set, the MODEL= file, or in the PARAMETER statement, as the value of the parameter.

The PARAMETERS statement declares the parameters of the model. Parameters are not lagged, and they cannot be changed by the model program.

Control Variables

Control variables supply constant values to the model program that can be used to control the model in various ways. The CONTROL statement declares control variables and specifies their values. A control variable is like a parameter except that it has a fixed value and is not estimated from the data.

Control variables are not reinitialized before each pass through the data and can thus be used to retain values between passes. You can use control variables to vary the program logic. Control variables are not affected by lagging functions.

For example, if you have two versions of an equation for a variable Y, you could put both versions in the model and, by using a CONTROL statement to select one of them, produce two different solutions to explore the effect the choice of equation has on the model, as shown in the following statements:

```
select (case);
  when (1) y = ...first version of equation... ;
  when (2) y = ...second version of equation... ;
end;

control case 1;
solve / out=case1;
run;

control case 2;
solve / out=case2;
run;
```

RANGE, ID, and BY Variables

The RANGE statement controls the range of observations in the input data set that is processed by PROC MODEL. The ID statement lists variables in the input data set that are used to identify observations in the printout and in the output data set. The BY statement can be used to make PROC MODEL perform a separate analysis for each BY group. The variable in the RANGE statement, the ID variables, and the BY variables are available for the model program to examine, but their values should not be changed by the program. The BY variables are not affected by lagging functions.

Internal Variables

You can use several internal variables in the model program to communicate with the procedure. For example, if you want PROC MODEL to list the values of all the variables when more than 10 iterations are performed and the procedure is past the 20th observation, you can write

```
if _obs_ > 20 then if _iter_ > 10 then _list_ = 1;
```

Internal variables are not affected by lagging functions, and they cannot be changed by the model program except as noted. The following internal variables are available. The variables are all numeric except where noted.

- _ERRORS_** is a flag that is set to 0 at the start of program execution and is set to a nonzero value whenever an error occurs. The program can also set the **_ERRORS_** variable.
- _ITER_** is the iteration number. For FIT tasks, the value of **_ITER_** is negative for preliminary grid-search passes. The iterative phase of the estimation starts with iteration 0. After the estimates have converged, a final pass is made to collect statistics with **_ITER_** set to a missing value. Note that at least one pass, and perhaps several subiteration passes as well, is made for each iteration. For SOLVE tasks, **_ITER_** counts the iterations used to compute the simultaneous solution of the system.
- _LAG_** is the number of dynamic lags that contribute to the solution at the current observation. **_LAG_** is always 0 for FIT tasks and for STATIC solutions. **_LAG_** is set to a missing value during the lag starting phase.
- _LIST_** is a list flag that is set to 0 at the start of program execution. The program can set **_LIST_** to a nonzero value to request a listing of the values of all the variables in the program after the program has finished executing.
- _METHOD_** is the solution method in use for SOLVE tasks. **_METHOD_** is set to a blank value for FIT tasks. **_METHOD_** is a character-valued variable. Values are NEWTON, JACOBI, SIEDEL, or ONEPASS.
- _MODE_** takes the value ESTIMATE for FIT tasks and the value SIMULATE or FORECAST for SOLVE tasks. **_MODE_** is a character-valued variable.
- _NMISS_** is the number of missing or otherwise unusable observations during the model estimation. For FIT tasks, **_NMISS_** is initially set to 0; at the start of each

	iteration, <code>_NMISS_</code> is set to the number of unusable observations for the previous iteration. For SOLVE tasks, <code>_NMISS_</code> is set to a missing value.
<code>_NUSED_</code>	is the number of nonmissing observations used in the estimation. For FIT tasks, PROC MODEL initially sets <code>_NUSED_</code> to the number of parameters; at the start of each iteration, <code>_NUSED_</code> is reset to the number of observations used in the previous iteration. For SOLVE tasks, <code>_NUSED_</code> is set to a missing value.
<code>_OBS_</code>	counts the observations being processed. <code>_OBS_</code> is negative or 0 for observations in the lag starting phase.
<code>_REP_</code>	is the replication number for Monte Carlo simulation when the RANDOM= option is specified in the SOLVE statement. <code>_REP_</code> is 0 when the RANDOM= option is not used and for FIT tasks. When <code>_REP_=0</code> , the random-number generator functions always return 0.
<code>_WEIGHT_</code>	is the weight of the observation. For FIT tasks, <code>_WEIGHT_</code> provides a weight for the observation in the estimation. <code>_WEIGHT_</code> is initialized to 1.0 at the start of execution for FIT tasks. For SOLVE tasks, <code>_WEIGHT_</code> is ignored.

Program Variables

Variables not in any of the other classes are called program variables. Program variables are used to hold intermediate results of calculations. Program variables are reinitialized to missing values before each observation is processed. Program variables can be lagged. The RETAIN statement can be used to give program variables initial values and enable them to keep their values between observations.

Character Variables

PROC MODEL supports both numeric and character variables. Character variables are not involved in the model specification but can be used to label observations, to write debugging messages, or for documentation purposes. All variables are numeric unless they are the following.

- character variables in a DATA= SAS data set
- program variables assigned a character value
- declared to be character by a LENGTH or ATTRIB statement

Equation Translations

Equations written in normalized form are always automatically converted to general form equations. For example, when a normalized form equation such as

$$y = a + b*x;$$

is encountered, it is translated into the equations

```
PRED.y = a + b*x;
RESID.y = PRED.y - ACTUAL.y;
ERROR.y = PRED.y - y;
```

If the same system is expressed as the following general form equation, then this equation is used unchanged.

```
EQ.y = y - a + b*x;
```

This makes it easy to solve for arbitrary variables and to modify the error terms for autoregressive or moving average models.

Use the LIST option to see how this transformation is performed. For example, the following statements produce the listing shown in Figure 18.84.

```
proc model data=line list;
  y = a1 + b1*x1 + c1*x2;
  fit y;
run;
```

Figure 18.84 LIST Output

The MODEL Procedure		
Listing of Compiled Program Code		
Stmt	Line:Col	Statement as Parsed
1	3884:4	PRED.y = a1 + b1 * x1 + c1 * x2;
1	3884:4	RESID.y = PRED.y - ACTUAL.y;
1	3884:4	ERROR.y = PRED.y - y;

PRED.Y is the predicted value of Y, and ACTUAL.Y is the value of Y in the data set. The predicted value minus the actual value, RESID.Y, is then the error term, ϵ , for the original Y equation. Note that the residuals obtained from the OUTRESID option in the OUT=dataset for both the FIT and SOLVE statements are defined as *actual – predicted*, the negative of RESID.Y. See the section “Syntax: MODEL Procedure” on page 1012 for details. ACTUAL.Y and Y have the same value for parameter estimation. For solve tasks, ACTUAL.Y is still the value of Y in the data set but Y becomes the solved value; the value that satisfies $PRED.Y - Y = 0$.

The following are the equation variable definitions.

EQ. The value of an EQ.-prefixed equation variable (normally used to define a general form equation) represents the failure of the equation to hold. When the EQ.name variable is 0, the name equation is satisfied.

RESID. The RESID.name variables represent the stochastic parts of the equations and are used to define the objective function for the estimation process. A RESID.-

prefixed equation variable is like an EQ.-prefixed variable but makes it possible to use or transform the stochastic part of the equation. The RESID. equation is used in place of the ERROR. equation for model solutions if it has been reassigned or used in the equation.

- ERROR.** An ERROR.*name* variable is like an EQ.-prefixed variable, except that it is used only for model solution and does not affect parameter estimation.
- PRED.** For a normalized form equation (specified by assignment to a model variable), the PRED.*name* equation variable holds the predicted value, where *name* is the name of both the model variable and the corresponding equation. (PRED.-prefixed variables are not created for general form equations.)
- ACTUAL.** For a normalized form equation (specified by assignment to a model variable), the ACTUAL.*name* equation variable holds the value of the *name* model variable read from the input data set.
- DETR.** The DETR.*name* variable defines a differential equation. Once defined, it might be used on the right-hand side of another equation.
- H.** The H.*name* variable specifies the functional form for the variance of the named equation.
- GMM_H.** This is created for H.*vars* and is the moment equation for the variance for GMM. This variable is used only for GMM.

```
GMM_H.name = RESID.name**2 - H.name;
```

- MSE.** The MSE.*y* variable contains the value of the mean squared error for *y* at each iteration. An MSE. variable is created for each dependent/endogenous variable in the model. These variables can be used to specify the missing lagged values in the estimation and simulation of GARCH type models.

```
demret = intercept ;
h.demret = arch0 +
            arch1 * xlag( resid.demret ** 2, mse.demret) +
            garch1 * xlag(h.demret, mse.demret) ;
```

- NRESID.** This is created for H.*vars* and is the normalized residual of the variable *<name>*. The formula is

```
NRESID.name = RESID.name/ sqrt(H.name) ;
```

The three equation variable prefixes, RESID., ERROR., and EQ. allow for control over the objective function for the FIT, the SOLVE, or both the FIT and the SOLVE stages. For FIT tasks, PROC MODEL looks first for a RESID.*name* variable for each equation. If defined, the RESID.-prefixed equation variable is used to define the objective function for the parameter estimation process. Otherwise, PROC MODEL looks for an EQ.-prefixed variable for the equation and uses it instead.

For SOLVE tasks, PROC MODEL looks first for an ERROR.*name* variable for each equation. If defined, the ERROR.-prefixed equation variable is used for the solution process. Otherwise, PROC MODEL looks for an EQ.-prefixed variable for the equation and uses it instead. To solve the simultaneous equation system, PROC MODEL computes values of the solution variables (the model variables being solved for) that make all of the ERROR.*name* and EQ.*name* variables close to 0.

Derivatives

Nonlinear modeling techniques require the calculation of derivatives of certain variables with respect to other variables. The MODEL procedure includes an analytic differentiator that determines the model derivatives and generates program code to compute these derivatives. When parameters are estimated, the MODEL procedure takes the derivatives of the equation with respect to the parameters. When the model is solved, Newton's method requires the derivatives of the equations with respect to the variables solved for.

PROC MODEL uses exact mathematical formulas for derivatives of non-user-defined functions. For other functions, numerical derivatives are computed and used.

The differentiator differentiates the entire model program, including the conditional logic and flow of control statements. Delayed definitions, as when the LAG of a program variable is referred to before the variable is assigned a value, are also differentiated correctly.

The differentiator includes optimization features that produce efficient code for the calculation of derivatives. However, when flow of control statements such as GOTO statements are used, the optimization process is impeded, and less efficient code for derivatives might be produced. Optimization is also reduced by conditional statements, iterative DO loops, and multiple assignments to the same variable.

The table of derivatives is printed with the LISTDER option. The code generated for the computation of the derivatives is printed with the LISTCODE option.

Derivative Variables

When the differentiator needs to generate code to evaluate the expression for the derivative of a variable, the result is stored in a special derivative variable. Derivative variables are not created when the derivative expression reduces to a previously computed result, a variable, or a constant. The names of derivative variables, which might sometimes appear in the printed output, have the form *@obj /@wrt*, where *obj* is the variable whose derivative is being taken and *wrt* is the variable that the differentiation is with respect to. For example, the derivative variable for the derivative of *Y* with respect to *X* is named *@Y/@X*.

The derivative variables can be accessed or used as part of the model program using the GETDER() function.

GETDER(*x*, *a*) the derivative of *x* with respect to *a*.

GETDER(*x*, *a*, *b*) the second derivative of *x* with respect to *a* and *b*.

The main purpose of the GETDER() function is for surfacing the derivatives so they can be stored in a data set for further processing. Only derivatives that are implied by the problem are available to the GETDER() function. When derivatives are requested that aren't already created, a missing value will be returned. The derivative of the GETDER() function is always zero so the results of the GETDER() function shouldn't be used in any of the equations in the FIT or the SOLVE statement.

The following example adds the gradient of the PRED.y value with respect to the parameters to the OUT= data set.

```
proc model data=line ;
  y = a1 + b1**2 *x1 + c1*x2;
  Dy_a1 = getder(PRED.y, a1);
  Dy_b1 = getder(PRED.y, b1);
  Dy_c1 = getder(PRED.y, c1);
  outvars Dy_a1 Dy_b1 Dy_c1;
  fit y / out=grad;
run;
```

Mathematical Functions

The following is a brief summary of SAS functions that are useful for defining models. Additional functions and details are in *SAS Language: Reference*. Information about creating new functions can be found in *SAS/BASE Software: Procedure Reference*, Chapter 18, “The FCMP Procedure.”

ABS(x)	the absolute value of x
ARCOS(x)	the arccosine in radians of x ; x should be between -1 and 1 .
ARSIN(x)	the arcsine in radians of x ; x should be between -1 and 1 .
ATAN(x)	the arctangent in radians of x
COS(x)	the cosine of x ; x is in radians.
COSH(x)	the hyperbolic cosine of x
EXP(x)	e^x
LOG(x)	the natural logarithm of x
LOG10(x)	the log base ten of x
LOG2(x)	the log base two of x
SIN(x)	the sine of x ; x is in radians.
SINH(x)	the hyperbolic sine of x
SQRT(x)	the square root of x
TAN(x)	the tangent of x ; x is in radians and is not an odd multiple of $\pi/2$.
TANH(x)	the hyperbolic tangent of x

Random-Number Functions

The MODEL procedure provides several functions for generating random numbers for Monte Carlo simulation. These functions use the same generators as the corresponding SAS DATA step functions.

The following random number functions are supported: RANBIN, RANCAU, RAND, RANEXP, RANGAM, RANNOR, RANPOI, RANTBL, RANTRI, and RANUNI. For more information, refer to *SAS Language: Reference*.

Each reference to a random number function sets up a separate pseudo-random sequence. Note that this means that two calls to the same random function with the same seed produce identical results. This is different from the behavior of the random number functions used in the SAS DATA step. For example, the following statements produce identical values for X and Y, but Z is from an independent pseudo-random sequence:

```
x=rannor(123);
y=rannor(123);
z=rannor(567);
q=rand('BETA', 1, 12);
```

For FIT tasks, all random number functions always return 0. For SOLVE tasks, when Monte Carlo simulation is requested, a random number function computes a new random number on the first iteration for an observation (if it is executed on that iteration) and returns that same value for all later iterations of that observation. When Monte Carlo simulation is not requested, random number functions always return 0.

Functions across Time

PROC MODEL provides four types of special built-in functions that refer to the values of variables and expressions in previous time periods. These functions have the following forms where n represents the number of periods, x is any expression, and the argument i is a variable or expression that gives the lag length ($0 \leq i \leq n$). If the index value i is omitted, the maximum lag length n is used.

$LAGn (< i, > x)$ returns the i th lag of x , where n is the maximum lag;

$DIFn (x)$ is the difference of x at lag n

$ZLAGn (< i, > x)$ returns the i th lag of x , where n is the maximum lag, with missing lags replaced with zero

$XLAGn (x, y)$ returns the n th lag of x if x is nonmissing, or y if x is missing

$ZDIFn (x)$ is the difference with lag length truncated and missing values converted to zero; x is the variable or expression to compute the moving average of

$MOVAVGn(x)$ is the moving average if X_t denotes the observation at time point t , to ensure compatibility with the number n of observations used to calculate the moving average $MOVAVGn$, the following definition is used:

$$MOVAVGn(X_t) = \frac{X_t + X_{t-1} + X_{t-2} + \dots + X_{t-n+1}}{n}$$

The moving average calculation for SAS 9.1 and earlier releases is as follows:

$$MOVAVGn(X_t) = \frac{X_t + X_{t-1} + X_{t-2} + \dots + X_{t-n}}{n + 1}$$

Missing values of x are omitted in computing the average.

If you do not specify n , the number of periods is assumed to be one. For example, $\text{LAG}(X)$ is the same as $\text{LAG1}(X)$. No more than four digits can be used with a lagging function; that is, LAG9999 is the greatest LAG function, ZDIF9999 is the greatest ZDIF function, and so on.

The LAG functions get values from previous observations and make them available to the program. For example, $\text{LAG}(X)$ returns the value of the variable X as it was computed in the execution of the program for the preceding observation. The expression $\text{LAG2}(X+2*Y)$ returns the value of the expression $X+2*Y$, computed by using the values of the variables X and Y that were computed by the execution of the program for the observation two periods ago.

The DIF functions return the difference between the current value of a variable or expression and the value of its LAG. For example, $\text{DIF2}(X)$ is a short way of writing $X-\text{LAG2}(X)$, and $\text{DIF15}(\text{SQRT}(2*Z))$ is a short way of writing $\text{SQRT}(2*Z)-\text{LAG15}(\text{SQRT}(2*Z))$.

The ZLAG and ZDIF functions are like the LAG and DIF functions, but they are not counted in the determination of the program lag length, and they replace missing values with 0s. The ZLAG function returns the lagged value if the lagged value is nonmissing, or 0 if the lagged value is missing. The ZDIF function returns the differenced value if the differenced value is nonmissing, or 0 if the value of the differenced value is missing. The ZLAG function is especially useful for models with ARMA error processes. See the next section for details.

Lag Logic

The LAG and DIF lagging functions in the MODEL procedure are different from the queuing functions with the same names in the DATA step. Lags are determined by the final values that are set for the program variables by the execution of the model program for the observation. This can have upsetting consequences for programs that take lags of program variables that are given different values at various places in the program, as shown in the following statements:

```
temp = x + w;
t    = lag( temp );
temp = q - r;
s    = lag( temp );
```

The expression $\text{LAG}(\text{TEMP})$ always refers to $\text{LAG}(Q-R)$, never to $\text{LAG}(X+W)$, since $Q-R$ is the final value assigned to the variable TEMP by the model program. If $\text{LAG}(X+W)$ is wanted for T , it should be computed as $T=\text{LAG}(X+W)$ and not $T=\text{LAG}(\text{TEMP})$, as in the preceding example.

Care should also be exercised in using the DIF functions with program variables that might be reassigned later in the program. For example, the program

```
temp = x ;
s    = dif( temp );
temp = 3 * y;
```

computes values for S equivalent to

```
s = x - lag( 3 * y );
```

Note that in the preceding examples, TEMP is a program variable, *not* a model variable. If it were a model variable, the assignments to it would be changed to assignments to a corresponding equation variable.

Note that whereas LAG1(LAG1(X)) is the same as LAG2(X), DIF1(DIF1(X)) is *not* the same as DIF2(X). The DIF2 function is the difference between the current period value at the point in the program where the function is executed and the final value at the end of execution two periods ago; DIF2 is not the second difference. In contrast, DIF1(DIF1(X)) is equal to DIF1(X)-LAG1(DIF1(X)), which equals $X-2*LAG1(X)+LAG2(X)$, which is the second difference of X.

More information about the differences between PROC MODEL and the DATA step LAG and DIF functions is found in Chapter 3, “Working with Time Series Data.”

Lag Lengths

The lag length of the model program is the number of lags needed for any relevant equation. The program lag length controls the number of observations used to initialize the lags.

PROC MODEL keeps track of the use of lags in the model program and automatically determines the lag length of each equation and of the model as a whole. PROC MODEL sets the program lag length to the maximum number of lags needed to compute any equation to be estimated, solved, or needed to compute any instrument variable used.

In determining the lag length, the ZLAG and ZDIF functions are treated as always having a lag length of 0. For example, if Y is computed as

```
y = lag2( x + zdif3( temp ) );
```

then Y has a lag length of 2 (regardless of how TEMP is defined). If Y is computed as

```
y = zlag2( x + dif3( temp ) );
```

then Y has a lag length of 0.

This is so that ARMA errors can be specified without causing the loss of additional observations to the lag starting phase and so that recursive lag specifications, such as moving-average error terms, can be used. Recursive lags are not permitted unless the ZLAG or ZDIF functions are used to truncate the lag length. For example, the following statement produces an error message:

```
t = a + b * lag( t );
```

The program variable T depends recursively on its own lag, and the lag length of T is therefore undefined.

In the following equation RESID.Y depends on the predicted value for the Y equation but the predicted value for the Y equation depends on the LAG of RESID.Y, and thus, the predicted value for the Y equation depends recursively on its own lag.

```
y = yhat + ma * lag( resid.y );
```

The lag length is infinite, and PROC MODEL prints an error message and stops. Since this kind of specification is allowed, the recursion must be truncated at some point. The ZLAG and ZDIF functions do this.

The following equation is valid and results in a lag length for the Y equation equal to the lag length of YHAT:

```
y = yhat + ma * zlag( resid.y );
```

Initially, the lags of RESID.Y are missing, and the ZLAG function replaces the missing residuals with 0s, their unconditional expected values.

The ZLAG0 function can be used to zero out the lag length of an expression. ZLAG0(x) returns the current period value of the expression x , if nonmissing, or else returns 0, and prevents the lag length of x from contributing to the lag length of the current statement.

Initializing Lags

At the start of each pass through the data set or BY group, the lag variables are set to missing values and an initialization is performed to fill the lags. During this phase, observations are read from the data set, and the model variables are given values from the data. If necessary, the model is executed to assign values to program variables that are used in lagging functions. The results for variables used in lag functions are saved. These observations are not included in the estimation or solution.

If, during the execution of the program for the lag starting phase, a lag function refers to lags that are missing, the lag function returns missing. Execution errors that occur while starting the lags are not reported unless requested. The modeling system automatically determines whether the program needs to be executed during the lag starting phase.

If L is the maximum lag length of any equation being fit or solved, then the first L observations are used to prime the lags. If a BY statement is used, the first L observations in the BY group are used to prime the lags. If a RANGE statement is used, the first L observations prior to the first observation requested in the RANGE statement are used to prime the lags. Therefore, there should be at least L observations in the data set.

Initial values for the lags of model variables can also be supplied in VAR, ENDOGENOUS, and EXOGENOUS statements. This feature provides initial lags of solution variables for dynamic solution when initial values for the solution variable are not available in the input data set. For example, the statement

```
var x 2 3 y 4 5 z 1;
```

feeds the initial lags exactly like these values in an input data set:

Lag	X	Y	Z
2	3	5	.
1	2	4	1

If initial values for lags are available in the input data set and initial lag values are also given in a declaration statement, the values in the VAR, ENDOGENOUS, or EXOGENOUS statements take priority.

The RANGE statement is used to control the range of observations in the input data set that are processed by PROC MODEL. In the following statement, '01jan1924' specifies the starting period of the range, and '01dec1943' specifies the ending period:

```
range date = '01jan1924'd to '01dec1943'd;
```

The observations in the data set immediately prior to the start of the range are used to initialize the lags.

Language Differences

For the most part, PROC MODEL programming statements work the same as they do in the DATA step as documented in *SAS Language: Reference*. However, there are several differences that should be noted.

DO Statement Differences

The DO statement in PROC MODEL does not allow a character index variable. Thus, the following DO statement is not valid in PROC MODEL, although it is supported in the DATA step:

```
do i = 'A', 'B', 'C'; /* invalid PROC MODEL code */
```

IF Statement Differences

The IF statement in PROC MODEL does not allow a character-valued condition. For example, the following IF statement is not supported by PROC MODEL:

```
if 'this' then statement;
```

Comparisons of character values are supported in IF statements, so the following IF statement is acceptable:

```
if 'this' < 'that' then statement;
```

PROC MODEL allows for embedded conditionals in expressions. For example the following two statements are equivalent:

```
flag = if time = 1 or time = 2 then conc+30/5 + dose*time
      else if time > 5 then (0=1) else (patient * flag);

if time = 1 or time = 2 then flag= conc+30/5 + dose*time;
else if time > 5 then flag=(0=1); else flag=patient*flag;
```

Note that the ELSE operator involves only the first object or token after it so that the following assignments are not equivalent:

```
total = if sum > 0 then sum else sum + reserve;
total = if sum > 0 then sum else (sum + reserve);
```

The first assignment makes TOTAL always equal to SUM plus RESERVE.

PUT Statement Differences

The PUT statement, mostly used in PROC MODEL for program debugging, supports only some of the features of the DATA step PUT statement. It also has some new features that the DATA step PUT statement does not support.

The PROC MODEL PUT statement does not support line pointers, factored lists, iteration factors, overprinting, the `_INFILE_` option, or the colon (`:`) format modifier.

The PROC MODEL PUT statement does support expressions, but an expression must be enclosed in parentheses. For example, the following statement prints the square root of `x`:

```
put (sqrt(x));
```

Subscripted array names must be enclosed in parentheses. For example, the following statement prints the *i*th element of the array `A`:

```
put (a i);
```

However, the following statement is an error:

```
put a i;
```

The PROC MODEL PUT statement supports the print item `_PDV_` to print a formatted listing of all the variables in the program. For example, the following statement prints a much more readable listing of the variables than does the `_ALL_` print item:

```
put _pdv_;
```

To print all the elements of the array A, use the following statement:

```
put a;
```

To print all the elements of A with each value labeled by the name of the element variable, use the following statement:

```
put a=;
```

ABORT Statement Difference

In the MODEL procedure, the ABORT statement does not allow any arguments.

SELECT/WHEN/OTHERWISE Statement Differences

The WHEN and OTHERWISE statements allow more than one target statement. That is, DO groups are not necessary for multiple statement WHENs. For example in PROC MODEL, the following syntax is valid:

```
select;
  when (exp1)
    stmt1;
    stmt2;
  when (exp2)
    stmt3;
    stmt4;
end;
```

The ARRAY Statement

```
ARRAY arrayname < {dimensions} > < $ [length] > < variables and constants > ; ;
```

The ARRAY statement is used to associate a name with a list of variables and constants. The array name can then be used with subscripts in the model program to refer to the items in the list.

In PROC MODEL, the ARRAY statement does not support all the features of the DATA step ARRAY statement. Implicit indexing cannot be used; all array references must have explicit subscript expressions. Only exact array dimensions are allowed; lower-bound specifications are not supported. A maximum of six dimensions is allowed.

On the other hand, the ARRAY statement supported by PROC MODEL does allow both variables and constants to be used as array elements. You cannot make assignments to constant array elements. Both dimension specification and the list of elements are optional, but at least one must be supplied.

When the list of elements is not given or fewer elements than the size of the array are listed, array variables are created by suffixing element numbers to the array name to complete the element list.

The following are valid PROC MODEL array statements:

```
array x[120];           /* array X of length 120           */
array q[2,2];          /* Two dimensional array Q         */
array b[4] va vb vc vd; /* B[2] = VB, B[4] = VD           */
array x x1-x30;        /* array X of length 30, X[7] = X7 */
array a[5] (1 2 3 4 5); /* array A initialized to 1,2,3,4,5 */
```

RETAIN Statement

RETAIN *variables initial-values* ;

The RETAIN statement causes a program variable to hold its value from a previous observation until the variable is reassigned. The RETAIN statement can be used to initialize program variables.

The RETAIN statement does not work for model variables, parameters, or control variables because the values of these variables are under the control of PROC MODEL and not programming statements. Use the PARMs and CONTROL statements to initialize parameters and control variables. Use the VAR, ENDOGENOUS, or EXOGENOUS statement to initialize model variables.

Storing Programs in Model Files

Models can be saved in and recalled from SAS catalog files as well as XML-based data sets. SAS catalogs are special files that can store many kinds of data structures as separate units in one SAS file. Each separate unit is called an entry, and each entry has an entry type that identifies its structure to the SAS system. Starting with SAS 9.2, model files are being stored as SAS data sets instead of being stored as members of a SAS catalog as in earlier releases. This makes MODEL files more readily extendable in the future and enables Java-based applications to read the MODEL files directly. You can choose between the two formats by specifying a global CMPMODEL option in an OPTIONS statement. Details are given below.

In general, to save a model, use the OUTMODEL=*name* option in the PROC MODEL statement, where *name* is specified as *libref.catalog.entry*, *libref.entry*, or *entry* for catalog entry and, starting with SAS 9.2, *libref.datasetname* or *datasetname* for XML-based SAS datasets. The *libref*, *catalog*, *datasetnames* and *entry* names must be valid SAS names no more than 32 characters long. The *catalog* name is restricted to seven characters on the CMS operating system. If not given, the *catalog* name defaults to MODELS, and the *libref* defaults to WORK. The entry type is always MODEL. Thus, OUTMODEL=X writes the model to the file WORK.MODELS.X.MODEL in the SAS catalog or creates a WORK.X XML-based dataset in the WORK library depending on the format chosen by using the CMPMODEL= option. By default, both these formats are chosen.

The CMPMODEL= option can be used in an OPTIONS statement to modify the behavior when reading and writing MODEL files. The values allowed are CMPMODEL= BOTH | XML | CATALOG. For example, the following statements restore the previous behavior:

```
options cmpmodel=catalog;
```

The CMPMODEL= option defaults to BOTH in SAS 9.2 and is intended for transitional use. If CMPMODEL=BOTH, the MODEL procedure writes both formats; when loading model files PROC MODEL attempts to load the XML version first and the CATALOG version second (if the XML version is not found). If CMPMODEL=XML, the MODEL procedure reads and writes only the XML format. If CMPMODEL=CATALOG, only the catalog format is used.

The MODEL= option is used to read in a model. A list of model files can be specified in the MODEL= option, and a range of names with numeric suffixes can be given, as in MODEL=(MODEL1–MODEL10). When more than one model file is given, the list must be placed in parentheses, as in MODEL=(A B C), except in case of a single name. If more than one model file is specified, the files are combined in the order listed in the MODEL= option.

The MODEL procedure continues to read and write catalog MODEL files, and model files created by previous releases of SAS/ETS continue to work, so you should experience no direct impact from this change.

When the MODEL= option is specified in the PROC MODEL statement and model definition statements are also given later in the PROC MODEL step, the model files are read in first, in the order listed, and the model program specified in the PROC MODEL step is appended after the model program read from the MODEL= files. The class assigned to a variable, when multiple model files are used, is the last declaration of that variable. For example, if Y1 was declared endogenous in the model file M1 and exogenous in the model file M2, the following statement causes Y1 to be declared exogenous.

```
proc model model=(m1 m2);
```

The INCLUDE statement can be used to append model code to the current model code. In contrast, when the MODEL= option is used in the RESET statement, the current model is deleted before the new model is read.

By default, no model file is output if the PROC MODEL step performs any FIT or SOLVE tasks, or if the MODEL= option or the NOSTORE option is used. However, to ensure compatibility with previous versions of SAS/ETS software, when the PROC MODEL step does nothing but compile the model program, no input model file is read, and the NOSTORE option is not used, a model file is written. This model file is the default input file for a later PROC SYSLIN or PROC SIMLIN step. The default output model filename in this case is WORK.MODELS._MODEL_.MODEL.

If FIT statements are used to estimate model parameters, the parameter estimates written to the output model file are the estimates from the last estimation performed for each parameter.

Diagnostics and Debugging

PROC MODEL provides several features to aid in finding errors in the model program. These debugging features are not usually needed; most models can be developed without them.

The example model program that follows is used in the following sections to illustrate the diagnostic and debugging capabilities. This example is the estimation of a segmented model.

```

/*--- Diagnostics and Debugging ---*/

Program Listing

The LIST option produces a listing of the model program. The statements are printed one per line with the original line number and column position of the statement.

The program listing from the example program is shown in [Figure 18.85](#).

Figure 18.85 LIST Output for Segmented Model

```

                                QUADRATIC MODEL WITH PLATEAU

                                The MODEL Procedure

                                Listing of Compiled Program Code
      Stmt      Line:Col      Statement as Parsed
      -----
      1      3930:4      x0 = (-0.5 * b) / c;
      2      3931:4      if x < x0 then
      3      3932:7      PRED.y = a + b * x + c * x * x;
      3      3932:7      RESID.y = PRED.y - ACTUAL.y;
      3      3932:7      ERROR.y = PRED.y - y;
      4      3933:4      else
      5      3934:7      PRED.y = a + b * x0 + c * x0 * x0;
      5      3934:7      RESID.y = PRED.y - ACTUAL.y;
      5      3934:7      ERROR.y = PRED.y - y;

```

The LIST option also shows the model translations that PROC MODEL performs. LIST output is useful for understanding the code generated by the %AR and the %MA macros.

Cross-Reference

The XREF option produces a cross-reference listing of the variables in the model program. The XREF listing is usually used in conjunction with the LIST option. The XREF listing does not include derivative (@-prefixed) variables. The XREF listing does not include generated assignments to equation variables, PRED., RESID., and ERROR.-prefixed variables, unless the DETAILS option is used.

The cross-reference from the example program is shown in [Figure 18.86](#).

Figure 18.86 XREF Output for Segmented Model

Compiler Listing

The LISTCODE option lists the model code and derivatives tables produced by the compiler. This listing is useful only for debugging and should not normally be needed.

LISTCODE prints the operator and operands of each operation generated by the compiler for each model program statement. Many of the operands are temporary variables generated by the compiler and given names such as #temp1. When derivatives are taken, the code listing includes the operations generated for the derivatives calculations. The derivatives tables are also listed.

A LISTCODE option prints the transformed equations from the example shown in Figure 18.87 and Figure 18.88.

Analyzing the Structure of Large Models

PROC MODEL provides several features to aid in analyzing the structure of the model program. These features summarize properties of the model in various forms.

The following Klein's model program is used to introduce the LISTDEP, BLOCK, and GRAPH options.

```
proc model out=m data=klein listdep graph block;
  endogenous c p w i x wsum k y;
  exogenous wp g t year;
  parms c0-c3 i0-i3 w0-w3;
  a: c = c0 + c1 * p + c2 * lag(p) + c3 * wsum;
  b: i = i0 + i1 * p + i2 * lag(p) + i3 * lag(k);
  c: w = w0 + w1 * x + w2 * lag(x) + w3 * year;
  x = c + i + g;
  y = c + i + g-t;
  p = x-w-t;
  k = lag(k) + i;
  wsum = w + wp;
  id year;
run;
```

Dependency List

The LISTDEP option produces a dependency list for each variable in the model program. For each variable, a list of variables that depend on it and a list of variables it depends on is given. The dependency list produced by the example program is shown in [Figure 18.89](#).

Figure 18.89 *continued*

BLOCK Listing

The BLOCK option prints an analysis of the program variables based on the assignments in the model program. The output produced by the example is shown in [Figure 18.90](#).

Figure 18.90 The BLOCK Output for Klein's Model

```

The MODEL Procedure
Model Structure Analysis
(Based on Assignments to Endogenous Model Variables)

Exogenous Variables      wp g t year
Endogenous Variables     c p w i x wsum k y

Block Structure of the System

Block 1      c p w i x wsum

Dependency Structure of the System

Block 1      Depends On All_Exogenous
k            Depends On Block 1 All_Exogenous
y            Depends On Block 1 All_Exogenous

```

One use for the block output is to put a model in recursive form. Simulations of the model can be done with the SEIDEL method, which is efficient if the model is recursive and if the equations are in recursive order. By examining the block output, you can determine how to reorder the model equations for the most efficient simulation.

Adjacency Graph

The GRAPH option displays the same information as the BLOCK option with the addition of an adjacency graph. An X in a column in an adjacency graph indicates that the variable associated with the row depends on the variable associated with the column. The output produced by the example is shown in [Figure 18.91](#).

The first and last graphs are straightforward. The middle graph represents the dependencies of the nonexogenous variables after transitive closure has been performed (that is, A depends on B, and B depends on C, so A depends on C). The preceding transitive closure matrix indicates that K and Y do not directly or indirectly depend on each other.

Examples: MODEL Procedure

Example 18.1: OLS Single Nonlinear Equation

This example illustrates the use of the MODEL procedure for nonlinear ordinary least squares (OLS) regression. The model is a logistic growth curve for the population of the United States. The data is the population in millions recorded at ten-year intervals starting in 1790 and ending in 2000. For an explanation of the starting values given by the `START=` option, see the section “[Troubleshooting Convergence Problems](#)” on page 1080. Portions of the output from the following statements are shown in [Output 18.1.1](#) through [Output 18.1.3](#).

```

title 'Logistic Growth Curve Model of U.S. Population';
data uspop;
  input pop :6.3 @@;

Logistic Growth Curve Model of U.S. Population						
The MODEL Procedure						
Nonlinear OLS Summary of Residual Errors						
Equation	DF Model	DF Error	SSE	MSE	R-Square	Adj R-Sq
pop	3	18	345.6	19.2020	0.9972	0.9969
Nonlinear OLS Parameter Estimates						
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t	Label	
a	387.9307	30.0404	12.91	<.0001	Maximum Population	
b	3.990385	0.0695	57.44	<.0001	Location Parameter	
c	0.022703	0.00107	21.22	<.0001	Initial Growth Rate	

The adjusted R^2 value indicates the model fits the data well. There are only 21 observations and the model is nonlinear, so significance tests on the parameters are only approximate. The significance tests and associated approximate probabilities indicate that all the parameters are significantly different from 0.

The FIT statement included the options OUT=RESID and OUTRESID so that the residuals from the estimation are saved to the data set RESID. The residuals are plotted to check for heteroscedasticity by using PROC SGPLOT as follows.

```

title2 "Residuals Plot";
proc sgplot data=resid;
  refline 0;
  scatter x=year y=pop / markerattrs=(symbol=circlefilled);
  xaxis values=(1780 to 2000 by 20);
run;

```

The plot is shown in [Output 18.1.4](#).

Output 18.1.4 Residual for Population Model (Actual–Predicted)

The residuals do not appear to be independent, and the model could be modified to explain the remaining nonrandom errors.

Example 18.2: A Consumer Demand Model

This example shows the estimation of a system of nonlinear consumer demand equations based on the translog functional form by using seemingly unrelated regression (SUR). Expenditure shares and corresponding normalized prices are given for three goods.

Since the shares add up to one, the system is singular; therefore, one equation is omitted from the estimation process. The choice of which equation to omit is arbitrary. The nonlinear system is first estimated in unrestricted form by the following statements:

```

title1 'Consumer Demand--Translog Functional Form';
title2 'Asymmetric Model';

proc model data=tlog1;
  endogenous share1 share2;
  parms a1 a2 b11 b12 b13 b21 b22 b23 b31 b32 b33;

  bm1 = b11 + b21 + b31;
  bm2 = b12 + b22 + b32;
  bm3 = b13 + b23 + b33;
  lp1 = log(p1);
  lp2 = log(p2);
  lp3 = log(p3);
  share1 = ( a1 + b11 * lp1 + b12 * lp2 + b13 * lp3 ) /
            ( -1 + bm1 * lp1 + bm2 * lp2 + bm3 * lp3 );
  share2 = ( a2 + b21 * lp1 + b22 * lp2 + b23 * lp3 ) /
            ( -1 + bm1 * lp1 + bm2 * lp2 + bm3 * lp3 );

  fit share1 share2
  start=( a1 -.14 a2 -.45 b11 .03 b12 .47 b22 .98 b31 .20
          b32 1.11 b33 .71 ) / outsused=smatrix sur;
run;

```

A portion of the printed output produced by this example is shown in [Output 18.2.1](#) through [Output 18.2.3](#).

```

Hypothesis testing requires that the **S** matrix from the unrestricted model be imposed on the restricted model, as explained in the section “[Tests on Parameters](#)” on page 1128. The **S** matrix saved in the data set **SMATRIX** is requested by the **SDATA=** option. A chi-square test is used to see if the hypothesis of symmetry is accepted or rejected. $(Oc - Ou)$ has a chi-square distribution asymptotically, where Oc is the constrained **OBJECTIVE*N** and Ou is the unconstrained **OBJECTIVE*N**. The degrees of freedom is equal to the difference in the number of free parameters in the two models.

In this example, O_u is 76.9697 and O_c is 78.4097, resulting in a difference of 1.44 with 3 degrees of freedom. You can obtain the probability value by using the following statements:

```
data _null_;
  /* probchi( reduced-full, n-restrictions )*/
  p = 1-probchi( 1.44, 3 );
  put p=;
run;
```

The output from this DATA step run is $p = 0.6961858724$. With this p -value you cannot reject the hypothesis of symmetry. This test is asymptotically valid.

Example 18.3: Vector AR(1) Estimation

This example shows the estimation of a two-variable vector AR(1) error process for the Grunfeld model (Grunfeld and Griliches 1960) by using the %AR macro. First, the full model is estimated. Second, the model is estimated with the restriction that the errors are univariate AR(1) instead of a vector process. The following statements produce [Output 18.3.1](#) through [Output 18.3.5](#).

```
data grunfeld;
  input year gei gef gec whi whf whc;
  label gei = 'Gross Investment GE'
        gec = 'Capital Stock Lagged GE'
        gef = 'Value of Outstanding Shares GE Lagged'
        whi = 'Gross Investment WH'
        whc = 'Capital Stock Lagged WH'
        whf = 'Value of Outstanding Shares Lagged WH';
datalines;
1935    33.1      1170.6    97.8      12.93     191.5     1.8
1936    45.0      2015.8   104.4     25.90     516.0     .8
... more lines ...

title1 'Example of Vector AR(1) Error Process Using Grunfeld's Model';
/* Note: GE stands for General Electric
        WH stands for Westinghouse      */

proc model outmodel=grunmod;
  var gei whi gef gec whf whc;
  parms ge_int ge_f ge_c wh_int wh_f wh_c;
  label ge_int = 'GE Intercept'
        ge_f   = 'GE Lagged Share Value Coef'
        ge_c   = 'GE Lagged Capital Stock Coef'
        wh_int = 'WH Intercept'
        wh_f   = 'WH Lagged Share Value Coef'
        wh_c   = 'WH Lagged Capital Stock Coef';
  gei = ge_int + ge_f * gef + ge_c * gec;
  whi = wh_int + wh_f * whf + wh_c * whc;
run;
```

The preceding PROC MODEL step defines the structural model and stores it in the model file named GRUNMOD.

The following PROC MODEL step reads in the model, adds the vector autoregressive terms using %AR, and requests SUR estimation by using the FIT statement.

```

title2 'With Unrestricted Vector AR(1) Error Process';

proc model data=grunfeld model=grunmod;
  %ar( ar, 1, gei whi )
  fit gei whi / sur;
run;

```

The final PROC MODEL step estimates the restricted model, as shown in the following statements:

```

title2 'With restricted AR(1) Error Process';

proc model data=grunfeld model=grunmod;
  %ar( gei, 1 )
  %ar( whi, 1 )
  fit gei whi / sur;
run;

```

Example 18.4: MA(1) Estimation

This example estimates parameters for an MA(1) error process for the Grunfeld model, using both the unconditional least squares and the maximum likelihood methods. The ARIMA procedure estimates for Westinghouse equation are shown for comparison. The output of the following statements is summarized in [Output 18.4.1](#):

```
proc model outmodel=grunmod;
  var gei whi gef gec whf whc;
  parms ge_int ge_f ge_c wh_int wh_f wh_c;
  label ge_int = 'GE Intercept'
        ge_f   = 'GE Lagged Share Value Coef'
        ge_c   = 'GE Lagged Capital Stock Coef'
        wh_int = 'WH Intercept'
        wh_f   = 'WH Lagged Share Value Coef'
        wh_c   = 'WH Lagged Capital Stock Coef';
```

```

    gei = ge_int + ge_f * gef + ge_c * gec;
    whi = wh_int + wh_f * whf + wh_c * whc;
run;

The model stored in [Example 18.3](#) is read in by using the MODEL= option and the moving-average terms are added using the %MA macro.

The MA(1) model using maximum likelihood is estimated by using the following statements:

```

title2 'MA(1) Error Process Using Maximum Likelihood ';

proc model data=grunfeld model=grunmod;
  %ma(gei,1, m=ml);
  %ma(whi,1, m=ml);
  fit whi gei;
run;

```

For comparison, the model is estimated by using PROC ARIMA as follows:

```

title2 'PROC ARIMA Using Maximum Likelihood ';

proc arima data=grunfeld;
  identify var=whi cross=(whf whc) noprint;
  estimate q=1 input=(whf whc) method=ml;
run;

```

PROC ARIMA does not estimate systems, so only one equation is evaluated. The estimation results are shown in [Output 18.4.3](#) and [Output 18.4.4](#). The small differences in the parameter values between PROC MODEL and PROC ARIMA can be eliminated by tightening the convergence criteria for both procedures.

Example 18.5: Polynomial Distributed Lags by Using %PDL

This example shows the use of the %PDL macro for polynomial distributed lag models. Simulated data is generated so that Y is a linear function of six lags of X, with the lag coefficients following a quadratic polynomial. The model is estimated by using a fourth-degree polynomial, both with and without endpoint constraints. The example uses simulated data generated from the following model:

$$y_t = 10 + \sum_{z=0}^6 f(z)x_{t-z} + \epsilon$$

$$f(z) = -5z^2 + 1.5z$$

The LIST option prints the model statements added by the %PDL macro. The following statements generate simulated data as shown:

```

/*-----*/
/*  Generate Simulated Data for a Linear Model with a PDL on X  */
/*      y = 10 + x(6,2) + e                                     */
/*      pdl(x) = -5.*(lg)**2 + 1.5*(lg) + 0.                  */
/*-----*/
data pdl;
  pdl2=-5.; pdl1=1.5; pdl0=0;
  array zz(i) z0-z6;
  do i=1 to 7;
    z=i-1;
    zz=pdl2*z**2 + pdl1*z + pdl0;
  end;
  do n=-11 to 30;
    x =10*ranuni(1234567)-5;
    pdl=z0*x + z1*x11 + z2*x12 + z3*x13 + z4*x14 + z5*x15 + z6*x16;
    e =10*rannor(1234567);
    y =10+pdl+e;
    if n>=1 then output;
    x16=x15; x15=x14; x14=x13; x13=x12; x12=x11; x11=x;
  end;
run;

title1 'Polynomial Distributed Lag Example';
title3 'Estimation of PDL(6,4) Model-- No Endpoint Restrictions';

```

```

proc model data=pdl;
  parms int;                               /* declare the intercept parameter */
  %pdl( xpdl, 6, 4 )                        /* declare the lag distribution */
  y = int + %pdl( xpdl, x );                /* define the model equation */
  fit y / list;                             /* estimate the parameters */
run;

```

The LIST output for the model without endpoint restrictions is shown in [Output 18.5.1](#). The first seven statements in the generated program are the polynomial expressions for lag parameters XPDL_L0 through XPDL_L6. The estimated parameters are INT, XPDL_0, XPDL_1, XPDL_2, XPDL_3, and XPDL_4.

Output 18.5.1 PROC MODEL Listing of Generated Program

Example 18.6: General Form Equations

Data for this example are generated. General form equations are estimated and forecast by using PROC MODEL. The system is a basic supply and demand model.

The following statements specify the form of the model:

```

title1 "General Form Equations for Supply-Demand Model";

proc model outmodel=model;
  var price quantity income unitcost;
  parms d0-d2 s0-s2;
  eq.demand=d0+d1*price+d2*income-quantity;
  eq.supply=s0+s1*price+s2*unitcost-quantity;
run;

```

Three data sets are used in this example. The first data set, HISTORY, is used to estimate the parameters of the model. The ASSUME data set is used to produce a forecast of PRICE and QUANTITY. Notice that the ASSUME data set does not need to contain the variables PRICE and QUANTITY. The HISTORY data set is shown as follows:

```

data history;
  input year income unitcost price quantity;
datalines;
1976 2221.87 3.31220 0.17903 266.714

```

```

1977    2254.77    3.61647    0.06757    276.049
... more lines ...

```

The ASSUME data set is shown as follows:

```

data assume;
  input year income unitcost;
datalines;
1986    2571.87    2.31220
1987    2609.12    2.45633
1988    2639.77    2.51647
1989    2667.77    1.65617
1990    2705.16    1.01601
;

```

The third data set, GOAL, used in a forecast of PRICE and UNITCOST as a function of INCOME and QUANTITY is as follows:

```

data goal;
  input year income quantity;
datalines;
1986    2571.87    371.4
1987    2721.08    416.5
1988    3327.05    597.3
1989    3885.85    764.1
1990    3650.98    694.3

Example 18.7: Spring and Damper Continuous System

This model simulates the mechanical behavior of a spring and damper system shown in Figure 18.92.

Figure 18.92 Spring and Damper System Model

A mass is hung from a spring with spring constant K . The motion is slowed by a damper with damper constant C . The damping force is proportional to the velocity, while the spring force is proportional to the displacement.

This is actually a continuous system; however, the behavior can be approximated by a discrete time model. We approximate the differential equation

$$\frac{\partial \text{disp}}{\partial \text{time}} = \text{velocity}$$

with the difference equation

$$\frac{\Delta \text{disp}}{\Delta \text{time}} = \text{velocity}$$

This is rewritten as

$$\frac{\text{disp} - \text{LAG}(\text{disp})}{dt} = \text{velocity}$$

where dt is the time step used. In PROC MODEL, this is expressed with the program statement

```
disp = lag(disp) + vel * dt;
```

or

```
dert.disp = vel;
```

The first statement is simply a computing formula for Euler's approximation for the integral

$$\text{disp} = \int \text{velocity} dt$$

If the time step is small enough with respect to the changes in the system, the approximation is good. Although PROC MODEL does not have the variable step-size and error-monitoring features of simulators designed for continuous systems, the procedure is a good tool to use for less challenging continuous models.

The second form instructs the MODEL procedure to do the integration for you.

This model is unusual because there are no exogenous variables, and endogenous data are not needed. Although you still need a SAS data set to count the simulation periods, no actual data are brought in.

Since the variables DISP and VEL are lagged, initial values specified in the VAR statement determine the starting state of the system. The mass, time step, spring constant, and damper constant are declared and initialized by a CONTROL statement as shown in the following statements:

```
title1 'Simulation of Spring-Mass-Damper System';

/*- Data to drive the simulation time periods ---*/
data one;
  do n=1 to 100;
    output;
  end;
run;

proc model data=one outmodel=spring;
  var      force -200 disp 10 vel 0 accel -20 time 0;
  control  mass  9.2 c    1.5 dt .1 k      20;
  force = -k * disp -c * vel;
  disp  = lag(disp) + vel * dt;
```

```

    vel  = lag(vel) + accel * dt;
    accel = force / mass;
    time = lag(time) + dt;
run;

```

The displacement scale is zeroed at the point where the force of gravity is offset, so the acceleration of the gravity constant is omitted from the force equation. The control variable C and K represent the damper and the spring constants respectively.

The model is simulated three times, and the simulation results are written to output data sets. The first run uses the original initial conditions specified in the VAR statement. In the second run, the initial displacement is doubled; the results show that the period of the motion is unaffected by the amplitude. In the third run, the DERT. syntax is used to do the integration. Notice that the path of the displacement is close to the old path, indicating that the original time step is short enough to yield an accurate solution. These simulations are performed by the following statements:

```

proc model data=one model=spring;
  title2 "Simulation of the model for the base case";
  control run '1';
  solve / out=a;
run;

  title2 "Simulation of the model with twice the initial displacement";
  control run '2';
  var disp 20;
  solve / out=b;
run;

data two;
  do time = 0 to 10 by .2; output;end;
run;

title2 "Simulation of the model using the dert. syntax";
proc model data=two;
  var      force -200  disp  10  vel  0  accel -20  time 0;
  control  mass   9.2  c    1.5  dt   .1  k      20;
  control run '3' ;
  force = -k * disp -c * vel;
  dert.disp = vel ;
  dert.vel  = accel;
  accel = force / mass;
  solve / out=c;
  id time ;
run;

```

The output SAS data sets that contain the solution results are merged and the displacement time paths for the three simulations are plotted. The three runs are identified on the plot as 1, 2, and 3. The following statements produce [Output 18.7.1](#) through [Output 18.7.5](#).

```

data p;
  set a b c;
run;

```

```

title2 'Overlay Plot of All Three Simulations';
proc sgplot data=p;

Example 18.8: Nonlinear FIML Estimation

The data and model for this example were obtained from Bard (1974, p.133–138). The example is a two-equation econometric model used by Bodkin and Klein to fit U.S production data for the years 1909–1949. The model is the following:

$$g_1 = c_1 10^{c_2 z_4} (c_5 z_1^{-c_4} + (1 - c_5) z_2^{-c_4})^{-c_3/c_4} - z_3 = 0$$

$$g_2 = [c_5 / (1 - c_5)] (z_1 / z_2)^{(-1 - c_4)} - z_5 = 0$$

where z_1 is capital input, z_2 is labor input, z_3 is real output, z_4 is time in years with 1929 as year zero, and z_5 is the ratio of price of capital services to wage scale. The c_i 's are the unknown parameters. z_1 and z_2 are considered endogenous variables. A FIML estimation is performed by using the following statements:

```

data bodkin;
  input z1 z2 z3 z4 z5;
datalines;
1.33135 0.64629 0.4026 -20 0.24447
1.39235 0.66302 0.4084 -19 0.23454

... more lines ...

title1 "Nonlinear FIML Estimation";

proc model data=bodkin;
  parms c1-c5;
  endogenous z1 z2;
  exogenous z3 z4 z5;

  eq.g1 = c1 * 10 ** (c2 * z4) * (c5*z1**(-c4)+
    (1-c5)*z2**(-c4))**(-c3/c4) - z3;
  eq.g2 = (c5/(1-c5))*(z1/z2)**(-1-c4) -z5;

  fit g1 g2 / fiml ;
run;

```

When FIML estimation is selected, the log likelihood of the system is output as the objective value. The results of the estimation are shown in [Output 18.8.1](#).

Example 18.9: Circuit Estimation

Consider the nonlinear circuit shown in Figure 18.93.

Figure 18.93 Nonlinear Resistor Capacitor Circuit

The theory of electric circuits is governed by Kirchhoff's laws: the sum of the currents flowing to a node is zero, and the net voltage drop around a closed loop is zero. In addition to Kirchhoff's laws, there are relationships between the current I through each element and the voltage drop V across the elements. For the circuit in Figure 18.93, the relationships are

$$C \frac{dV}{dt} = I$$

for the capacitor and

$$V = (R_1 + R_2(1 - \exp(-V)))I$$

for the nonlinear resistor. The following differential equation describes the current at node 2 as a function of time and voltage for this circuit:

$$C \frac{dV_2}{dt} - \frac{V_1 - V_2}{R_1 + R_2(1 - \exp(-V))} = 0$$

This equation can be written in the form

$$\frac{dV_2}{dt} = \frac{V_1 - V_2}{(R_1 + R_2(1 - \exp(-V)))C}$$

Consider the following data.

```

data circ;
  input v2 v1 time@@;
datalines;
-0.00007 0.0 0.0000000001 0.00912 0.5 0.0000000002
 0.03091 1.0 0.0000000003 0.06419 1.5 0.0000000004
 0.11019 2.0 0.0000000005 0.16398 2.5 0.0000000006
 0.23048 3.0 0.0000000007 0.30529 3.5 0.0000000008
 0.39394 4.0 0.0000000009 0.49121 4.5 0.0000000010
 0.59476 5.0 0.0000000011 0.70285 5.0 0.0000000012
 0.81315 5.0 0.0000000013 0.90929 5.0 0.0000000014

 1.40461 5.0 0.0000000019 1.48624 5.0 0.0000000020
 1.57894 5.0 0.0000000021 1.66471 5.0 0.0000000022
;

```

You can estimate the parameters in the preceding equation by using the following SAS statements:

```

title1 'Circuit Model Estimation Example';

proc model data=circ mintimestep=1.0e-23;
  parm R2 2000 R1 4000 C 5.0e-13;
  dert.v2 = (v1-v2)/((r1 + r2*(1-exp( -(v1-v2)))) * C);
  fit v2;
run;

```

The results of the estimation are shown in [Output 18.9.1](#).

Output 18.9.1 Circuit Estimation

Circuit Model Estimation Example				
The MODEL Procedure				
Nonlinear OLS Parameter Estimates				
Parameter	Estimate	Approx Std Err	t Value	Approx Pr > t
R2	3002.471	1517.1	<-----	Biased
R1	4984.842	1466.8	<-----	Biased
C	5E-13	0	<-----	Biased

NOTE: The model was singular. Some estimates are marked 'Biased'.

In this case, the model equation is such that there is linear dependency that causes biased results and inflated variances. The Jacobian matrix is singular or nearly singular, but eliminating one of the parameters is not a solution in this case.

Example 18.10: Systems of Differential Equations

The following is a simplified reaction scheme for the competitive inhibitors with recombinant human renin (Morelock et al. 1995).

Figure 18.94 Competitive Inhibition of Recombinant Human Renin

In Figure 18.94, E =enzyme, D =probe, and I =inhibitor.

The differential equations that describe this reaction scheme are as follows:

$$\frac{dD}{dt} = k_{1r} * ED - k_{1f} * E * D$$

$$\frac{dED}{dt} = k_{1f} * E * D - k_{1r} * ED$$

$$\frac{dE}{dt} = k_{1r} * ED - k_{1f} * E * D + k_{2r} * EI - k_{2f} * E * I$$

$$\frac{dEI}{dt} = k_{2f} * E * I - k_{2r} * EI$$

$$\frac{dI}{dt} = k_{2r} * EI - k_{2f} * E * I$$

For this system, the initial values for the concentrations are derived from equilibrium considerations (as a function of parameters) or are provided as known values.

The experiment used to collect the data was carried out in two ways; preincubation (type='disassoc') and no preincubation (type='assoc'). The data also contain repeated measurements. The data contain

values for fluorescence F , which is a function of concentration. Since there are no direct data for the concentrations, all the differential equations are simulated dynamically.

The SAS statements used to fit this model are as follows:

```

Example 18.11: Monte Carlo Simulation

This example illustrates how the form of the error in a ODE model affects the results from a static and dynamic estimation. The differential equation studied is

$$\frac{dy}{dt} = a - ay$$

The analytical solution to this differential equation is

$$y = 1 - \exp(-at)$$

The first data set contains errors that are strictly additive and independent. The data for this estimation are generated by the following DATA step:

```
data drive1;
  a = 0.5;
  do iter=1 to 100;
    do time = 0 to 50;
      y = 1 - exp(-a*time) + 0.1 *rannor(123);
      output;
    end;
  end;
run;
```

The second data set contains errors that are cumulative in form.

```
data drive2;
  a = 0.5;
  yp = 1.0 + 0.01 *rannor(123);
  do iter=1 to 100;
    do time = 0 to 50;
      y = 1 - exp(-a)*(1 - yp);
      yp = y + 0.01 *rannor(123);
      output;
    end;
  end;
run;
```

The following statements perform the 100 static estimations for each data set:

```

title1 'Monte Carlo Simulation of ODE';

proc model data=drive1 noprint;
  parm a 0.5;
  dert.y = a - a * y;
  fit y / outest=est;
  by iter;
run;

```

Similar statements are used to produce 100 dynamic estimations with a fixed and an unknown initial value. The first value in the data set is used to simulate an error in the initial value. The following PROC UNIVARIATE statements process the estimations:

```

proc univariate data=est noprint;
  var a;
  output out=monte mean=mean p5=p5 p95=p95;
run;

proc print data=monte;
run;

```

The results of these estimations are summarized in [Table 18.6](#).

Table 18.6 Monte Carlo Summary, A=0.5

Estimation Type	Additive Error			Cumulative Error		
	mean	p95	p5	mean	p95	p5
static	0.77885	1.03524	0.54733	0.57863	1.16112	0.31334
dynamic fixed	0.48785	0.63273	0.37644	3.8546E24	8.88E10	-51.9249
dynamic unknown	0.48518	0.62452	0.36754	641704.51	1940.42	-25.6054

For this example model, it is evident that the static estimation is the least sensitive to misspecification.

Example 18.12: Cauchy Distribution Estimation

In this example a nonlinear model is estimated by using the Cauchy distribution. Then a simulation is done for one observation in the data.

The following DATA step creates the data for the model.

```

/* Generate a Cauchy distributed Y */
data c;
  format date monyy.;
  call streaminit(156789);
  do t=0 to 20 by 0.1;
    date=intnx('month', '01jun90'd, (t*10)-1);
    x=rand('normal');

```

```

        e=rand('cauchy') + 10 ;
        y=exp(4*x)+e;
        output;
    end;
run;

```

The model to be estimated is

$$y = e^{-ax} + \epsilon$$

$$\epsilon \sim \text{Cauchy}(nc)$$

That is, the residuals of the model are distributed as a Cauchy distribution with noncentrality parameter nc .

The log likelihood for the Cauchy distribution is

$$like = -\log(1 + (x - nc)^2 * \pi)$$

The following SAS statements specify the model and the log-likelihood function.

```

title1 'Cauchy Distribution';

proc model data=c ;
    dependent y;
    parm a -2 nc 4;
    y=exp(-a*x);

    /* Likelihood function for the residuals */
    obj = log(1+(-resid.y-nc)**2 * 3.1415926);

    errormodel y ~ general(obj) cdf=cauchy(nc);

    fit y / outsn=s1 method=marquardt;
    solve y / sdata=s1 data=c(obs=1) random=1000
            seed=256789 out=out1;
run;

title 'Distribution of Y';
proc sgplot data=out1;
    histogram y;
run;

```

The FIT statement uses the OUTSN= option to output the Σ matrix for residuals from the normal distribution. The Σ matrix is 1×1 and has value 1.0 because it is a correlation matrix. The OUTS= matrix is the scalar 2989.0. Because the distribution is univariate (no covariances), the OUTS= option would produce the same simulation results. The simulation is performed by using the SOLVE statement.

The distribution of y is shown in the following output.

Output 18.12.1 Distribution of Y

Example 18.13: Switching Regression Example

Take the usual linear regression problem

$$y = \mathbf{X}\beta + u$$

where Y denotes the n column vector of the dependent variable, \mathbf{X} denotes the $(n \times k)$ matrix of independent variables, β denotes the k column vector of coefficients to be estimated, n denotes the number of observations ($i=1, 2, \dots, n$), and k denotes the number of independent variables.

You can take this basic equation and split it into two regimes, where the i th observation on y is generated by one regime or the other:

$$y_i = \sum_{j=1}^k \beta_{1j} X_{ji} + u_{1i} = x_i' \beta_1 + u_{1i}$$

$$y_i = \sum_{j=1}^k \beta_{2j} X_{ji} + u_{2i} = x_i' \beta_2 + u_{2i}$$

where x_{hi} and x_{hj} are the i th and j th observations, respectively, on x_h . The errors, u_{1i} and u_{2i} , are assumed to be distributed normally and independently with mean zero and constant variance. The variance for the first regime is σ_1^2 , and the variance for the second regime is σ_2^2 . If $\sigma_1^2 \neq \sigma_2^2$ and $\beta_1 \neq \beta_2$, the regression system given previously is thought to be switching between the two regimes.

The problem is to estimate β_1 , β_2 , σ_1 , and σ_2 without knowing *a priori* which of the n values of the dependent variable, y , was generated by which regime. If it is known *a priori* which observations belong to which regime, a simple Chow test can be used to test $\sigma_1^2 = \sigma_2^2$ and $\beta_1 = \beta_2$.

Using Goldfeld and Quandt's D-method for switching regression, you can solve this problem. Assume that observations exist on some exogenous variables z_{1i} , z_{2i} , \dots , z_{pi} , where z determines whether the i th observation is generated from one equation or the other. The equations are given as follows:

$$y_i = x_i' \beta_1 + u_{1i} \quad \text{if } \sum_{j=1}^p \pi_j z_{ji} \leq 0$$

$$y_i = x_i' \beta_2 + u_{2i} \quad \text{if } \sum_{j=1}^p \pi_j z_{ji} > 0$$

where π_j are unknown coefficients to be estimated. Define $d(z_i)$ as a continuous approximation to a step function. Replacing the unit step function with a continuous approximation by using the cumulative normal integral enables a more practical method that produces consistent estimates.

$$d(z_i) = \frac{1}{\sqrt{2\pi}\sigma} \int_{-\infty}^{\sum \pi_j z_{ji}} \exp\left[-\frac{1}{2} \frac{\xi^2}{\sigma^2}\right] d\xi$$

\mathbf{D} is the n dimensional diagonal matrix consisting of $d(z_i)$:

$$\mathbf{D} = \begin{bmatrix} d(z_1) & 0 & 0 & 0 \\ 0 & d(z_2) & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & d(z_n) \end{bmatrix}$$

The parameters to estimate are now the k β_1 's, the k β_2 's, σ_1^2 , σ_2^2 , p π 's, and the σ introduced in the $d(z_i)$ equation. The σ can be considered as given *a priori*, or it can be estimated, in which case, the

estimated magnitude provides an estimate of the success in discriminating between the two regimes (Goldfeld and Quandt 1976). Given the preceding equations, the model can be written as:

$$Y = (\mathbf{I} - \mathbf{D})\mathbf{X}\beta_1 + \mathbf{D}\mathbf{X}\beta_2 + W$$

where $W = (\mathbf{I} - \mathbf{D})U_1 + \mathbf{D}U_2$, and W is a vector of unobservable and heteroscedastic error terms. The covariance matrix of W is denoted by $\mathbf{\Omega}$, where $\mathbf{\Omega} = (\mathbf{I} - \mathbf{D})^2\sigma_1^2 + \mathbf{D}^2\sigma_2^2$. The maximum likelihood parameter estimates maximize the following log-likelihood function.

$$\begin{aligned} \log L = & -\frac{n}{2} \log 2\pi - \frac{1}{2} \log |\mathbf{\Omega}| - \\ & \frac{1}{2} * [[Y - (\mathbf{I} - \mathbf{D})\mathbf{X}\beta_1 - \mathbf{D}\mathbf{X}\beta_2]' \mathbf{\Omega}^{-1} [Y - (\mathbf{I} - \mathbf{D})\mathbf{X}\beta_1 - \mathbf{D}\mathbf{X}\beta_2]] \end{aligned}$$

As an example, you now can use this switching regression likelihood to develop a model of housing starts as a function of changes in mortgage interest rates. The data for this example are from the U.S. Census Bureau and cover the period from January 1973 to March 1999. The hypothesis is that there are different coefficients on your model based on whether the interest rates are going up or down.

So the model for z_i is

$$z_i = p * (\text{rate}_i - \text{rate}_{i-1})$$

where rate_i is the mortgage interest rate at time i and p is a scale parameter to be estimated.

The regression model is

$$\begin{aligned} \text{starts}_i &= \text{intercept}_1 + \text{ar1} * \text{starts}_{i-1} + \text{djf1} * \text{decjanfeb} & z_i < 0 \\ \text{starts}_i &= \text{intercept}_2 + \text{ar2} * \text{starts}_{i-1} + \text{djf2} * \text{decjanfeb} & z_i \geq 0 \end{aligned}$$

where starts_i is the number of housing starts at month i and decjanfeb is a dummy variable that indicates that the current month is one of December, January, or February.

This model is written by using the following SAS statements:

```

title1 'Switching Regression Example';

proc model data=switch;
  parms sig1=10 sig2=10 int1 b11 b13 int2 b21 b23 p;
  bounds 0.0001 < sig1 sig2;

  decjanfeb = ( month(date) = 12 | month(date) <= 2 );

  a = p*dif(rate);          /* Upper bound of integral */
  d = probnorm(a);        /* Normal CDF as an approx of switch */

  /* Regime 1 */
  y1 = int1 + zlag(starts)*b11 + decjanfeb *b13 ;
  /* Regime 2 */
  y2 = int2 + zlag(starts)*b21 + decjanfeb *b23 ;
  /* Composite regression equation */

```

```

starts = (1 - d)*y1 + d*y2;

/* Resulting log-likelihood function */
logL = (1/2)* ( log(2*3.1415) ) +
      log( (sig1**2)*((1-d)**2)+(sig2**2)*(d**2) )
      + (resid.starts*( 1/( (sig1**2)*((1-d)**2)+
      (sig2**2)*(d**2) ) )*resid.starts) ) ;

errormodel starts ~ general(logL);

fit starts / method=marquardt converge=1.0e-5;

/* Test for significant differences in the parms */
test int1 = int2 ,/ lm;
test b11 = b21 ,/ lm;
test b13 = b23 ,/ lm;
test sig1 = sig2 ,/ lm;

run;

```

Four TEST statements are added to test the hypothesis that the parameters are the same in both regimes. The parameter estimates and ANOVA table from this run are shown in [Output 18.13.1](#).

Output 18.13.1 Parameter Estimates from the Switching Regression

Switching Regression Example						
The MODEL Procedure

Example 18.14: Simulating from a Mixture of Distributions

This example illustrates how to perform a multivariate simulation by using models that have different error distributions. Three models are used. The first model has t distributed errors. The second model is a GARCH(1,1) model with normally distributed errors. The third model has a noncentral Cauchy distribution.

The following SAS statements generate the data for this example. The t and the CAUCHY data sets use a common seed so that those two series are correlated.

```

/* set distribution parameters */
%let df = 7.5;
%let sig1 = .5;
%let var2 = 2.5;

data t;
  format date monyy.;
  do date='1jun2001'd to '1nov2002'd;
    /* t-distribution with df,sig1 */
    t = .05 * date + 5000 + &sig1*tinv(ranuni(1234),&df);
    output;
  end;
run;

data normal;
  format date monyy.;
  le = &var2;
  lv = &var2;
  do date='1jun2001'd to '1nov2002'd;
    /* Normal with GARCH error structure */
    v = 0.0001 + 0.2 * le**2 + .75 * lv;
    e = sqrt(v) * rannor(12345) ;
    normal = 25 + e;
    le = e;
    lv = v;
    output;
  end;
run;

```

```

data cauchy;
  format date monyy.;
  PI = 3.1415926;
  do date='1jun2001'd to '1nov2002'd;
    cauchy = -4 + tan((ranuni(1234) - 0.5) * PI);
    output;
  end;
run;

```

Since the multivariate joint likelihood is unknown, the models must be estimated separately. The residuals for each model are saved by using the OUT= option. Also, each model is saved by using the OUTMODEL= option. The ID statement is used to provide a variable in the residual data set to merge by. The XLAG function is used to model the GARCH(1,1) process. The XLAG function returns the lag of the first argument if it is nonmissing, otherwise it returns the second argument.

```

title1 't-distributed Errors Example';

proc model data=t outmod=tModel;
  parms df 10 vt 4;
  t = a * date + c;
  errormodel t ~ t( vt, df );
  fit t / out=tresid;
  id date;
run;

title1 'GARCH-distributed Errors Example';

proc model data=normal outmodel=normalModel;
  normal = b0 ;
  h.normal = arch0 + arch1 * xlag(resid.normal **2 , mse.normal)
    + GARCH1 * xlag(h.normal, mse.normal);

  fit normal /fiml out=nresid;
  id date;
run;

title1 'Cauchy-distributed Errors Example';

proc model data=cauchy outmod=cauchyModel;
  parms nc = 1;
  /* nc is noncentrality parm to Cauchy dist */
  cauchy = nc;
  obj = log(1+resid.cauchy**2 * 3.1415926);
  errormodel cauchy ~ general(obj) cdf=cauchy(nc);

  fit cauchy / out=cresid;
  id date;
run;

```

The simulation requires a covariance matrix created from normal residuals. The following DATA step statements use the inverse CDFs of the t and Cauchy distributions to convert the residuals to the normal distribution. The CORR procedure is used to create a correlation matrix that uses the converted residuals.

```
/* Merge and normalize the 3 residual data sets */
data c; merge tresid nresid cresid; by date;
    t = probit(cdf("T", t/sqrt(0.2789), 16.58 ));
    cauchy = probit(cdf("CAUCHY", cauchy, -4.0623));
run;

proc corr data=c out=s;
    var t normal cauchy;
run;
```

Now the models can be simulated together by using the MODEL procedure SOLVE statement. The data set created by the CORR procedure is used as the correlation matrix.

```
title1 'Simulating Equations with Different Error Distributions';

/* Create one observation driver data set */
data sim; merge t normal cauchy; by date;
data sim; set sim(firstobs = 519 );

proc model data=sim model=( tModel normalModel cauchyModel );
    errormodel t ~ t( vt, df );
    errormodel cauchy ~ cauchy(nc);
    solve t cauchy normal / random=2000 seed=1962 out=monte
        sdata=s(where=( _type_="CORR" ));
run;
```

An estimation of the joint density of the t and Cauchy distribution is created by using the KDE procedure. Bounds are placed on the Cauchy dimension because of its fat tail behavior. The joint PDF is shown in [Output 18.14.1](#).

```
title "T and Cauchy Distribution";

proc kde data=monte;
    univar t / out=t_dens;
    univar cauchy / out=cauchy_dens;
    bivar t cauchy / out=density
        plots=all;
run;
```

Output 18.14.1 Bivariate Density of t and Cauchy, Distribution of t by Cauchy

Example 18.15: Simulated Method of Moments—Simple Linear Regression

This example illustrates how to use SMM to estimate a simple linear regression model for the following process:

$$y = a + bx + \epsilon, \epsilon \sim iid N(0, s^2)$$

In the following SAS statements, *ysim* is simulated, and the first moment and the second moment of *ysim* are compared with those of the observed endogenous variable *y*.

```
title "Simple regression model";

data regdata;
```

```

do i=1 to 500;
  x = rannor( 1013 );
  Y = 2 + 1.5 * x + 1.5 * rannor( 1013 );
  output;
end;
run;

proc model data=regdata;
  parms a b s;
  instrument x;

  ysim = (a+b*x) + s * rannor( 8003 );
  y = ysim;
  eq.ysq = y*y - ysim*ysim;

  fit y ysq / gmm ndraw;
  bound s > 0;
run;

```

Alternatively, the MOMENT statement can be used to specify the moments using the following syntax:

```

proc model data=regdata;
  parms a b s;
  instrument x;

  ysim = (a+b*x) + s * rannor( 8003 );
  y = ysim;
  moment y = (2);

  fit y / gmm ndraw;
  bound s > 0;
run;

```

The output of the MODEL procedure is shown in [Output 18.15.1](#):

Output 18.15.1 PROC MODEL Output

Example 18.16: Simulated Method of Moments—AR(1) Process

This example illustrates how to use SMM to estimate an AR(1) regression model for the following process:

$$\begin{aligned}
 y_t &= a + bx_t + u_t \\
 u_t &= \alpha u_{t-1} + \epsilon_t \\
 \epsilon_t &\sim iid N(0, s^2)
 \end{aligned}$$

In the following SAS statements, *ysim* is simulated by using this model, and the endogenous variable *y* is set to be equal to *ysim*. The `MOMENT` statement creates two more moments for the estimation. One is the second moment, and the other is the first-order autocovariance. The `NPREOBS=10` option instructs `PROC MODEL` to run the simulation 10 times before *ysim* is compared to the first observation of *y*. Because the initial `zlag(u)` is zero, the first *ysim* is $a + b * x + s * \text{rannor}(8003)$. Without the `NPREOBS` option, this *ysim* is matched with the first observation of *y*. With `NPREOBS`, this *ysim* and the next nine *ysim* are thrown away, and the moment match starts with the eleventh *ysim* with the first observation of *y*. This way, the initial values do not exert a large influence on the simulated endogenous variables.

```

%let nobs=500;
data ardata;
  lu =0;
  do i=-10 to &nobs;
    x = rannor( 1011 );

Example 18.17: Simulated Method of Moments—Stochastic Volatility Model

This example illustrates how to use SMM to estimate a stochastic volatility model as in Andersen and Sorensen (1996):

$$\begin{aligned}y_t &= \sigma_t z_t \\ \log(\sigma_t^2) &= a + b \log(\sigma_{t-1}^2) + s u_t \\ (z_t, u_t) &\sim iid N(0, I_2)\end{aligned}$$

This model is widely used in modeling the return process of stock prices and foreign exchange rates. This is called the stochastic volatility model because the volatility is stochastic as the random variable u_t appears in the volatility equation. The following SAS statements use three moments: absolute value, the second-order moment, and absolute value of the first-order autoregressive moment. Note the ADJSMMV option in the FIT statement to request the SMM covariance adjustment for the parameter estimates. Although these moments have closed form solution as shown by Andersen and Sorensen (1996), the simulation approach significantly simplifies the moment conditions.

Example 18.18: Duration Data Model with Unobserved Heterogeneity

All of the previous three models actually have closed-form moment conditions, so the simulation approach is not necessarily required for the estimation. This example illustrates how to use SMM to estimate a model for which there is no closed-form solution for the moments and thus the traditional GMM method does not apply. The model is the duration data model with unobserved heterogeneity in [Gourieroux and Monfort \(1993\)](#):

$$\begin{aligned}
 y_i &= -\exp(-bx_i - \sigma u_i) \log(v_i) \\
 u_i &\sim N(0, 1) \quad v_i \sim U_{[0,1]}
 \end{aligned}$$

The SAS statements are:

Example 18.19: EMM Estimation of a Stochastic Volatility Model

The efficient method of moments (EMM), introduced by Bansal et al. (1993 and 1995) and Gallant and Tauchen (2001), can be considered a variant of SMM. The idea is to match the efficiency of the maximum likelihood (ML) estimation with the flexibility of the SMM procedure. ML itself can be interpreted as a method of moments procedure, where the *score vector*, the vector of derivatives of the log-likelihood function with respect to the parameters, provides the exactly identifying moment conditions. EMM employs an auxiliary (or pseudo) model that closely matches the true model. The score vector of the auxiliary model provides the moment conditions in the SMM step.

This example uses the SMM feature of PROC MODEL to estimate the simple stochastic volatility (SV) model of Example 18.17 with the EMM method.

Suppose that your data are the time series $\{y_1, y_2, \dots, y_n\}$, and the model that you want to estimate, or the structural model, is characterized by the vector of parameters θ . For the SV model, θ is given by (a, b, s) .

The first step of the EMM method is to fit the data with an auxiliary model (or score generator) that has transition density $f(y_t|Y_{t-1}, \eta)$, parametrized by the pseudo parameter η , where $Y_{t-1} = \{y_{t-1}, \dots, y_1\}$. The auxiliary model must approximate the true data-generating process as closely as possible and be such that ML estimation is feasible.

The only identification requirement is that the dimension of the pseudo parameter η be greater than or equal to that of the structural parameter θ .

Andersen, Chung, and Sorensen (1999) showed that the GARCH(1,1) is an appropriate auxiliary model that leads to a good performance of the EMM estimator for the SV model.

The analytical expression for the GARCH(1,1) model with mean zero is

$$\begin{aligned} y_t &= \sigma_t z_t \\ \sigma_t^2 &= \omega + \alpha y_{t-1} + \beta \sigma_{t-1}^2 \end{aligned}$$

The pseudo parameter vector η is given by (ω, α, β) .

One advantage of such a class of models is that the conditional density of y_t is Gaussian—that is,

$$f(y_t | Y_{t-1}, \eta) \propto \frac{1}{\sigma_t} \exp\left(-\frac{y_t^2}{2\sigma_t^2}\right)$$

Therefore the score vector can easily be computed analytically.

The AUTOREG procedure provides the ML estimates, $\hat{\eta}_n$. The output is stored in the garchout data set, while the estimates are stored in the garchest data set.

```

title1 'Efficient Method of Moments for Stochastic Volatility Model';

/* estimate GARCH(1,1) model */
proc autoreg data=svdata(keep=y)
    outest=garchest
    noprint covout;
    model y = / noint garch=(q=1,p=1);
    output out=garchout cev=gsigmasq r=resid;
run;

```

If the pseudo model is close enough to the structural model, in a suitable sense, Gallant and Long (1997) showed that a consistent estimator of the asymptotic covariance matrix of the sample pseudo-score vector can be obtained from the formula

$$\hat{V}_n = \frac{1}{n} \sum_{t=1}^n s_f(Y_t, \hat{\eta}_n) s_f(Y_t, \hat{\eta}_n)'$$

where $s_f(Y_t, \hat{\eta}_n) = (\partial/\partial\eta_n) \log f(y_t | Y_{t-1}, \hat{\eta}_n)$ denotes the score function of the auxiliary model computed at the ML estimates.

The ML estimates of the GARCH(1,1) model are used in the following SAS statements to compute the variance-covariance matrix \hat{V}_n .

```

/* compute the V matrix */
data vvalues;
    set garchout(keep=y gsigmasq resid);

    /* compute scores of GARCH model */
    score_1 = (-1 + y**2/gsigmasq) / gsigmasq;
    score_2 = (-1 + y**2/gsigmasq)*lag(gsigmasq) / gsigmasq;
    score_3 = (-1 + y**2/gsigmasq)*lag(y**2) / gsigmasq;

    array score{*} score_1-score_3;
    array v_t{*} v_t_1-v_t_6;
    array v{*} v_1-v_6;

```

```

/* compute external product of score vector */
do i=1 to 3;
  do j=i to 3;
    v_t{j*(j-1)/2 + i} = score{i}*score{j};
  end;
end;

/* average them over t */
do s=1 to 6;
  v{s}+ v_t{s}/&nobs;
end;
run;

```

The \hat{V} matrix must be formatted to be used with the VDATA= option of the MODEL procedure. See the section “VDATA= Input data set” on page 1158 for more information about the VDATA= data set.

```

/* Create a VDATA dataset acceptable to PROC MODEL */

/* Transpose the last obs in the dataset */
proc transpose data=vvalues(firstobs=&nobs keep=v_1-v_6)
  out=tempv;
run;

/* Add eq and inst labels */
data vhat;
  set tempv(drop=_name_);
  value = coll;
  drop coll;
  input _type_ $ eq_row $ eq_col $ inst_row $ inst_col $; *$;
  datalines;
    gmm m1 m1 1 1 /* intcpt is the only inst we use */
    gmm m1 m2 1 1
    gmm m2 m2 1 1
    gmm m1 m3 1 1
    gmm m2 m3 1 1
    gmm m3 m3 1 1
  ;

```

The last step of the EMM procedure is to estimate θ by using SMM, where the moment conditions are given by the scores of the auxiliary model.

Given a fixed value of the parameter vector θ and an arbitrarily large T , one can simulate a series $\{\hat{y}_1(\theta), \hat{y}_2(\theta), \dots, \hat{y}_T(\theta)\}$ from the structural model. The EMM estimator is the value $\hat{\theta}_n$ that minimizes the quantity

$$m_T(\theta, \hat{\eta}_n)' \hat{V}_n^{-1} m_T(\theta, \hat{\eta}_n)$$

where

$$m_T(\theta, \hat{\eta}_n) = \frac{1}{T} \sum_{k=1}^T s_f(\hat{Y}_k(\theta), \hat{\eta}_n)$$

is the sample moment condition evaluated at the fixed estimated pseudo parameter $\hat{\eta}_n$. Note that the target function depends on the parameter θ only through the simulated series \hat{y}_k .

The following statements generate a data set that contains $T = 20,000$ replicates of the estimated pseudo parameter $\hat{\eta}_n$ and that is then input to the MODEL procedure. The EMM estimates are found by using the SMM option of the FIT statement. The \hat{V}_n matrix computed above serves as weighting matrix by using the VDATA= option, and the scores of the GARCH(1,1) auxiliary model evaluated at the ML estimates are the moment conditions in the GMM step.

Since the number of structural parameters to estimate (3) is equal to the number of moment equations (3) times the number of instruments (1), the model is exactly identified and the objective function has value zero at the minimum.

For simplicity, the starting values are set to the true values of the parameters.

```

/* USE SMM TO FIND EMM ESTIMATES */

/* Generate dataset of length T */
data emm;
  set garchest(obs=1 keep = _ah_0 _ah_1 _gh_1 _mse_);
  do i=1 to 20000;
    output;
  end;
  drop i;
run;

Overview: PANEL Procedure

The PANEL procedure analyzes a class of linear econometric models that commonly arise when time series and cross-sectional data are combined. This type of pooled data on time series cross-sectional bases is often referred to as panel data. Typical examples of panel data include observations in time on households, countries, firms, trade, and so on. For example, in the case of survey data on household income, the panel is created by repeatedly surveying the same households in different time periods (years).

The panel data models can be grouped into several categories depending on the structure of the error term. The error structures and the corresponding methods that the PANEL procedure uses to analyze data are as follows:

- one-way and two-way models
- fixed-effects and random-effects models
- autoregressive models
- moving-average models

If the specification is dependent only on the cross section to which the observation belongs, such a model is referred to as a one-way model. A specification that depends on both the cross section and the time period to which the observation belongs is called a two-way model.

Apart from the possible one-way or two-way nature of the effect, the other dimension of difference between the possible specifications is the nature of the cross-sectional or time-series effect. The models are referred to as fixed-effects models if the effects are nonrandom and as random-effects models otherwise.

If the effects are fixed, the models are essentially regression models with dummy variables that correspond to the specified effects. For fixed-effects models, ordinary least squares (OLS) estimation is the best linear unbiased estimator. Random-effects models use a two-stage approach. In the first stage, variance components are calculated by using methods described by Fuller and Battese, Wansbeek and Kapteyn, Wallace and Hussain, or Nerlove. In the second stage, variance components are used to standardize the data, and ordinary least squares(OLS) regression is performed.

There are two types of models in the PANEL procedure that accommodate an autoregressive structure. The Parks method is used to estimate a first-order autoregressive model with contemporaneous correlation. The dynamic panel estimator is used to estimate an autoregressive model with lagged dependent variable.

The Da Silva method is used to estimate mixed variance-component moving-average error process. The regression parameters are estimated by using a two-step generalized least squares(GLS)-type estimator.

The new PANEL procedure enhances the features that were implemented in the TSCSREG procedure. The following list shows the most important additions.

- New estimation methods include between estimators, pooled estimators, and dynamic panel estimators that use the generalized method of moments (GMM). The variance components for random-effects models can be calculated for both balanced and unbalanced panels by using the methods described by Fuller and Battese, Wansbeek and Kapteyn, Wallace and Hussain, or Nerlove.
- The CLASS statement creates classification variables that are used in the analysis.
- The TEST statement includes new options for Wald, Lagrange multiplier, and the likelihood ratio tests.
- The new RESTRICT statement specifies linear restrictions on the parameters.
- The FLATDATA statement enables the data to be in a compressed form.
- Several methods that produce heteroscedasticity-consistent covariance matrices (HCCME) are added because the presence of heteroscedasticity can result in inefficient and biased estimates of the variance covariance matrix in the OLS framework.
- The LAG statement can generate a large number of missing values, depending on lag order. Typically, it is difficult to create lagged variables in the panel setting. If lagged variables are created in a DATA step, several programming steps that include loops are often needed. By including the LAG statement, the PANEL procedure makes the creation of lagged values easy.

The missing values can be replaced with zeros, overall mean, time mean, or cross section mean by using the LAG, ZLAG, XLAG, SLAG, and CLAG statements.

- ODS Graphics plots can now be produced by the PANEL procedure. The new plots include residual, predicted, and actual value plots, Q-Q plots, histograms, and profile plots.
- The OUTPUT statement enables you to output data and estimates that can be used in other analyses.

Getting Started: PANEL Procedure

This section demonstrates the use of the PANEL procedure.

Specifying the Input Data

The PANEL procedure is similar to other regression procedures in SAS. Suppose you want to regress the variable *Y* on regressors *X1* and *X2*. Cross sections are identified by the variable *STATE*, and time periods are identified by the variable *DATE*. The input data set used by PROC PANEL must be sorted by cross section and by time within each cross section. Therefore, the first step in PROC PANEL is to make sure that the input data set is sorted. The following statements sort the data set *A* appropriately:

```
proc sort data=a;
  by state date;
run;
```

The next step is to invoke the PANEL procedure and specify the cross section and time series variables in an ID statement. The following statements shows the correct syntax:

```
proc panel data=a;
  id state date;
  model y = x1 x2;
run;
```

Alternatively, PROC PANEL has the capability to read “flat” data. Say that you are using the data set *A*, which has observations on states. Specifically, the data are composed of observations on *Y*, *X1*, and *X2*. Unlike the previous case, the data is not recorded with a PROC PANEL structure. Instead, you have all of a state’s information on a single row. You have variables to denote the name of the state (say *state*). The time observations for the *Y* variable are recorded horizontally. So the variable *Y_1* is the first period’s time observation, *Y_10* is the tenth period’s observation for some state. The same holds for the other variables. You have variables *X1_1* to *X1_10*, *X2_1* to *X2_10*, and *X3_1* to *X3_10* for others. With such data, PROC PANEL could be called by using the following syntax:

```

proc panel data=a;
  flatdata indid = state base = (Y X1 X2) tsname = t;
  id state t;
  model Y = X1 X2;
run;

```

See “[FLATDATA Statement](#)” on page 1320 and [Example 19.2](#) for more information about the use of the FLATDATA statement.

Specifying the Regression Model

The MODEL statement in PROC PANEL is specified like the MODEL statement in other SAS regression procedures: the dependent variable is listed first, followed by an equal sign, followed by the list of regressor variables, as shown in the following statements:

```

proc panel data=a;
  id state date;
  model y = x1 x2;
run;

```

The major advantage of using PROC PANEL is that you can incorporate a model for the structure of the random errors. It is important to consider what kind of error structure model is appropriate for your data and to specify the corresponding option in the MODEL statement.

The error structure options supported by the PANEL procedure are FIXONE, FIXONETIME, FIXTWO, RANONE, RANTWO, PARKS, DASILVA, GMM and ITGMM(iterated GMM). See the section “[Details: PANEL Procedure](#)” on page 1330 for more information about these methods and the error structures they assume. The following statements fit a Fuller-Battese one-way random-effects model.

```

proc panel data=a;
  id state date;
  model y = x1 x2 / ranone vcomp=fb;
run;

```

You can specify more than one error structure option in the MODEL statement; the analysis is repeated using each specified method. You can use any number of MODEL statements to estimate different regression models or estimate the same model by using different options. See [Example 19.1](#) for more information.

In order to aid in model specification within this class of models, the procedure provides two specification test statistics. The first is an F statistic that tests the null hypothesis that the fixed-effects parameters are all zero. The second is a Hausman m statistic that provides information about the appropriateness of the random-effects specification. The m statistic is based on the idea that, under the null hypothesis of no correlation between the effects variables and the regressors, OLS and GLS

are consistent, but OLS is inefficient. Hence, a test can be based on the result that the covariance of an efficient estimator with its difference from an inefficient estimator is zero. Rejection of the null hypothesis might suggest that the fixed-effects model is more appropriate.

The procedure also provides the Buse R-square measure. This number is interpreted as a measure of the proportion of the transformed sum of squares of the dependent variable that is attributable to the influence of the independent variables. In the case of OLS estimation, the Buse R-square measure is equivalent to the usual R-square measure.

Unbalanced Data

In the case of fixed-effects models, random-effects models, between estimators, and dynamic panel estimators, the PANEL procedure can process data with different numbers of time series observations across different cross sections. The Parks and Da Silva methods cannot be used with unbalanced data. The missing time series observations are recognized by the absence of time series ID variable values in some of the cross sections in the input data set. Moreover, if an observation with a particular time series ID value and cross-sectional ID value is present in the input data set, but one or more of the model variables are missing, that time series point is treated as missing for that cross section.

Introductory Example

The following statements use the cost function data from Greene (1990) to estimate the variance components model. The variable PRODUCTION is the log of output in millions of kilowatt-hours, and COST is the log of cost in millions of dollars. Refer to Greene (1990) for details.

```
data greene;
  input firm year production cost @@;
datalines;
  1 1955 5.36598 1.14867 1 1960 6.03787 1.45185
  1 1965 6.37673 1.52257 1 1970 6.93245 1.76627
  2 1955 6.54535 1.35041 2 1960 6.69827 1.71109
  2 1965 7.40245 2.09519 2 1970 7.82644 2.39480
... more lines ...
```

You decide to fit the following model to the data:

$$C_{it} = \text{Intercept} + \beta P_{it} + v_i + e_t + \epsilon_{it} \quad i = 1, \dots, N; \quad t = 1, \dots, T$$

where C_{it} and P_{it} represent the cost and production, and v_i , e_t and ϵ_{it} are the cross-sectional, time series, and error variance components.

If you assume that the time and cross-sectional effects are random, you are left with four possible estimators for the variance components. You choose Fuller-Battese.

The following statements fit this model.

```

proc sort data=greene;
  by firm year;
run;

proc panel data=greene;
  model cost = production / rantwo vcomp = fb;
  id firm year;
run;

```

The PANEL procedure output is shown in Figure 19.1. A model description is printed first, which reports the estimation method used and the number of cross sections and time periods. The variance components estimates are printed next. Finally, the table of regression parameter estimates shows the estimates, standard errors, and *t* tests.

Figure 19.1 The Variance Components Estimates

The PANEL Procedure					
Fuller and Battese Variance Components (RanTwo)					
Dependent Variable: cost					
Model Description					
Estimation Method			RanTwo		
Number of Cross Sections			6

Functional Summary

The statements and options used with the PANEL procedure are summarized in the following table.

Description	Statement	Option
Data Set Options		
Includes correlations in the OUTEST= data set	PANEL	CORROUT
Includes covariances in the OUTEST= data set	PANEL	COVOUT
Specifies the input data set	PANEL	DATA=
Specifies variables to keep but not transform	FLATDATA	KEEP=
Specifies the output data set for CLASS STATEMENT	CLASS	OUT =
Specifies the output data set	FLATDATA	OUT =
Specifies the name of an output SAS data set	OUTPUT	OUT=
Writes parameter estimates to an output data set	PANEL	OUTEST=
Writes the transformed series to an output data set	PANEL	OUTTRANS=
Requests that the procedure produce graphics via the Output Delivery System	PANEL	PLOTS=
Declaring the Role of Variables		
Specifies BY-group processing	BY	
Specifies the classification variables	CLASS	
Transfers the data into uncompressed form	FLATDATA	
Specifies the cross section and time ID variables	ID	

Description	Statement	Option
Declares instrumental variables	INSTRUMENTS	
Lag Generation		
Specifies output data set for lags	CLAG	OUT=
Specifies output data set for lags	LAG	OUT=
Specifies output data set for lags	SLAG	OUT=
Specifies output data set for lags	XLAG	OUT=
Specifies output data set for lags	ZLAG	OUT=
Printing Control Options		
Prints correlations of the estimates	MODEL	CORRB
Prints covariances of the estimates	MODEL	COVB
Suppresses printed output	MODEL	NOPRINT
Requests that the procedure produce graphics via the Output Delivery System	MODEL	PLOTS=
Performs tests of linear hypotheses	TEST	
Model Estimation Options		
Requests the Breusch-Pagan test for one-way random effects	MODEL	BP
Requests the Breusch-Pagan test for two-way random effects	MODEL	BP2
Specifies the between-groups model	MODEL	BTWNG
Specifies the between-time-periods model	MODEL	BTWNT
Specifies the Da Silva method	MODEL	DASILVA
Specifies the one-way fixed-effects model	MODEL	FIXONE
Specifies the one-way fixed-effects model with respect to time	MODEL	FIXONETIME
Specifies the two-way fixed-effects model	MODEL	FIXTWO
Specifies the Moore-Penrose generalized inverse	MODEL	GINV = G4
Specifies the dynamic panel estimator model	MODEL	GMM
Requests the HCCME estimator for the variance-covariance matrix	MODEL	HCCME=
Specifies the order of the moving average error process for Da Silva method	MODEL	M=
Suppresses the intercept term	MODEL	NOINT
Specifies the Parks method	MODEL	PARKS
Prints the Φ matrix for Parks method	MODEL	PHI
Specifies the pooled model	MODEL	POOLED
Specifies the one-way random-effects model	MODEL	RANONE
Specifies the two-way random-effects model	MODEL	RANTWO
Prints autocorrelation coefficients for Parks method	MODEL	RHO
Controls the check for singularity	MODEL	SINGULAR=
Specifies the method for the variance components estimator	MODEL	VCOMP=

Description	Statement	Option
Specifies linear equality restrictions on the parameters	RESTRICT	
Specifies the TEST statement	TEST	WALD, LM, LR

PROC PANEL Statement

PROC PANEL *options* ;

The following options can be specified on the PROC PANEL statement.

DATA=*SAS-data-set*

names the input data set. The input data set must be sorted by cross section and by time period within cross section. If you omit the DATA= option, the most recently created SAS data set is used.

OUTEST=*SAS-data-set*

names an output data set to contain the parameter estimates. When the OUTEST= option is not specified, the OUTEST= data set is not created. See the section “[The OUTEST= Data Set](#)” on page 1368 for details about the structure of the OUTEST= data set.

OUTTRANS=*SAS-data-set*

names an output data set to contain the transformed series for further analysis and computation of models with time observations greater than two. See the section “[The OUTTRANS= Data Set](#)” on page 1370 for details about the structure of the OUTTRANS= data set.

OUTCOV

COVOUT

writes the covariance matrix of the parameter estimates to the OUTEST= data set. See the section “[The OUTEST= Data Set](#)” on page 1368 for details.

OUTCORR

CORROUT

writes the correlation matrix of the parameter estimates to the OUTEST= data set. See the section “[The OUTEST= Data Set](#)” on page 1368 for details.

PLOTS < (*global-plot-options* < (**NCROSS=***value*) >) > < = (*specific-plot-options*) >

requests that statistical graphics be produced via the Output Delivery System, provided that the ODS GRAPHICS statement has been specified. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#)” (*SAS/STAT User’s Guide*). The *global-plot-options* apply to all relevant plots generated by the PANEL procedure.

Global Plot Options

The following *global-plot-options* are supported:

ONLY	suppresses the default plots. Only the plots specifically requested are produced.
UNPACKPANEL UNPACK	breaks a graphic that is otherwise paneled into individual component plots.
NCROSS= <i>value</i>	specifies the number of cross sections to be combined into one time series plot.

Specific Plot Options

The following *specific-plot-options* are supported:

ACTSURFACE	produces a surface plot of actual values.
ALL	produces all appropriate plots.
FITPLOT	plots the predicted and actual values.
NONE	suppresses all plots.
PREDSURFACE	produces a surface plot of predicted values.
QQ	produces a QQ plot of residuals.
RESIDSTACK RESSTACK	produces a stacked plot of residuals.
RESIDSURFACE	produces a surface plot of residual values.
RESIDUAL RES	plots the residuals.
RESIDUALHISTOGRAM RESIDHISTOGRAM	plots the histogram of residuals.

For more details, see the section “[ODS Graphics](#)” on page 1367.

In addition, any of the following MODEL statement options can be specified in the PROC PANEL statement: CORRB, COVB, FIXONE, FIXONETIME, FIXTWO, BTWNG, BTWNT, POOLED, RANONE, RANTWO, FULLER, PARKS, DASILVA, NOINT, NOPRINT, M=, PHI, RHO, VCOMP=, and SINGULAR=. When specified in the PROC PANEL statement, these options are equivalent to specifying the options for every MODEL statement. See the section “[MODEL Statement](#)” on page 1324 for a complete description of each of these options.

BY Statement

BY *variables* ;

A BY statement can be used with PROC PANEL to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the input data set must be sorted by the BY variables as well as by cross section and time period within the BY groups.

The following statements show an example:

```
proc sort data=a;
  by byvar1 byvar2 csid tsid;
run;

proc panel data=a;
  by byvar1 byvar2;
  id csid tsid;
  ...
run;
```

CLASS Statement

CLASS *variables* </ out= SAS-data-set> ;

The CLASS statement names the classification variables to be used in the analysis. Classification variables can be either character or numeric.

In PROC PANEL, the CLASS statement enables you to output class variables to a data set that contains a copy of the original data.

FLATDATA Statement

FLATDATA *options* </ out= SAS-data-set> ;

The following options must be specified in the FLATDATA statement:

BASE=(*variable, variable, ..., variable*)

specifies the variables that are to be transformed into a proper PROC PANEL format. All variables to be transformed must be named according to the convention: `basename_timeperiod`. You supply just the `basename`, and the procedure extracts the appropriate variables to transform. If some year's data are missing for a variable, then PROC PANEL detects this and fills in with missing values.

INDID=*variable*

names the variable in the input data set that uniquely identifies each individual. The INDID variable can be a character or numeric variable.

KEEP=*(variable, variable, ..., variable)*

specifies the variables that are to be copied without any transformation. These variables remain constant with respect to time when the data are converted to PROC PANEL format. This is an optional item.

TSNAME=*name*

specifies a name for the generated time identifier. The name must satisfy the requirements for the name of a SAS variable. The name can be quoted, but it must not be the name of a variable in the input data set.

The following options can be specified on the FLATDATA statement after the slash (/):

OUT =*SAS-data-set*

saves the converted flat data set to a PROC PANEL formatted data set.

ID Statement

ID *cross-section-id time-series-id* ;

The ID statement is used to specify variables in the input data set that identify the cross section and time period for each observation.

When an ID statement is used, the PANEL procedure verifies that the input data set is sorted by the cross section ID variable and by the time series ID variable within each cross section. The PANEL procedure also verifies that the time series ID values are the same for all cross sections.

To make sure the input data set is correctly sorted, use PROC SORT to sort the input data set with a BY statement with the variables listed exactly as they are listed in the ID statement, as shown in the following statements:

```
proc sort data=a;
  by csid tsid;
run;
```

```
proc panel data=a;
  id csid tsid;
  ... etc. ...
run;
```

INSTRUMENT Statement

INSTRUMENTS *options* ;

The INSTRUMENTS statement denotes which variables are used in the moment condition equations of the dynamic panel estimator. The following options can be used with the INSTRUMENTS statement.

CONSTANT

includes an intercept (column of ones) as an uncorrelated exogenous instrument.

DEPVAR

specifies that a dependent variable be used at an appropriate lag as an instrument.

CORRELATED=(*variable, variable, ..., variable*)

specifies a list of variables correlated with the error term. These variables are not used in forming moment conditions from level equations.

EXOGENOUS=(*variable, variable, ..., variable*)

specifies a list of variables that are not correlated with the error term.

PREDETERMINED=(*variable, variable, ..., variable*)

specifies a list of variables whose future realizations can be correlated with the error term but whose present and past realizations are not.

If a variable listed in the EXOGENOUS list is not included in the CORRELATED list, then it is considered to be uncorrelated to the error term. For example, in the following statements, the exogenous instruments are Z1, Z2 and X1. Z1 is an instrument that is correlated to the individual fixed effects.

```
proc panel data=a;
  inst exogenous=(Z1 Z2 X1)
    correlated = (Z1) constant depvar;
  model Y = X1 X2 X3 / gmm;
run;
```

For a detailed discussion of the model set up and the use of the INSTRUMENTS statement, see “Dynamic Panel Estimator” on page 1352.

Note that for each MODEL statement, one INSTRUMENT statement is required. In other words, if there are two models to be estimated by using GMM within one PANEL procedure, then there should be two INSTRUMENT statements. For example,

```
proc panel data=test;
  inst depvar pred=(x1 x2) exog=(x3 x4 x5) correlated=(x3 x4 x5);
  model y = y_1 x1 x2 / gmm maxband=6 nolevels ginv=g4 artest=5;
  inst pred=(x2 x4) exog=(x3 x5) correlated=(x3 x4);
  model y = y_1 x2 / gmm maxband=6 nolevels ginv=g4 artest=5;
  id cs ts;
run;
```

LAG, ZLAG, XLAG, SLAG or CLAG Statement

LAG $var_1(lag_1 lag_2 \dots lag_T), \dots, var_N(lag_1 lag_2 \dots lag_T) < /OUT= SAS-data-set > ;$

Generally, creating lags of variables in a panel setting is a tedious process in which you must generate many DATA STEP statements. The PANEL procedure now enables you to generate lags of any series without jumping across any individual's boundary. The lag statement is a data set generation tool. Using the data created by a LAG statement requires a subsequent PROC PANEL call. There can be more than one LAG statement in each call to PROC PANEL.

The LAG statement tends to generate many missing values in the data. This can be problematic, because the number of usable observations diminishes with the lag length. Therefore, PROC PANEL offers alternatives to the LAG statement. The OUT= option must be specified on the LAG statement. The output data set includes all variables in the input set, plus the lags that are denoted with the convention originalvar_lag. The following statements can be used instead of LAG with otherwise identical syntax:

CLAG

replaces missing values with the cross section mean for that variable in that cross section. Note that missing values are replaced only if they are in the generated (lagged) series. Missing variables in the original variables are not changed.

SLAG

replaces missing values with the time mean for that variable in that time period. Note that missing values are replaced only if they are in the generated (lagged) series. Missing variables in the original variables are not changed.

XLAG

replaces missing values with the overall mean for that variable. Note that missing values are replaced only if they are in the generated (lagged) series. Missing variables in the original variables are not changed.

ZLAG

replaces missing values with zero for that variable. Note that missing values are replaced only if they are in the generated (lagged) series. Missing variables in the original variables are not changed.

Assume that data set A has been sorted by cross section and time period within cross section (or FLATDATA has been specified), and the variables are Y, X1, X2 and X3. You desire the lags 1 and 3 of the X1 variable; lag 3, 6, and 9 of X2; and lag 2 of variable X3. The following PROC PANEL statements generate a series with those characteristics.

```
proc panel data=A;
  id i t;
  lag X1(1 3) X2(3 6 9) X3(2) / out=A_lag;
run;
```

If you want a zeroing instead of missing values, then you specify the following:

```

proc panel data=A;
  id i t;
  zlag X1(1 3) X2(3 6 9) X3(2) / out=A_zlag;
run;

```

Similarly, you can specify XLAG to replace with overall means, SLAG to replace with time means, and CLAG to replace with cross section means.

MODEL Statement

MODEL *response = regressors </ options >* ;

The MODEL statement specifies the regression model and the error structure assumed for the regression residuals. The response variable on the left side of the equal sign is regressed on the independent variables listed after the equal sign. Any number of MODEL statements can be used. For each model statement, only one response variable can be specified on the left side of the equal sign.

The error structure is specified by the FULLER, PARKS, DASILVA, FIXONE, FIXONETIME, FIXTWO, RANONE, RANTWO, GMM, and ITGMM options. More than one of these options can be used, in which case the analysis is repeated for each error structure model specified.

Models can be given labels. Model labels are used in the printed output to identify the results for different models. If no label is specified, the response variable name is used as the label for the model. The model label is specified as follows:

label : MODEL ... ;

The following options can be specified in the MODEL statement after a slash (/).

ARTEST=*integer*

specifies the maximum order of the test for the presence of AR effects in the residual in the dynamic panel model. The acceptable range of values for this option is 1 to $t - 3$.

ATOL=*number*

specifies the convergence criterion for iterated GMM when convergence of the method is determined by convergence in the weighting matrix. The convergence criterion must be positive. The default option is the BTOL= option unless the ATOL= option is specified. See the section “[Dynamic Panel Estimator](#)” on page 1352 for details.

BANDOPT=TRAILING | CENTERED | LEADING

specifies which observations are included in the instrument list when the MAXBAND= option is specified. This option should be used only for exogenous instruments. BANDOPT=TRAILING is the default. See the section “[Dynamic Panel Estimator](#)” on page 1352 for details.

BP

requests the Breusch-Pagan one-way test for random effects.

BP2

requests the Breusch-Pagan two-way test for random effects.

BTOL=number

specifies the convergence criterion for iterated GMM when convergence of the method is determined by convergence in the parameter matrix. The convergence criterion must be positive. The default is BTOL=1e-8. See the section “[Dynamic Panel Estimator](#)” on page 1352 for details.

BTWNG

specifies that a between-groups model be estimated.

BTWNT

specifies that a between-time-periods model be estimated.

CORRB**CORR**

prints the matrix of estimated correlations between the parameter estimates.

COVB**VAR**

prints the matrix of estimated covariances between the parameter estimates.

DASILVA

specifies that the model be estimated by using the Da Silva method, which assumes a mixed variance-component moving-average model for the error structure. See the section “[Da Silva Method \(Variance-Component Moving Average Model\)](#)” on page 1350 for details.

FIXONE

specifies that a one-way fixed-effects model be estimated with the one-way model corresponding to cross-sectional effects only.

FIXONETIME

specifies that a one-way fixed-effects model be estimated with the one-way model corresponding to time effects only.

FIXTWO

specifies that a two-way fixed-effects model be estimated.

GINV= G2 | G4

specifies what type of generalized inverse to use. The default is a G2 inverse. The G4 inverse is generally more desirable except that it is a more numerically intensive methodology.

GMM

specifies that the model be estimated by using the dynamic panel estimator method, which allows for autoregressive processes. This is the single-step model. Note that with this option one INSTRUMENT statement is required for each MODEL statement. See the section “[Dynamic Panel Estimator](#)” on page 1352 for details.

HCCME=number

specifies the type of HCCME variance-covariance matrix requested. The expected range of values is NO or 0 to 4. The default is NO, no correction. See the section “[Heteroscedasticity-Corrected Covariance Matrices](#)” on page 1361 for details.

ITGMM

specifies that the model be estimated by using the dynamic panel estimator method, but that PROC PANEL keep updating the weighting matrix until either the parameter vector converges or the weighting matrix converges. See the section “[Dynamic Panel Estimator](#)” on page 1352 for details.

ITPRINT

prints out the iteration history of the parameter and transformed sum of error squared.

M=number

specifies the order of the moving-average process in the Da Silva method. The value of the M=option must be less than $T - 1$. The default is M=1.

MAXBAND=integer

specifies the maximum number of time periods (per instrumental variable) that are allowed into the moment condition. The acceptable range of values for this option is 1 to $T - 1$. If BANDOPT=LEADING or CENTERED, then the default value of MAXBAND is 2. If BANDOPT=TRAILING, then the default value of MAXBAND is 1. If no BANDOPT option is specified such as when no exogenous instruments are used, then the default value of MAXBAND is 1. See the section “[Dynamic Panel Estimator](#)” on page 1352 for details.

MAXITER=integer

specifies the maximum number of iterations allowed for the iterated GMM option. The default value is MAXITER=200. See the section “[Dynamic Panel Estimator](#)” on page 1352 for details.

NODIFFS

specifies that the dynamic panel model be estimated without moment conditions from the difference equations. See the section “[Dynamic Panel Estimator](#)” on page 1352 for details.

NOESTIM

limits the estimation of a FIXONE, FIXONETIME, RANONE model to the generation of the transformed series. This option is intended for use with an OUTTRANS= data set.

NOINT

suppresses the intercept parameter from the model.

NOLEVELS

specifies that the dynamic panel model be estimated without moment conditions from the level equations. See the section “[Dynamic Panel Estimator](#)” on page 1352 for details.

NOPRINT

suppresses the normal printed output.

PARKS

specifies that the model be estimated by using the Parks method, which assumes a first-order

autoregressive model for the error structure. See the section “[Parks Method \(Autoregressive Model\)](#)” on page 1348 for details.

PHI

prints the Φ matrix of estimated covariances of the observations for the Parks method. The PHI option is relevant only when the PARKS option is used. See the section “[Parks Method \(Autoregressive Model\)](#)” on page 1348 for details.

POOLED

specifies that a pooled (OLS) model be estimated.

RANONE

specifies that a one-way random-effects model be estimated.

RANTWO

specifies that a two-way random-effects model be estimated.

RHO

prints the estimated autocorrelation coefficients for the Parks method.

ROBUST

specifies that the robust weighting matrix be used in the calculation of the variance-covariance matrix of the single-step dynamic panel estimator. See the section “[Dynamic Panel Estimator](#)” on page 1352 for details.

SINGULAR=number

specifies a singularity criterion for the inversion of the matrix. The default depends on the precision of the computer system.

TIME

specifies that the model be estimated by using the dynamic panel estimator method, but that PROC PANEL includes time dummy variables to model any time effects present in the data. See the section “[Dynamic Panel Estimator](#)” on page 1352 for details.

TWOSTEP

specifies that the model be estimated by using the dynamic panel estimator method, but that two steps be used in the estimation. An initial first step is used to form an estimator for the weighting matrix used in the second step. See the section “[Dynamic Panel Estimator](#)” on page 1352 for details.

VCOMP=FB | NL | WH | WK

specifies the type of variance component estimate to use. The default is VCOMP=FB for balanced data and VCOMP=WK for unbalanced data. See the section “[The One-Way Random-Effects Model](#)” on page 1340 and “[The Two-Way Random-Effects Model](#)” on page 1343 for details.

OUTPUT Statement

OUTPUT *OUT=SAS-data-set* < = options ... > ;

The OUTPUT statement creates an output SAS data set as specified by the following options:

OUT=SAS-data-set

names the output SAS data set to contain the predicted and transformed values. If the OUT= option is not specified, the new data set is named according to the DATA*n* convention.

PREDICTED=name

P=name

writes the predicted values to the output data set.

RESIDUAL=name

R=name

writes the residuals from the predicted values based on both the structural and time series parts of the model to the output data set.

RESTRICT Statement

RESTRICT < "string" > *equation* < ,*equation2*... > ;

The RESTRICT statement specifies linear equality restrictions on the parameters in the previous model statement. There can be as many unique restrictions as the number of parameters in the preceding model statement. Multiple RESTRICT statements are understood as joint restrictions on a model's parameters. Restrictions on the intercept are obtained by the use of the keyword INTERCEPT.

Currently, only linear equality restrictions are permitted in PROC PANEL. Tests and restriction expressions can only be composed of algebraic operations that involve the addition symbol (+), subtraction symbol (−), and multiplication symbol (*).

The RESTRICT statement accepts labels that are produced in the printed output. RESTRICT statement can be labeled in two ways. A RESTRICT statement can be preceded by a label followed by a colon. This is illustrated in **rest1** in the example below. Alternatively, the keyword RESTRICT can be followed by a quoted string.

The following statements illustrate the use of the RESTRICT statement:

```
proc panel;
  model y = x1 x2 x3;
  restrict x1 = 0, x2 * .5 + 2 * x3 = 0;
  rest1: restrict x2 = 0, x3 = 0;
  restrict "rest2" intercept=1;
run;
```

Note that a restrict statement cannot include a division sign in its formulation.

TEST Statement

```
TEST <"string"> equation <,equation2...> / options ;
```

The TEST statement performs Wald, Lagrange multiplier and likelihood ratio tests of linear hypotheses about the regression parameters in the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. All hypotheses in one TEST statement are tested jointly. Variable names in the equations must correspond to regressors in the preceding MODEL statement, and each name represents the coefficient of the corresponding regressor. The keyword INTERCEPT refers to the coefficient of the intercept.

The following options can be specified on the TEST statement after the slash (/):

ALL

specifies Wald, Lagrange multiplier and likelihood ratio tests.

WALD

specifies the WALD test.

LM

specifies the Lagrange multiplier test.

LR

specifies the likelihood ratio test.

The Wald test is performed by default.

The following statements illustrate the use of the TEST statement:

```
proc panel;
  id csid tsid;
  model y = x1 x2 x3;
  test x1 = 0, x2 * .5 + 2 * x3 = 0;
  test_int: test intercept = 0, x3 = 0;
run;
```

The first test investigates the joint hypothesis that

$$\beta_1 = 0$$

and

$$.5\beta_2 + 2\beta_3 = 0$$

Currently, only linear equality restrictions and tests are permitted in PROC PANEL. Tests and restriction expressions can be composed only of algebraic operations that involve the addition symbol (+), subtraction symbol (-), and multiplication symbol (*).

The TEST statement accepts labels that are produced in the printed output. The TEST statement can be labeled in two ways. A TEST statement can be preceded by a label followed by a colon. Alternatively, the keyword TEST can be followed by a quoted string. If both are presented, PROC PANEL uses the quoted string. In the event no label is present, PROC PANEL automatically labels the tests. If both a TEST and a RESTRICT statement are specified, the test is run with restrictions applied.

Note that for the DaSilva method, only the WALD test is available.

Details: PANEL Procedure

Missing Values

Any observation in the input data set with a missing value for one or more of the regressors is ignored by PROC PANEL and is not used in the model fit.

If there are observations in the input data set with missing dependent variable values but with nonmissing regressors, PROC PANEL can compute predicted values and store them in an output data set by using the OUTPUT statement. Note that the presence of such observations with missing dependent variable values does not affect the model fit because these observations are excluded from the calculation.

If either some regressors or the dependent variable values are missing, the model is estimated as unbalanced where the number of time series observations across different cross sections does not have to be equal. The Parks and Da Silva methods cannot be used with unbalanced data.

Computational Resources

The more parameters there are to be estimated, the more memory and time are required to estimate the model. Also affecting these resources are the estimation method chosen and the method to calculate variance components. If the model has p parameters including the intercept, there are at least $p + [p * (p + 1)]/2$ numbers being held in the memory.

If the Arellano and Bond GMM approach is used, the amount of memory grows proportionately to the number of instruments in the INSTRUMENT statement. If the ITGMM (iterated GMM) option is selected, the computation time also depends on the convergence criteria selected and the maximum number of iterations allowed.

Restricted Estimates

A consequence of estimating a linear model with a restriction is that the error degrees of freedom increase by the number of restrictions. PROC PANEL produces the Lagrange multiplier associated with each restriction.

Say that you are interested in linear regression in which there are r restrictions. A linear restriction implies the following set of equations that relate the regression coefficients:

$$\begin{aligned} R_{1,1}\beta_1 + R_{1,2}\beta_2 + \dots + R_{1,p}\beta_p &= q_1 \\ R_{2,1}\beta_1 + R_{2,2}\beta_2 + \dots + R_{2,p}\beta_p &= q_2 \\ &\dots\dots\dots \\ R_{r,1}\beta_1 + R_{r,2}\beta_2 + \dots + R_{r,p}\beta_p &= q_r \end{aligned}$$

To economize on notation, you can represent the restriction structure in the following matrix notation $\mathbf{R}\boldsymbol{\beta} = \mathbf{q}$. The restricted $\boldsymbol{\beta}$ estimator is given by:

$$\boldsymbol{\beta}^* = \boldsymbol{\beta} - (\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}' \left[\mathbf{R}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}' \right]^{-1} (\mathbf{R}\boldsymbol{\beta} - \mathbf{q})$$

The Lagrange multipliers are given as:

$$\boldsymbol{\lambda}_* = \left[\mathbf{R}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}' \right]^{-1} (\mathbf{R}\boldsymbol{\beta} - \mathbf{q})$$

The standard errors of the Lagrange Multipliers are calculated from the following relationship:

$$\text{Var}(\boldsymbol{\lambda}_*) = \left[\mathbf{R}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}' \right]^{-1} \mathbf{R}\text{Var}(\boldsymbol{\beta})\mathbf{R}' \left[\mathbf{R}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}' \right]^{-1}$$

A significant Lagrange multiplier implies that you can reject the null hypothesis that the restrictions are not binding.

Note that in the special case of the fixed-effects models, the NOINT option and RESTRICT INTERCEPT=0 option give different estimates. This is not an error; it reflects two perspectives on the same issue. In the FIXONE case, the intercept is the last cross section's fixed effect (or the last time affecting the case of FIXONETIME). Specifying the NOINT option removes the intercept, but allows the last effect in. The NOINT command simply reclassifies the effects. The dummy variables become true cross section effects. If you specify the NOINT option with the FIXTWO option, the restriction is imposed that the last time effect is zero. A RESTRICT INTERCEPT=0 statement suppresses the estimation of the last effect in the FIXONE and FIXONETIME case. A RESTRICT INTERCEPT=0 has similar effects on the FIXTWO estimator. In general, restricting the intercept to zero is not recommended because OLS loses its unbiased nature.

Notation

The following notation represents the usual panel structure, with the specification of u_{it} dependent on the particular model:

$$y_{it} = \sum_{k=1}^K x_{itk}\beta_k + u_{it} \quad i = 1, \dots, N; t = 1, \dots, T_i$$

The total number of observations $M = \sum_{i=1}^N T_i$. For the balanced data case, $T_i = T$ for all i . The $M \times M$ covariance matrix of u_{it} is denoted by \mathbf{V} . Let \mathbf{X} and \mathbf{y} be the independent and dependent variables arranged by cross section and by time within each cross section. Let \mathbf{X}_s be the X matrix without the intercept. All other notation is specific to each section.

The One-Way Fixed-Effects Model

The specification for the one-way fixed-effects model is

$$u_{it} = \gamma_i + \epsilon_{it}$$

where the γ_i s are nonrandom parameters to be estimated.

Let $\mathbf{Q}_0 = \text{diag}(\mathbf{E}_{T_i})$, with $\bar{\mathbf{J}}_{T_i} = \mathbf{J}_{T_i}/T_i$ and $\mathbf{E}_{T_i} = \mathbf{I}_{T_i} - \bar{\mathbf{J}}_{T_i}$, where \mathbf{J}_{T_i} is a matrix of T_i ones.

The matrix \mathbf{Q}_0 represents the within transformation. In the one-way model, the within transformation is the conversion of the raw data to deviations from a cross section's mean. The vector $\tilde{\mathbf{x}}_{it}$ is a row of the general matrix \mathbf{X}_s , where the subscripted s implies the constant (column of ones) is missing.

Let $\tilde{\mathbf{X}}_s = \mathbf{Q}_0 \mathbf{X}_s$ and $\tilde{\mathbf{y}} = \mathbf{Q}_0 \mathbf{y}$. The estimator of the slope coefficients is given by

$$\tilde{\beta}_s = (\tilde{\mathbf{X}}_s' \tilde{\mathbf{X}}_s)^{-1} \tilde{\mathbf{X}}_s' \tilde{\mathbf{y}}$$

Once the slope estimates are in hand, the estimation of an intercept or the cross-sectional fixed effects is handled as follows. First, you obtain the cross-sectional effects:

$$\gamma_i = \bar{y}_i - \tilde{\beta}_s \bar{x}_i \quad \text{for } i = 1 \dots N$$

If the NOINT option is specified, then the dummy variables' coefficients are set equal to the fixed effects. If an intercept is desired, then the i th dummy variable is obtained from the following expression:

$$D_i = \gamma_i - \gamma_N \quad \text{for } i = 1 \dots N - 1$$

The intercept is the N th fixed effect γ_N .

The within model sum of squared errors is:

$$\text{SSE} = \sum_{i=1}^N \sum_{t=1}^{T_i} (y_{it} - \gamma_i - \mathbf{X}_s \tilde{\beta}_s)^2$$

The estimated error variance can be written:

$$\hat{\sigma}_\epsilon^2 = \text{SSE}/(M - N - (K - 1))$$

Alternatively, an equivalent way to express the error variance is

$$\hat{\sigma}_\epsilon^2 = \tilde{\mathbf{u}}' \mathbf{Q}_0 \tilde{\mathbf{u}} / (M - N - (K - 1))$$

where the residuals $\tilde{\mathbf{u}}$ are given by $\tilde{\mathbf{u}} = (\mathbf{I}_M - \mathbf{J}_M \mathbf{J}'_M / M)(\mathbf{y} - \mathbf{X}_s \tilde{\beta}_s)$ if there is an intercept and by $\tilde{\mathbf{u}} = (\mathbf{y} - \mathbf{X}_s \tilde{\beta}_s)$ if there is not. The drawback is that the formula changes (but the results do not) with the inclusion of a constant.

The variance covariance matrix of $\tilde{\beta}_s$ is given by:

$$\text{Var} [\tilde{\beta}_s] = \hat{\sigma}_\epsilon^2 (\tilde{\mathbf{X}}_s' \tilde{\mathbf{X}}_s)^{-1}$$

The covariance of the dummy variables and the dummy variables with the $\tilde{\beta}_s$ is dependent on whether the intercept is included in the model.

- *no intercept:*

$$\text{Var} [\gamma_i] = \text{Var} [D_i] = \frac{\hat{\sigma}_\epsilon^2}{T_i} + \bar{\mathbf{x}}_i' \text{Var} [\tilde{\beta}_s] \bar{\mathbf{x}}_i.$$

$$\text{Cov} [\gamma_i, \gamma_j] = \text{Cov} [D_i D_j] = \bar{\mathbf{x}}_i' \text{Var} [\tilde{\beta}_s] \bar{\mathbf{x}}_j.$$

$$\text{Cov} [\gamma_i, \tilde{\beta}_s] = \text{Cov} [D_i \tilde{\beta}_s] = -\bar{\mathbf{x}}_i' \text{Var} [\tilde{\beta}_s]$$

- *intercept:*

$$\text{Var} [D_i] = \frac{\hat{\sigma}_\epsilon^2}{T_i} + (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})' \text{Var} [\tilde{\beta}_s] (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})$$

$$\text{Cov} [D_i, D_j] = \frac{\hat{\sigma}_\epsilon^2}{T_i} + (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})' \text{Var} [\tilde{\beta}_s] (\bar{\mathbf{x}}_j - \bar{\mathbf{x}}_{N\cdot})$$

$$\text{Var} [\text{Intercept}] = \text{Var} [\gamma_N] = \frac{\hat{\sigma}_\epsilon^2}{T_N} + \bar{\mathbf{x}}_N' \text{Var} [\tilde{\beta}_s] \bar{\mathbf{x}}_N.$$

$$\text{Cov} [D_i, \tilde{\beta}_s] = -(\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})' \text{Var} [\tilde{\beta}_s]$$

$$\text{Cov} [\text{Intercept}, D_i] = -\frac{\hat{\sigma}_\epsilon^2}{T_i} + \bar{\mathbf{x}}_N' \text{Var} [\tilde{\beta}_s] (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})$$

$$\text{Cov} [\text{Intercept}, \tilde{\beta}_s] = -\bar{\mathbf{x}}_N' \text{Var} [\tilde{\beta}_s]$$

Alternatively, the model option `FIXONETIME` estimates a one-way model where the heterogeneity comes from time effects. This option is analogous to re-sorting the data by time and then by cross section and running a `FIXONE` model. The advantage of using the `FIXONETIME` option is that sorting is avoided and the model remains labeled correctly.

The Two-Way Fixed-Effects Model

The specification for the two-way fixed-effects model is

$$u_{it} = \gamma_i + \alpha_t + \epsilon_{it}$$

where the γ_i s and α_t s are nonrandom parameters to be estimated.

If you do not specify the NOINT option, which suppresses the intercept, the estimates for the fixed effects are reported under the restriction that $\gamma_N = 0$ and $\alpha_T = 0$. If you specify the NOINT option to suppress the intercept, only the restriction $\alpha_T = 0$ is imposed.

Balanced Panels

Assume that the data are balanced (for example, all cross sections have T observations). Then you can write the following:

$$\tilde{y}_{it} = y_{it} - \bar{y}_{i\cdot} - \bar{y}_{\cdot t} + \bar{\bar{y}}$$

$$\tilde{\mathbf{x}}_{it} = \mathbf{x}_{it} - \bar{\mathbf{x}}_{i\cdot} - \bar{\mathbf{x}}_{\cdot t} + \bar{\bar{\mathbf{x}}}$$

where the symbols:

y_{it} and \mathbf{x}_{it} are the dependent variable (a scalar) and the explanatory variables (a vector whose columns are the explanatory variables not including a constant), respectively

$\bar{y}_{i\cdot}$ and $\bar{\mathbf{x}}_{i\cdot}$ are cross section means

$\bar{y}_{\cdot t}$ and $\bar{\mathbf{x}}_{\cdot t}$ are time means

$\bar{\bar{y}}$ and $\bar{\bar{\mathbf{x}}}$ are the overall means

The two-way fixed-effects model is simply a regression of \tilde{y}_{it} on $\tilde{\mathbf{x}}_{it}$. Therefore, the two-way β is given by:

$$\tilde{\beta}_s = (\tilde{\mathbf{X}}' \tilde{\mathbf{X}})^{-1} \tilde{\mathbf{X}}' \tilde{\mathbf{y}}$$

The calculations of cross section dummy variables, time dummy variables, and intercepts follow in a fashion similar to that used in the one-way model.

First, you obtain the net cross-sectional and time effects. Denote the cross-sectional effects by γ and the time effects by α . These effects are calculated from the following relations:

$$\hat{\gamma}_i = (\bar{y}_{i\cdot} - \bar{\bar{y}}) - \tilde{\beta}_s (\bar{x}_{i\cdot} - \bar{\bar{x}})$$

$$\hat{\alpha}_t = (\bar{y}_{\cdot t} - \bar{\bar{y}}) - \tilde{\beta}_s (\bar{x}_{\cdot t} - \bar{\bar{x}})$$

Denote the cross-sectional dummy variables and time dummy variables with the superscript C and T. Under the NOINT option the following equations give the dummy variables:

$$D_i^C = \hat{\gamma}_i + \hat{\alpha}_T$$

$$D_i^T = \hat{\alpha}_t - \hat{\alpha}_T$$

When an intercept is specified, the equations for dummy variables and intercept are:

$$D_i^C = \hat{\gamma}_i - \hat{\gamma}_N$$

$$D_i^T = \hat{\alpha}_t - \hat{\alpha}_T$$

$$\text{Intercept} = \hat{\gamma}_N + \hat{\alpha}_T$$

The sum of squared errors is:

$$\text{SSE} = \sum_{i=1}^N \sum_{t=1}^T (y_{it} - \gamma_i - \alpha_t - \mathbf{X}_s \tilde{\beta}_s)^2$$

The estimated error variance is:

$$\hat{\sigma}_\epsilon^2 = \text{SSE} / (M - N - T - (K - 1))$$

With or without a constant, the variance covariance matrix of $\tilde{\beta}_s$ is given by:

$$\text{Var}[\tilde{\beta}_s] = \hat{\sigma}_\epsilon^2 (\tilde{\mathbf{X}}_s' \tilde{\mathbf{X}}_s)^{-1}$$

Variance Covariance of Dummy Variables with No Intercept

The variances and covariances of the dummy variables are given with the NOINT specification as follows:

$$\begin{aligned} \text{Var}(D_i^C) &= \hat{\sigma}_\epsilon^2 \left(\frac{1}{T} + \frac{1}{N} - \frac{1}{NT} \right) \\ &\quad + (\bar{\mathbf{x}}_i + \bar{\mathbf{x}}_t - \bar{\bar{\mathbf{x}}})' \text{Var}[\tilde{\beta}_s] (\bar{\mathbf{x}}_i + \bar{\mathbf{x}}_t - \bar{\bar{\mathbf{x}}}) \end{aligned}$$

$$\text{Var}(D_i^T) = \frac{2\hat{\sigma}_\epsilon^2}{N} + (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_T)' \text{Var}[\tilde{\beta}_s] (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_T)$$

$$\begin{aligned} \text{Cov}(D_i^C, D_j^C) &= \hat{\sigma}_\epsilon^2 \left(\frac{1}{N} - \frac{1}{NT} \right) \\ &\quad + (\bar{\mathbf{x}}_i + \bar{\mathbf{x}}_t - \bar{\bar{\mathbf{x}}})' \text{Var}[\tilde{\beta}_s] (\bar{\mathbf{x}}_j + \bar{\mathbf{x}}_t - \bar{\bar{\mathbf{x}}}) \end{aligned}$$

$$\text{Cov}(D_i^T, D_u^T) = \frac{\hat{\sigma}_\epsilon^2}{N} + (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_T)' \text{Var}[\tilde{\beta}_s] (\bar{\mathbf{x}}_u - \bar{\mathbf{x}}_T)$$

$$\text{Cov}(D_i^C, D_i^T) = -\frac{\hat{\sigma}_\epsilon^2}{N} + (\bar{\mathbf{x}}_i + \bar{\mathbf{x}}_t - \bar{\bar{\mathbf{x}}})' \text{Var}[\tilde{\beta}_s] (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_T)$$

$$\text{Cov}(D_i^C, \beta) = -(\bar{\mathbf{x}}_i + \bar{\mathbf{x}}_t - \bar{\bar{\mathbf{x}}})' \text{Var}[\tilde{\beta}_s]$$

$$\text{Cov}(D_i^T, \beta) = -(\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_T)' \text{Var}[\tilde{\beta}_s]$$

Variance Covariance of Dummy Variables with Intercept

The variances and covariances of the dummy variables are given when the intercept is included as follows:

$$\begin{aligned} \text{Var} \left(D_i^C \right) &= \frac{\hat{\sigma}_\epsilon^2}{T} + (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})' \text{Var} \left[\tilde{\beta}_s \right] (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot}) \\ \text{Var} \left(D_t^T \right) &= \frac{2\hat{\sigma}_\epsilon^2}{N} + (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_{\cdot T})' \text{Var} \left[\tilde{\beta}_s \right] (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_{\cdot T}) \\ \text{Var} (\text{Intercept}) &= \hat{\sigma}_\epsilon^2 \left(\frac{1}{T} + \frac{1}{N} - \frac{1}{NT} \right) + (\bar{\mathbf{x}}_{N\cdot} + \bar{\mathbf{x}}_{\cdot T} - \bar{\mathbf{x}})' \text{Var} \left[\tilde{\beta}_s \right] (\bar{\mathbf{x}}_{N\cdot} + \bar{\mathbf{x}}_{\cdot T} - \bar{\mathbf{x}}) \\ \text{Cov} \left(D_i^C, D_j^C \right) &= \frac{\hat{\sigma}_\epsilon^2}{T} + (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})' \text{Var} \left[\tilde{\beta}_s \right] (\bar{\mathbf{x}}_j - \bar{\mathbf{x}}_{N\cdot}) \\ \text{Cov} \left(D_t^T, D_u^T \right) &= (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_{\cdot T})' \text{Var} \left[\tilde{\beta}_s \right] (\bar{\mathbf{x}}_u - \bar{\mathbf{x}}_{\cdot T}) \\ \text{Cov} \left(D_i^C, \text{Intercept} \right) &= - \left(\frac{\hat{\sigma}_\epsilon^2}{T} \right) + (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})' \text{Var} \left(\tilde{\beta}_s \right) (\bar{\mathbf{x}}_{N\cdot} + \bar{\mathbf{x}}_{\cdot T} - \bar{\mathbf{x}}) \\ \text{Cov} \left(D_t^T, \text{Intercept} \right) &= - \left(\frac{\hat{\sigma}_\epsilon^2}{N} \right) + (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_{\cdot T})' \text{Var} \left[\tilde{\beta}_s \right] (\bar{\mathbf{x}}_{N\cdot} + \bar{\mathbf{x}}_{\cdot T} - \bar{\mathbf{x}}) \\ \text{Cov} \left(D_i^C, \tilde{\beta} \right) &= - (\bar{\mathbf{x}}_i - \bar{\mathbf{x}}_{N\cdot})' \text{Var} \left[\tilde{\beta}_s \right] \\ \text{Cov} \left(D_t^T, \tilde{\beta} \right) &= - (\bar{\mathbf{x}}_t - \bar{\mathbf{x}}_{\cdot T})' \text{Var} \left[\tilde{\beta}_s \right] \\ \text{Cov} \left(\text{Intercept}, \tilde{\beta} \right) &= - (\bar{\mathbf{x}}_{N\cdot} + \bar{\mathbf{x}}_{\cdot T} - \bar{\mathbf{x}})' \text{Var} \left[\tilde{\beta}_s \right] \end{aligned}$$

Unbalanced Panels

Let \mathbf{X}_* and \mathbf{y}_* be the independent and dependent variables arranged by time and by cross section within each time period. (Note that the input data set used by the PANEL procedure must be sorted by cross section and then by time within each cross section.) Let M_t be the number of cross sections observed in year t and let $\sum_t M_t = M$. Let \mathbf{D}_t be the $M_t \times N$ matrix obtained from the $N \times N$ identity matrix from which rows that correspond to cross sections not observed at time t have been omitted. Consider

$$\mathbf{Z} = (\mathbf{Z}_1, \mathbf{Z}_2)$$

where $\mathbf{Z}_1 = (\mathbf{D}'_1, \mathbf{D}'_2, \dots, \mathbf{D}'_T)'$ and $\mathbf{Z}_2 = \text{diag}(\mathbf{D}_1 \mathbf{j}_N, \mathbf{D}_2 \mathbf{j}_N, \dots, \mathbf{D}_T \mathbf{j}_N)$. The matrix \mathbf{Z} gives the dummy variable structure for the two-way model.

Let

$$\begin{aligned}\Delta_N &= \mathbf{Z}'_1 \mathbf{Z}_1 \\ \Delta_T &= \mathbf{Z}'_2 \mathbf{Z}_2 \\ \mathbf{A} &= \mathbf{Z}'_2 \mathbf{Z}_1 \\ \bar{\mathbf{Z}} &= \mathbf{Z}_2 - \mathbf{Z}_1 \Delta_N^{-1} \mathbf{A}' \\ \mathbf{Q} &= \Delta_T - \mathbf{A} \Delta_N^{-1} \mathbf{A}' \\ \mathbf{P} &= (\mathbf{I}_M - \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}'_1) - \bar{\mathbf{Z}} \mathbf{Q}^{-1} \bar{\mathbf{Z}}'\end{aligned}$$

The estimate of the regression slope coefficients is given by

$$\tilde{\beta}_s = (\mathbf{X}'_{*s} \mathbf{P} \mathbf{X}_{*s})^{-1} \mathbf{X}'_{*s} \mathbf{P} \mathbf{y}_*$$

where \mathbf{X}_{*s} is the \mathbf{X}_* matrix without the vector of 1s.

The estimator of the error variance is

$$\hat{\sigma}_\epsilon^2 = \tilde{\mathbf{u}}' \mathbf{P} \tilde{\mathbf{u}} / (M - T - N + 1 - (K - 1))$$

where the residuals are given by $\tilde{\mathbf{u}} = (\mathbf{I}_M - \mathbf{j}_M \mathbf{j}'_M / M)(\mathbf{y}_* - \mathbf{X}_{*s} \tilde{\beta}_s)$ if there is an intercept in the model and by $\tilde{\mathbf{u}} = \mathbf{y}_* - \mathbf{X}_{*s} \tilde{\beta}_s$ if there is no intercept.

The actual implementation is quite different from the theory. The PANEL procedure transforms all series using the \mathbf{P} matrix.

$$\tilde{\mathbf{v}} = \mathbf{P} \mathbf{v}$$

The variable being transformed is v , which could be \mathbf{y} or any column of \mathbf{X} . After the data are properly transformed, OLS is run on the resulting series.

Given $\tilde{\beta}_s$, the next step is estimating the cross-sectional and time effects. Given that $\boldsymbol{\gamma}$ is the column vector of cross-sectional effects and $\boldsymbol{\alpha}$ is the column vector of time effects,

$$\begin{aligned}\tilde{\boldsymbol{\alpha}} &= \mathbf{Q}^{-1} \bar{\mathbf{Z}}' \mathbf{y} - \mathbf{Q}^{-1} \bar{\mathbf{Z}}' \mathbf{X}_s \tilde{\beta}_s \\ \tilde{\boldsymbol{\gamma}} &= (\Theta_1 + \Theta_2 - \Theta_3) \mathbf{y} - (\Theta_1 + \Theta_2 - \Theta_3) \mathbf{X}_s \tilde{\beta}_s \\ \Theta_1 &= \Delta_N^{-1} \mathbf{Z}'_1 \\ \Theta_2 &= \Delta_N^{-1} \mathbf{A}' \mathbf{Q}^{-1} \mathbf{Z}'_2 \\ \Theta_3 &= \Delta_N^{-1} \mathbf{A}' \mathbf{Q}^{-1} \mathbf{A} \Delta_N^{-1} \mathbf{Z}'_1\end{aligned}$$

Given the cross-sectional and time effects, the next step is to derive the associated dummy variables. Using the NOINT option, the following equations give the dummy variables:

$$\begin{aligned}D_i^C &= \hat{\gamma}_i + \hat{\alpha}_T \\ D_t^T &= \hat{\alpha}_t - \hat{\alpha}_T\end{aligned}$$

When an intercept is desired, the equations for dummy variables and intercept are:

$$D_i^C = \hat{\gamma}_i - \hat{\gamma}_N$$

$$D_t^T = \hat{\alpha}_t - \hat{\alpha}_T$$

$$\text{Intercept} = \hat{\gamma}_N + \hat{\alpha}_T$$

The calculation of the variance-covariance matrix is as follows:

$$\begin{aligned} \text{Var}[\hat{\boldsymbol{\gamma}}] &= \hat{\sigma}_\epsilon^2 (\Delta_N^{-1} - \Sigma_1 + \Sigma_2) \\ &+ (\Theta_1 + \Theta_2 - \Theta_3) \text{Var}[\tilde{\boldsymbol{\beta}}_s] (\Theta_1 + \Theta_2 - \Theta_3)' \end{aligned}$$

where

$$\Sigma_1 = \Delta_N^{-1} \mathbf{A}' \mathbf{Q}^{-1} \mathbf{A} \Delta_N^{-1} \mathbf{A}' \mathbf{Q}^{-1} \mathbf{A} \Delta_N^{-1}$$

$$\Sigma_2 = \Delta_N^{-1} \mathbf{A}' \mathbf{Q}^{-1} \Delta_T \mathbf{Q}^{-1} \mathbf{A} \Delta_N^{-1}$$

$$\text{Var}[\hat{\boldsymbol{\alpha}}] = \hat{\sigma}_\epsilon^2 (\mathbf{Q}^{-1} \bar{\mathbf{Z}}' \bar{\mathbf{Z}} \mathbf{Q}^{-1}) + (\mathbf{Q}^{-1} \bar{\mathbf{Z}}' \mathbf{X}_s) \text{Var}[\tilde{\boldsymbol{\beta}}_s] (\mathbf{X}_s' \bar{\mathbf{Z}} \mathbf{Q}^{-1})$$

$$\begin{aligned} \text{Cov}[\hat{\boldsymbol{\alpha}}, \hat{\boldsymbol{\gamma}}'] &= \hat{\sigma}_\epsilon^2 \Delta_N^{-1} [\mathbf{A}' \mathbf{Q}^{-1} \Delta_T - \mathbf{A}' \mathbf{Q}^{-1} \mathbf{A} \Delta_N^{-1} \mathbf{A}'] \mathbf{Q}^{-1} \\ &+ (\Theta_1 + \Theta_2 - \Theta_3) \text{Var}[\tilde{\boldsymbol{\beta}}_s] (\mathbf{X}_s' \bar{\mathbf{Z}} \mathbf{Q}^{-1}) \end{aligned}$$

$$\text{Cov}[\hat{\boldsymbol{\gamma}}, \tilde{\boldsymbol{\beta}}] = (\Theta_1 + \Theta_2 - \Theta_3) \text{Var}[\tilde{\boldsymbol{\beta}}_s]$$

$$\text{Cov}[\hat{\boldsymbol{\alpha}}, \tilde{\boldsymbol{\beta}}] = (\mathbf{Q}^{-1} \bar{\mathbf{Z}}' \mathbf{X}_s) \text{Var}[\tilde{\boldsymbol{\beta}}_s]$$

Now you work out the variance covariance estimates for the dummy variables.

Variance Covariance of Dummy variables with No Intercept

The variances and covariances of the dummy variables are given under the NOINT selection as follows:

$$\text{Cov}(D_i^C, D_j^C) = \text{Cov}(\hat{\gamma}_i, \hat{\gamma}_j) + \text{Cov}(\hat{\gamma}_i, \hat{\alpha}_T) + \text{Cov}(\hat{\gamma}_j, \hat{\alpha}_T) + \text{Var}(\hat{\alpha}_T)$$

$$\text{Cov}(D_t^T, D_u^T) = \text{Cov}(\hat{\alpha}_t, \hat{\alpha}_u) - \text{Cov}(\hat{\alpha}_t, \hat{\alpha}_T) - \text{Cov}(\hat{\alpha}_u, \hat{\alpha}_T) + \text{Var}(\hat{\alpha}_T)$$

$$\text{Cov}(D_i^C, D_t^T) = \text{Cov}(\hat{\gamma}_i, \hat{\alpha}_t) + \text{Cov}(\hat{\gamma}_i, \hat{\alpha}_T) - \text{Cov}(\hat{\gamma}_i, \hat{\alpha}_T) - \text{Var}(\hat{\alpha}_T)$$

$$\text{Cov}(D_i^C, \tilde{\boldsymbol{\beta}}) = -\text{Cov}(\hat{\gamma}_i, \tilde{\boldsymbol{\beta}}) - \text{Cov}(\hat{\alpha}_T, \tilde{\boldsymbol{\beta}})$$

$$\text{Cov}(D_t^T, \tilde{\boldsymbol{\beta}}) = -\text{Cov}(\hat{\alpha}_t, \tilde{\boldsymbol{\beta}}) + \text{Cov}(\hat{\alpha}_T, \tilde{\boldsymbol{\beta}})$$

Variance Covariance of Dummy variables with Intercept

The variances and covariances of the dummy variables are given as follows when the intercept is included:

$$\begin{aligned} \text{Cov} \left(D_i^C, D_j^C \right) &= \text{Cov} \left(\hat{\gamma}_i, \hat{\gamma}_j \right) - \text{Cov} \left(\hat{\gamma}_i, \hat{\gamma}_N \right) - \text{Cov} \left(\hat{\gamma}_j, \hat{\gamma}_N \right) + \text{Var} \left(\hat{\gamma}_N \right) \\ \text{Cov} \left(D_i^T, D_u^T \right) &= \text{Cov} \left(\hat{\alpha}_t, \hat{\alpha}_u \right) - \text{Cov} \left(\hat{\alpha}_t, \hat{\alpha}_T \right) - \text{Cov} \left(\hat{\alpha}_u, \hat{\alpha}_T \right) + \text{Var} \left(\hat{\alpha}_T \right) \\ \text{Cov} \left(D_i^C, D_i^T \right) &= \text{Cov} \left(\hat{\gamma}_i, \hat{\alpha}_t \right) - \text{Cov} \left(\hat{\gamma}_i, \hat{\alpha}_T \right) - \text{Cov} \left(\hat{\gamma}_N, \hat{\alpha}_t \right) + \text{Cov} \left(\hat{\gamma}_N, \hat{\alpha}_T \right) \\ \text{Cov} \left(D_i^C, \text{Intercept} \right) &= \text{Cov} \left(\hat{\gamma}_i, \hat{\gamma}_N \right) + \text{Cov} \left(\hat{\gamma}_i, \hat{\alpha}_T \right) - \text{Cov} \left(\hat{\gamma}_j, \hat{\alpha}_T \right) - \text{Var} \left(\hat{\gamma}_N \right) \\ \text{Cov} \left(D_i^T, \text{Intercept} \right) &= \text{Cov} \left(\hat{\alpha}_t, \hat{\alpha}_T \right) + \text{Cov} \left(\hat{\alpha}_t, \hat{\gamma}_N \right) - \text{Cov} \left(\hat{\alpha}_T, \hat{\alpha}_N \right) - \text{Var} \left(\hat{\alpha}_T \right) \\ \text{Cov} \left(D_i^C, \tilde{\beta} \right) &= -\text{Cov} \left(\hat{\gamma}_i, \tilde{\beta} \right) - \text{Cov} \left(\hat{\gamma}_N, \tilde{\beta} \right) \\ \text{Cov} \left(D_i^T, \tilde{\beta} \right) &= -\text{Cov} \left(\hat{\alpha}_t, \tilde{\beta} \right) + \text{Cov} \left(\hat{\alpha}_T, \tilde{\beta} \right) \\ \text{Cov} \left(\text{Intercept}, \tilde{\beta}_f \right) &= -\text{Cov} \left(\hat{\alpha}_T, \tilde{\beta} \right) - \text{Cov} \left(\hat{\gamma}_N, \tilde{\beta} \right) \end{aligned}$$

Between Estimators

The between groups estimator is the regression of the cross section means of \mathbf{y} on the cross section means of $\tilde{\mathbf{X}}_s$. In other words, you fit the following regression:

$$\bar{y}_i = \bar{\mathbf{x}}_i \beta^{BG} + \eta_i$$

The between time periods estimator is the regression of the time means of \mathbf{y} on the time means of $\tilde{\mathbf{X}}_s$. In other words, you fit the following regression:

$$\bar{y}_{.t} = \bar{\mathbf{x}}_{.t} \beta^{BT} + \zeta_t$$

In either case, the error is assumed to be normally distributed with mean zero and a constant variance.

Pooled Estimator

PROC PANEL allows you to pool time series cross-sectional data and run regressions on the data. Pooling is admissible if there are no fixed effects or random effects present in the data. This feature is included to aid in analysis and comparison across model types and to give you access to HCCME standard errors and other panel diagnostics. In general, this model type should not be used with time series cross-sectional data.

The One-Way Random-Effects Model

The specification for the one-way random-effects model is

$$u_{it} = v_i + \epsilon_{it}$$

Let $\mathbf{Z}_0 = \text{diag}(\mathbf{J}_{T_i})$, $\mathbf{P}_0 = \text{diag}(\bar{\mathbf{J}}_{T_i})$, and $\mathbf{Q}_0 = \text{diag}(\mathbf{E}_{T_i})$, with $\bar{\mathbf{J}}_{T_i} = \mathbf{J}_{T_i}/T_i$ and $\mathbf{E}_{T_i} = \mathbf{I}_{T_i} - \bar{\mathbf{J}}_{T_i}$. Define $\tilde{\mathbf{X}}_s = \mathbf{Q}_0\mathbf{X}_s$ and $\tilde{\mathbf{y}} = \mathbf{Q}_0\mathbf{y}$ and \mathbf{J} as a vector of ones T_i long.

In the one-way model, estimation proceeds in a two-step fashion. First, you obtain estimates of the variance of the σ_ϵ^2 and σ_v^2 . There are multiple ways to derive these estimates; PROC PANEL provides four options. All four options are valid for balanced or unbalanced panels. Once these estimates are in hand, they are used to form a weighting factor θ , and estimation proceeds via OLS on partial deviations from group means.

PROC PANEL gives the following options for variance component estimators.

Fuller and Battese's Method

The Fuller and Battese method for estimating variance components can be obtained with the option VCOMP = FB and the option RANONE. The variance components are given by the following equations (see Baltagi and Chang (1994) and Fuller and Battese (1974) for the approach in the two-way model). Let

$$R(v) = \mathbf{y}'\mathbf{Z}_0(\mathbf{Z}_0'\mathbf{Z}_0)^{-1}\mathbf{Z}_0'\mathbf{y}$$

$$R(\beta|v) = ((\tilde{\mathbf{X}}_s'\tilde{\mathbf{X}}_s)^{-1}\tilde{\mathbf{X}}_s'\tilde{\mathbf{y}})'(\tilde{\mathbf{X}}_s'\tilde{\mathbf{y}})$$

$$R(\beta) = (\mathbf{X}_s'\mathbf{y})'(\mathbf{X}_s'\mathbf{X}_s)^{-1}\mathbf{X}_s'\mathbf{y}$$

$$R(v|\beta) = R(\beta|v) + R(v) - R(\beta)$$

The estimator of the error variance is given by

$$\hat{\sigma}_\epsilon^2 = (\mathbf{y}'\mathbf{y} - R(\beta|v) - R(v))/(M - N - (K - 1))$$

If the NOINT option is specified, the estimator is

$$\hat{\sigma}_\epsilon^2 = (\mathbf{y}'\mathbf{y} - R(\beta|v) - R(v))/(M - N - K)$$

The estimator of the cross-sectional variance component is given by

$$\hat{\sigma}_v^2 = (R(v|\beta) - (N - 1)\hat{\sigma}_\epsilon^2)/(M - \text{tr}(\mathbf{Z}_0'\mathbf{X}_s(\mathbf{X}_s'\mathbf{X}_s)^{-1}\mathbf{X}_s'\mathbf{Z}_0))$$

Note that the error variance is the variance of the residual of the within estimator.

According to Baltagi and Chang (1994), the Fuller and Battese method is appropriate to apply to both balanced and unbalanced data. The Fuller and Battese method is the default for estimation of one-way random-effects models with balanced panels. However, the Fuller and Battese method does not always obtain nonnegative estimates for the cross section (or group) variance. In the case of a negative estimate, a warning is printed and the estimate is set to zero.

Wansbeek and Kapteyn's Method

The Wansbeek and Kapteyn method for estimating variance components can be obtained by setting $VCOMP = WK$ (together with the option $RANONE$). The estimation of the one-way unbalanced data model is performed by using a specialization (Baltagi and Chang 1994) of the approach used by Wansbeek and Kapteyn (1989) for unbalanced two-way models. The Wansbeek and Kapteyn method is the default for unbalanced data. If just $RANONE$ is specified, without the $VCOMP=$ option, $PROC PANEL$ estimates the variance component under Wansbeek and Kapteyn's method.

The estimation of the variance components is performed by using a quadratic unbiased estimation (QUE) method. This involves focusing on quadratic forms of the centered residuals, equating their expected values to the realized quadratic forms, and solving for the variance components.

Let

$$q_1 = \tilde{\mathbf{u}}' \mathbf{Q}_0 \tilde{\mathbf{u}}$$

$$q_2 = \tilde{\mathbf{u}}' \mathbf{P}_0 \tilde{\mathbf{u}}$$

where the residuals $\tilde{\mathbf{u}}$ are given by $\tilde{\mathbf{u}} = (\mathbf{I}_M - \mathbf{j}_M \mathbf{j}'_M / M)(\mathbf{y} - \mathbf{X}_s (\tilde{\mathbf{X}}'_s \tilde{\mathbf{X}}_s)^{-1} \tilde{\mathbf{X}}'_s \tilde{\mathbf{y}})$ if there is an intercept and by $\tilde{\mathbf{u}} = \mathbf{y} - \mathbf{X}_s (\tilde{\mathbf{X}}'_s \tilde{\mathbf{X}}_s)^{-1} \tilde{\mathbf{X}}'_s \tilde{\mathbf{y}}$ if there is not. A vector of M ones is represented by \mathbf{j} .

Consider the expected values

$$E(q_1) = (M - N - (K - 1))\sigma_\epsilon^2$$

$$E(q_2) = (N - 1 + \text{tr}[(\mathbf{X}'_s \mathbf{Q}_0 \mathbf{X}_s)^{-1} \mathbf{X}'_s \mathbf{P}_0 \mathbf{X}_s] - \text{tr}[(\mathbf{X}'_s \mathbf{Q}_0 \mathbf{X}_s)^{-1} \mathbf{X}'_s \bar{\mathbf{J}}_M \mathbf{X}_s])\sigma_\epsilon^2 \\ [M - (\sum_i T_i^2 / M)]\sigma_v^2$$

where $\hat{\sigma}_\epsilon^2$ and $\hat{\sigma}_v^2$ are obtained by equating the quadratic forms to their expected values.

The estimator of the error variance is the residual variance of the within estimate. The Wansbeek and Kapteyn method can also generate negative variance components estimates.

Wallace and Hussain's Method

The Wallace and Hussain method for estimating variance components can be obtained by setting $VCOMP = WH$ (together with the option $RANONE$). Wallace-Hussain estimates start from OLS residuals on a data that are assumed to exhibit groupwise heteroscedasticity. As in the Wansbeek and Kapteyn method, you start with

$$q_1 = \tilde{\mathbf{u}}'_{OLS} \mathbf{Q}_0 \tilde{\mathbf{u}}_{OLS}$$

$$q_2 = \tilde{\mathbf{u}}'_{OLS} \mathbf{P}_0 \tilde{\mathbf{u}}_{OLS}$$

However, instead of using the 'true' errors, you substitute the OLS residuals. You solve the system

$$E(\hat{q}_1) = E(\hat{\mathbf{u}}'_{OLS} \mathbf{Q}_0 \hat{\mathbf{u}}_{OLS}) = \delta_{11} \hat{\sigma}_v^2 + \delta_{12} \hat{\sigma}_\epsilon^2$$

$$E(\hat{q}_2) = E(\hat{\mathbf{u}}'_{OLS} \mathbf{P}_0 \hat{\mathbf{u}}_{OLS}) = \delta_{21} \hat{\sigma}_v^2 + \delta_{22} \hat{\sigma}_\epsilon^2$$

The constants δ_{11} , δ_{12} , δ_{21} , δ_{22} are given by

$$\delta_{11} = \text{tr} \left(\left(\mathbf{X}'\mathbf{X} \right)^{-1} \mathbf{X}'\mathbf{Z}_0\mathbf{Z}_0'\mathbf{X} \right) - \text{tr} \left(\left(\mathbf{X}'\mathbf{X} \right)^{-1} \mathbf{X}'\mathbf{P}_0\mathbf{X} \left(\mathbf{X}'\mathbf{X} \right)^{-1} \mathbf{X}'\mathbf{Z}_0\mathbf{Z}_0'\mathbf{X} \right)$$

$$\delta_{12} = M - N - K + \text{tr} \left(\left(\mathbf{X}'\mathbf{X} \right)^{-1} \mathbf{X}'\mathbf{P}_0\mathbf{X} \right)$$

$$\delta_{21} = M - 2tr \left(\left(\mathbf{X}'\mathbf{X} \right)^{-1} \mathbf{X}'\mathbf{Z}_0\mathbf{Z}_0'\mathbf{X} \right) + \text{tr} \left(\left(\mathbf{X}'\mathbf{X} \right)^{-1} \mathbf{X}'\mathbf{P}_0\mathbf{X} \right)$$

$$\delta_{22} = N - \text{tr} \left(\left(\mathbf{X}'\mathbf{X} \right)^{-1} \mathbf{X}'\mathbf{P}_0\mathbf{X} \right)$$

where $\text{tr}()$ is the trace operator on a square matrix.

Solving this system produces the variance components. This method is applicable to balanced and unbalanced panels. However, there is no guarantee of positive variance components. Any negative values are fixed equal to zero.

Nerlove's Method

The Nerlove method for estimating variance components can be obtained by setting $\text{VCOMP} = \text{NL}$. The Nerlove method (see Baltagi 1995, page 17) is assured to give estimates of the variance components that are always positive. Furthermore, it is simple in contrast to the previous estimators.

If γ_i is the i th fixed effect, Nerlove's method uses the variance of the fixed effects as the estimate of $\hat{\sigma}_v^2$. You have $\hat{\sigma}_v^2 = \sum_{i=1}^N \frac{(\gamma_i - \bar{\gamma})^2}{N-1}$, where $\bar{\gamma}$ is the mean fixed effect. The estimate of σ_ϵ^2 is simply the residual sum of squares of the one-way fixed-effects regression divided by the number of observations.

With the variance components in hand, from any method, the next task is to estimate the regression model of interest. For each individual, you form a weight (θ_i) as follows:

$$\theta_i = 1 - \sigma_\epsilon / w_i$$

$$w_i^2 = T_i \sigma_v^2 + \sigma_\epsilon^2$$

where T_i is the i th cross section's time observations.

Taking the θ_i , you form the partial deviations,

$$\tilde{y}_{it} = y_{it} - \theta_i \bar{y}_i.$$

$$\tilde{x}_{it} = x_{it} - \theta_i \bar{x}_i.$$

where \bar{y}_i and \bar{x}_i are cross section means of the dependent variable and independent variables (including the constant if any), respectively.

The random-effects β is then the result of simple OLS on the transformed data.

The Two-Way Random-Effects Model

The specification for the two-way random-effects model is

$$u_{it} = v_i + e_t + \epsilon_{it}$$

As in the one-way random-effects model, the PANEL procedure provides four options for variance component estimators. Unlike the one-way random-effects model, unbalanced panels present some special concerns.

Let \mathbf{X}_* and \mathbf{y}_* be the independent and dependent variables arranged by time and by cross section within each time period. (Note that the input data set used by the PANEL procedure must be sorted by cross section and then by time within each cross section.) Let M_t be the number of cross sections observed in time t and $\sum_t M_t = M$. Let \mathbf{D}_t be the $M_t \times N$ matrix obtained from the $N \times N$ identity matrix from which rows that correspond to cross sections not observed at time t have been omitted. Consider

$$\mathbf{Z} = (\mathbf{Z}_1, \mathbf{Z}_2)$$

where $\mathbf{Z}_1 = (\mathbf{D}'_1, \mathbf{D}'_2, \dots, \mathbf{D}'_T)'$ and $\mathbf{Z}_2 = \text{diag}(\mathbf{D}_1 \mathbf{j}_N, \mathbf{D}_2 \mathbf{j}_N, \dots, \mathbf{D}_T \mathbf{j}_N)$.

The matrix \mathbf{Z} gives the dummy variable structure for the two-way model.

For notational ease, let

$$\Delta_N = \mathbf{Z}'_1 \mathbf{Z}_1, \Delta_T = \mathbf{Z}'_2 \mathbf{Z}_2, \mathbf{A} = \mathbf{Z}'_2 \mathbf{Z}_1$$

$$\bar{\mathbf{Z}} = \mathbf{Z}_2 - \mathbf{Z}_1 \Delta_N^{-1} \mathbf{A}'$$

$$\bar{\Delta}_1 = \mathbf{I}_M - \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}'_1$$

$$\bar{\Delta}_2 = \mathbf{I}_M - \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}'_2$$

$$\mathbf{Q} = \Delta_T - \mathbf{A} \Delta_N^{-1} \mathbf{A}'$$

$$\mathbf{P} = (\mathbf{I}_M - \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}'_1) - \bar{\mathbf{Z}} \mathbf{Q}^{-1} \bar{\mathbf{Z}}'$$

Fuller and Battese's Method

The Fuller and Battese method for estimating variance components can be obtained by setting VCOMP = FB (with the option RANTWO). FB is the default method for a RANTWO model with balanced panel. If RANTWO is requested without specifying the VCOMP= option, PROC PANEL proceeds under the Fuller and Battese method.

Following the discussion in Baltagi, et. al. (2002), the Fuller and Battese method forms the estimates as follows.

The estimator of the error variance is

$$\hat{\sigma}_\epsilon^2 = \tilde{\mathbf{u}}' \mathbf{P} \tilde{\mathbf{u}} / (M - T - N + 1 - (K - 1))$$

where \mathbf{P} is the Wansbeek and Kapteyn within estimator for unbalanced (or balanced) panel in a two-way setting.

The estimator of the error variance is the same as that in the Wansbeek and Kapteyn method.

Consider the expected values

$$\begin{aligned} E(q_N) &= \sigma_\epsilon^2 [M - T - K + 1] \\ &+ \sigma_v^2 \left[M - T - \text{tr} \left(\mathbf{X}'_s \bar{\Delta}_2 \mathbf{Z}_1 \mathbf{Z}'_1 \bar{\Delta}_2 \mathbf{X}_s \left(\mathbf{X}'_s \bar{\Delta}_2 \mathbf{X}_s \right)^{-1} \right) \right] \\ E(q_T) &= \sigma_\epsilon^2 [M - N - K + 1] \\ &+ \sigma_e^2 \left[M - N - \text{tr} \left(\mathbf{X}'_s \bar{\Delta}_1 \mathbf{Z}_2 \mathbf{Z}'_2 \bar{\Delta}_1 \mathbf{X}_s \left(\mathbf{X}'_s \bar{\Delta}_1 \mathbf{X}_s \right)^{-1} \right) \right] \end{aligned}$$

Just as in the one-way case, there is always the possibility that the (estimated) variance components will be negative. In such a case, the negative components are fixed to equal zero. After substituting the group sum of the within residuals for (q_N) , the time sums of the within residuals for (q_T) , and $\hat{\sigma}_\epsilon^2$, the two equations are solved for $\hat{\sigma}_v^2$ and $\hat{\sigma}_e^2$.

Wansbeek and Kapteyn's Method

The Wansbeek and Kapteyn method for estimating variance components can be obtained by setting VCOMP = WK. The following methodology, outlined in Wansbeek and Kapteyn (1989) is used to handle both balanced and unbalanced data. The Wansbeek and Kapteyn method is the default for a RANTWO model with unbalanced panel. If RANTWO is requested without specifying the VCOMP= option, PROC PANEL proceeds under the Wansbeek and Kapteyn method if the panel is unbalanced.

The estimator of the error variance is

$$\hat{\sigma}_\epsilon^2 = \tilde{\mathbf{u}}' \mathbf{P} \tilde{\mathbf{u}} / (M - T - N + 1 - (K - 1))$$

where the $\tilde{\mathbf{u}}$ are given by $\tilde{\mathbf{u}} = (\mathbf{I}_M - \mathbf{j}_M \mathbf{j}'_M / M)(\mathbf{y}_* - \mathbf{X}_{*s} (\mathbf{X}'_{*s} \mathbf{P} \mathbf{X}_{*s})^{-1} \mathbf{X}'_{*s} \mathbf{P} \mathbf{y}_*)$ if there is an intercept and by $\tilde{\mathbf{u}} = (\mathbf{y}_* - \mathbf{X}_{*s} (\mathbf{X}'_{*s} \mathbf{P} \mathbf{X}_{*s})^{-1} \mathbf{X}'_{*s} \mathbf{P} \mathbf{y}_*)$ if there is not.

The estimation of the variance components is performed by using a quadratic unbiased estimation (QUE) method that involves computing on quadratic forms of the residuals $\tilde{\mathbf{u}}$, equating their expected values to the realized quadratic forms, and solving for the variance components.

Let

$$q_N = \tilde{\mathbf{u}}' \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}'_2 \tilde{\mathbf{u}}$$

$$q_T = \tilde{\mathbf{u}}' \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}'_1 \tilde{\mathbf{u}}$$

The expected values are

$$E(q_N) = (T + k_N - (1 + k_0))\sigma^2 + (T - \frac{\lambda_1}{M})\sigma_v^2 + (M - \frac{\lambda_2}{M})\sigma_e^2$$

$$E(q_T) = (N + k_T - (1 + k_0))\sigma^2 + \left(M - \frac{\lambda_1}{M}\right)\sigma_v^2 + \left(N - \frac{\lambda_2}{M}\right)\sigma_e^2$$

where

$$\begin{aligned} k_0 &= \mathbf{j}'_M \mathbf{X}_{*s} (\mathbf{X}'_{*s} \mathbf{P} \mathbf{X}_{*s})^{-1} \mathbf{X}'_{*s} \mathbf{j}_M / M \\ k_N &= \text{tr}((\mathbf{X}'_{*s} \mathbf{P} \mathbf{X}_{*s})^{-1} \mathbf{X}'_{*s} \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}'_2 \mathbf{X}_{*s}) \\ k_T &= \text{tr}((\mathbf{X}'_{*s} \mathbf{P} \mathbf{X}_{*s})^{-1} \mathbf{X}'_{*s} \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}'_1 \mathbf{X}_{*s}) \\ \lambda_1 &= \mathbf{j}'_M \mathbf{Z}_1 \mathbf{Z}'_1 \mathbf{j}_M \\ \lambda_2 &= \mathbf{j}'_M \mathbf{Z}_2 \mathbf{Z}'_2 \mathbf{j}_M \end{aligned}$$

The quadratic unbiased estimators for σ_v^2 and σ_e^2 are obtained by equating the expected values to the quadratic forms and solving for the two unknowns.

When the NOINT option is specified, the variance component equations change slightly. In particular, the following is true (Wansbeek and Kapteyn 1989):

$$\begin{aligned} E(q_N) &= (T + k_N)\sigma^2 + T\sigma_v^2 + M\sigma_e^2 \\ E(q_T) &= (N + k_T)\sigma^2 + M\sigma_v^2 + N\sigma_e^2 \end{aligned}$$

Wallace and Hussain's Method

The Wallace and Hussain method for estimating variance components can be obtained by setting VCOMP = WH. Wallace and Hussain's method is by far the most computationally intensive. It uses the OLS residuals to estimate the variance components. In other words, the Wallace and Hussain method assumes that the following holds:

$$\begin{aligned} q_\epsilon &= \tilde{\mathbf{u}}'_{OLS} \mathbf{P} \tilde{\mathbf{u}}_{OLS} \\ q_N &= \tilde{\mathbf{u}}'_{OLS} \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}'_2 \tilde{\mathbf{u}}_{OLS} \\ q_T &= \tilde{\mathbf{u}}'_{OLS} \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}'_1 \tilde{\mathbf{u}}_{OLS} \end{aligned}$$

Taking expectations yields

$$\begin{aligned} E(q_\epsilon) &= E\left(\tilde{\mathbf{u}}'_{OLS} \mathbf{P} \tilde{\mathbf{u}}_{OLS}\right) = \delta_{11}\sigma_\epsilon^2 + \delta_{12}\sigma_v^2 + \delta_{13}\sigma_e^2 \\ E(q_N) &= E\left(\tilde{\mathbf{u}}'_{OLS} \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}'_2 \tilde{\mathbf{u}}_{OLS}\right) = \delta_{21}\sigma_\epsilon^2 + \delta_{22}\sigma_v^2 + \delta_{23}\sigma_e^2 \\ E(q_T) &= E\left(\tilde{\mathbf{u}}'_{OLS} \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}'_1 \tilde{\mathbf{u}}_{OLS}\right) = \delta_{31}\sigma_\epsilon^2 + \delta_{32}\sigma_v^2 + \delta_{33}\sigma_e^2 \end{aligned}$$

where the δ_{js} constants are defined by

$$\delta_{11} = M - N - T + 1 - \text{tr}\left(\mathbf{X}' \mathbf{P} \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1}\right)$$

$$\delta_{12} = \text{tr} \left(\mathbf{X}' \mathbf{Z}_1 \mathbf{Z}_1' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \left(\mathbf{X}' \mathbf{P} \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \right)$$

$$\delta_{13} = \text{tr} \left(\mathbf{X}' \mathbf{Z}_2 \mathbf{Z}_2' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \left(\mathbf{X}' \mathbf{P} \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \right)$$

$$\delta_{21} = T - \text{tr} \left(\mathbf{X}' \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}_2' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right)$$

$$\begin{aligned} \delta_{22} &= T - 2\text{tr} \left(\mathbf{X}' \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}_2' \mathbf{Z}_1 \mathbf{Z}_1' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \\ &\quad + \text{tr} \left(\mathbf{X}' \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}_2' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \mathbf{X}' \mathbf{Z}_1 \mathbf{Z}_1' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \end{aligned}$$

$$\begin{aligned} \delta_{23} &= T - 2\text{tr} \left(\mathbf{X}' \mathbf{Z}_2 \mathbf{Z}_2' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \\ &\quad + \text{tr} \left(\mathbf{X}' \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}_2' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \mathbf{X}' \mathbf{Z}_2 \mathbf{Z}_2' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \end{aligned}$$

$$\delta_{31} = N - \text{tr} \left(\mathbf{X}' \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}_1' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right)$$

$$\begin{aligned} \delta_{32} &= M - 2\text{tr} \left(\mathbf{X}' \mathbf{Z}_1 \mathbf{Z}_1' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \\ &\quad + \text{tr} \left(\mathbf{X}' \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}_1' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \mathbf{X}' \mathbf{Z}_1 \mathbf{Z}_1' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \end{aligned}$$

$$\begin{aligned} \delta_{33} &= N - 2\text{tr} \left(\mathbf{X}' \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}_1' \mathbf{Z}_2 \mathbf{Z}_2' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \\ &\quad + \text{tr} \left(\mathbf{X}' \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}_1' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \mathbf{X}' \mathbf{Z}_2 \mathbf{Z}_2' \mathbf{X} (\mathbf{X}' \mathbf{X})^{-1} \right) \end{aligned}$$

The PANEL procedure solves this system for the estimates $\hat{\sigma}_\epsilon$, $\hat{\sigma}_v$, and $\hat{\sigma}_e$. Some of the estimated variance components can be negative. Negative components are set to zero and estimation proceeds.

Nerlove's Method

The Nerlove method for estimating variance components can be obtained with by setting VCOMP = NL.

The estimator of the error variance is

$$\hat{\sigma}_\epsilon^2 = \tilde{\mathbf{u}}' \mathbf{P} \tilde{\mathbf{u}} / M$$

The variance components for cross section and time effects are:

$$\hat{\sigma}_v^2 = \sum_{i=1}^N \frac{(\gamma_i - \bar{\gamma})^2}{N-1} \text{ where } \gamma_i \text{ is the } i\text{th cross section effect}$$

and

$$\hat{\sigma}_e^2 = \sum_{t=1}^T \frac{(\alpha_t - \bar{\alpha})^2}{T-1} \text{ where } \alpha_t \text{ is the } t\text{th time effect}$$

With the estimates of the variance components in hand, you can proceed to the final estimation. If the panel is balanced, partial mean deviations are used:

$$\tilde{y}_{it} = y_{it} - \theta_1 \bar{y}_i - \theta_2 \bar{y}_{\cdot t} + \theta_3 \bar{y}_{\cdot\cdot}$$

$$\tilde{x}_{it} = x_{it} - \theta_1 \bar{x}_i - \theta_2 \bar{x}_{\cdot t} + \theta_3 \bar{x}_{\cdot\cdot}$$

The θ estimates are obtained from

$$\begin{aligned} \theta_1 &= 1 - \frac{\sigma_\epsilon}{\sqrt{T\sigma_v^2 + \sigma_\epsilon^2}} \\ \theta_2 &= 1 - \frac{\sigma_\epsilon}{\sqrt{N\sigma_e^2 + \sigma_\epsilon^2}} \\ \theta_3 &= \theta_1 + \theta_2 + \frac{\sigma_\epsilon}{\sqrt{T\sigma_v^2 + N\sigma_e^2 + \sigma_\epsilon^2}} - 1; \end{aligned}$$

With these partial deviations, PROC PANEL uses OLS on the transformed series (including an intercept if so desired).

The case of an unbalanced panel is somewhat trickier. You could naively substitute the variance components in the equation below:

$$\Omega = \sigma_\epsilon^2 \mathbf{I}_M + \sigma_v^2 \mathbf{Z}_1 \mathbf{Z}_1' + \sigma_e^2 \mathbf{Z}_2 \mathbf{Z}_2'$$

After inverting the expression for Ω , it is possible to do GLS on the data (even if the panel is unbalanced). However, the inversion of Ω is no small matter because the dimension is at least $\frac{M(M+1)}{2}$.

Wansbeek and Kapteyn show that the inverse of Ω can be written as

$$\sigma_\epsilon^2 \Omega^{-1} = \mathbf{V} - \mathbf{VZ}_2 \tilde{\mathbf{P}}^{-1} \mathbf{Z}_2' \mathbf{V}$$

with the following:

$$\begin{aligned} \mathbf{V} &= \mathbf{I}_M - \mathbf{Z}_1 \tilde{\Delta}_N^{-1} \mathbf{Z}_1' \\ \tilde{\mathbf{P}} &= \tilde{\Delta}_T - \mathbf{A} \tilde{\Delta}_N^{-1} \mathbf{A}' \\ \tilde{\Delta}_N &= \Delta_N + \begin{pmatrix} \sigma_\epsilon^2 \\ \sigma_v^2 \end{pmatrix} \mathbf{I}_N \\ \tilde{\Delta}_T &= \Delta_T + \begin{pmatrix} \sigma_\epsilon^2 \\ \sigma_e^2 \end{pmatrix} \mathbf{I}_T \end{aligned}$$

Computationally, this is a much less intensive approach.

By using the inverse of the variance-covariance matrix of the error, it becomes possible to complete GLS on the unbalanced panel.

Parks Method (Autoregressive Model)

Parks (1967) considered the first-order autoregressive model in which the random errors u_{it} , $i = 1, 2, \dots, N$, and $t = 1, 2, \dots, T$ have the structure

$$\begin{aligned} E(u_{it}^2) &= \sigma_{ii} \text{(heteroscedasticity)} \\ E(u_{it}u_{jt}) &= \sigma_{ij} \text{(contemporaneously correlated)} \\ u_{it} &= \rho_i u_{i,t-1} + \epsilon_{it} \text{(autoregression)} \end{aligned}$$

where

$$\begin{aligned} E(\epsilon_{it}) &= 0 \\ E(u_{i,t-1}\epsilon_{jt}) &= 0 \\ E(\epsilon_{it}\epsilon_{jt}) &= \phi_{ij} \\ E(\epsilon_{it}\epsilon_{js}) &= 0 (s \neq t) \\ E(u_{i0}) &= 0 \\ E(u_{i0}u_{j0}) &= \sigma_{ij} = \phi_{ij}/(1 - \rho_i\rho_j) \end{aligned}$$

The model assumed is first-order autoregressive with contemporaneous correlation between cross sections. In this model, the covariance matrix for the vector of random errors \mathbf{u} can be expressed as

$$E(\mathbf{uu}') = \mathbf{V} = \begin{bmatrix} \sigma_{11}P_{11} & \sigma_{12}P_{12} & \dots & \sigma_{1N}P_{1N} \\ \sigma_{21}P_{21} & \sigma_{22}P_{22} & \dots & \sigma_{2N}P_{2N} \\ \vdots & \vdots & \vdots & \vdots \\ \sigma_{N1}P_{N1} & \sigma_{N2}P_{N2} & \dots & \sigma_{NN}P_{NN} \end{bmatrix}$$

where

$$P_{ij} = \begin{bmatrix} 1 & \rho_j & \rho_j^2 & \dots & \rho_j^{T-1} \\ \rho_i & 1 & \rho_j & \dots & \rho_j^{T-2} \\ \rho_i^2 & \rho_i & 1 & \dots & \rho_j^{T-3} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \rho_i^{T-1} & \rho_i^{T-2} & \rho_i^{T-3} & \dots & 1 \end{bmatrix}$$

The matrix \mathbf{V} is estimated by a two-stage procedure, and $\boldsymbol{\beta}$ is then estimated by generalized least squares. The first step in estimating \mathbf{V} involves the use of ordinary least squares to estimate $\boldsymbol{\beta}$ and obtain the fitted residuals, as follows:

$$\hat{\mathbf{u}} = \mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}}_{OLS}$$

A consistent estimator of the first-order autoregressive parameter is then obtained in the usual manner, as follows:

$$\hat{\rho}_i = \left(\sum_{t=2}^T \hat{u}_{it} \hat{u}_{i,t-1} \right) / \left(\sum_{t=2}^T \hat{u}_{i,t-1}^2 \right) \quad i = 1, 2, \dots, N$$

Finally, the autoregressive characteristic of the data is removed (asymptotically) by the usual transformation of taking weighted differences. That is, for $i = 1, 2, \dots, N$,

$$y_{i1} \sqrt{1 - \hat{\rho}_i^2} = \sum_{k=1}^p X_{i1k} \beta_k \sqrt{1 - \hat{\rho}_i^2} + u_{i1} \sqrt{1 - \hat{\rho}_i^2}$$

$$y_{it} - \hat{\rho}_i y_{i,t-1} = \sum_{k=1}^p (X_{itk} - \hat{\rho}_i X_{i,t-1,k}) \beta_k + u_{it} - \hat{\rho}_i u_{i,t-1} \quad t = 2, \dots, T$$

which is written

$$y_{it}^* = \sum_{k=1}^p X_{itk}^* \beta_k + u_{it}^* \quad i = 1, 2, \dots, N; \quad t = 1, 2, \dots, T$$

Notice that the transformed model has not lost any observations (Seely and Zyskind 1971).

The second step in estimating the covariance matrix \mathbf{V} is applying ordinary least squares to the preceding transformed model, obtaining

$$\hat{\mathbf{u}}^* = \mathbf{y}^* - \mathbf{X}^* \hat{\boldsymbol{\beta}}_{OLS}^*$$

from which the consistent estimator of σ_{ij} is calculated as follows:

$$s_{ij} = \frac{\hat{\phi}_{ij}}{(1 - \hat{\rho}_i \hat{\rho}_j)}$$

where

$$\hat{\phi}_{ij} = \frac{1}{(T-p)} \sum_{t=1}^T \hat{u}_{it}^* \hat{u}_{jt}^*$$

Estimated generalized least squares (EGLS) then proceeds in the usual manner,

$$\hat{\boldsymbol{\beta}}_P = (\mathbf{X}' \hat{\mathbf{V}}^{-1} \mathbf{X})^{-1} \mathbf{X}' \hat{\mathbf{V}}^{-1} \mathbf{y}$$

where $\hat{\mathbf{V}}$ is the derived consistent estimator of \mathbf{V} . For computational purposes, $\hat{\boldsymbol{\beta}}_P$ is obtained directly from the transformed model,

$$\hat{\boldsymbol{\beta}}_P = (\mathbf{X}^{*'} (\hat{\Phi}^{-1} \otimes I_T) \mathbf{X}^*)^{-1} \mathbf{X}^{*'} (\hat{\Phi}^{-1} \otimes I_T) \mathbf{y}^*$$

where $\hat{\Phi} = [\hat{\phi}_{ij}]_{i,j=1,\dots,N}$.

The preceding procedure is equivalent to Zellner's two-stage methodology applied to the transformed model (Zellner 1962).

Parks demonstrates that this estimator is consistent and asymptotically, normally distributed with

$$\text{Var}(\hat{\boldsymbol{\beta}}_P) = (\mathbf{X}' \mathbf{V}^{-1} \mathbf{X})^{-1}$$

Standard Corrections

For the PARKS option, the first-order autocorrelation coefficient must be estimated for each cross section. Let ρ be the $N \times 1$ vector of true parameters and $R = (r_1, \dots, r_N)'$ be the corresponding vector of estimates. Then, to ensure that only range-preserving estimates are used in PROC PANEL, the following modification for R is made:

$$r_i = \begin{cases} r_i & \text{if } |r_i| < 1 \\ \max(.95, r_{\max}) & \text{if } r_i \geq 1 \\ \min(-.95, r_{\min}) & \text{if } r_i \leq -1 \end{cases}$$

where

$$r_{\max} = \begin{cases} 0 & \text{if } r_i < 0 \text{ or } r_i \geq 1 \quad \forall i \\ \max_j[r_j : 0 \leq r_j < 1] & \text{otherwise} \end{cases}$$

and

$$r_{\min} = \begin{cases} 0 & \text{if } r_i > 0 \text{ or } r_i \leq -1 \quad \forall i \\ \max_j[r_j : -1 < r_j \leq 0] & \text{otherwise} \end{cases}$$

Whenever this correction is made, a warning message is printed.

Da Silva Method (Variance-Component Moving Average Model)

The Da Silva method assumes that the observed value of the dependent variable at the t th time point on the i th cross-sectional unit can be expressed as

$$y_{it} = \mathbf{x}'_{it}\beta + a_i + b_t + e_{it} \quad i = 1, \dots, N; t = 1, \dots, T$$

where

$\mathbf{x}'_{it} = (x_{it1}, \dots, x_{itp})$ is a vector of explanatory variables for the t th time point and i th cross-sectional unit

$\beta = (\beta_1, \dots, \beta_p)'$ is the vector of parameters

a_i is a time-invariant, cross-sectional unit effect

b_t is a cross-sectionally invariant time effect

e_{it} is a residual effect unaccounted for by the explanatory variables and the specific time and cross-sectional unit effects

Since the observations are arranged first by cross sections, then by time periods within cross sections, these equations can be written in matrix notation as

$$\mathbf{y} = \mathbf{X}\beta + \mathbf{u}$$

where

$$\begin{aligned} \mathbf{u} &= (\mathbf{a} \otimes \mathbf{1}_T) + (\mathbf{1}_N \otimes \mathbf{b}) + \mathbf{e} \\ \mathbf{y} &= (y_{11}, \dots, y_{1T}, y_{21}, \dots, y_{NT})' \\ \mathbf{X} &= (\mathbf{x}_{11}, \dots, \mathbf{x}_{1T}, \mathbf{x}_{21}, \dots, \mathbf{x}_{NT})' \\ \mathbf{a} &= (a_1 \dots a_N)' \\ \mathbf{b} &= (b_1 \dots b_T)' \\ \mathbf{e} &= (e_{11}, \dots, e_{1T}, e_{21}, \dots, e_{NT})' \end{aligned}$$

Here $\mathbf{1}_N$ is an $N \times 1$ vector with all elements equal to 1, and \otimes denotes the Kronecker product.

The following conditions are assumed:

1. \mathbf{x}_{it} is a sequence of nonstochastic, known $p \times 1$ vectors in \mathfrak{R}^p whose elements are uniformly bounded in \mathfrak{R}^p . The matrix \mathbf{X} has a full column rank p .
2. $\boldsymbol{\beta}$ is a $p \times 1$ constant vector of unknown parameters.
3. \mathbf{a} is a vector of uncorrelated random variables such that $E(a_i) = 0$ and $\text{var}(a_i) = \sigma_a^2$, $\sigma_a^2 > 0, i = 1, \dots, N$.
4. \mathbf{b} is a vector of uncorrelated random variables such that $E(b_t) = 0$ and $\text{var}(b_t) = \sigma_b^2$ where $\sigma_b^2 > 0$ and $t = 1, \dots, T$.
5. $\mathbf{e}_i = (e_{i1}, \dots, e_{iT})'$ is a sample of a realization of a finite moving-average time series of order $m < T - 1$ for each i ; hence,

$$e_{it} = \alpha_0 \epsilon_t + \alpha_1 \epsilon_{t-1} + \dots + \alpha_m \epsilon_{t-m} \quad t = 1, \dots, T; i = 1, \dots, N$$

where $\alpha_0, \alpha_1, \dots, \alpha_m$ are unknown constants such that $\alpha_0 \neq 0$ and $\alpha_m \neq 0$, and $\{\epsilon_j\}_{j=-\infty}^{j=\infty}$ is a white noise process—that is, a sequence of uncorrelated random variables with $E(\epsilon_t) = 0, E(\epsilon_t^2) = \sigma_\epsilon^2$, and $\sigma_\epsilon^2 > 0$.

6. The sets of random variables $\{a_i\}_{i=1}^N, \{b_t\}_{t=1}^T$, and $\{e_{it}\}_{t=1}^T$ for $i = 1, \dots, N$ are mutually uncorrelated.
7. The random terms have normal distributions $a_i \sim N(0, \sigma_a^2), b_t \sim N(0, \sigma_b^2)$, and $\epsilon_{t-k} \sim N(0, \sigma_\epsilon^2)$, for $i = 1, \dots, N; t = 1, \dots, T$; and $k = 1, \dots, m$.

If assumptions 1–6 are satisfied, then

$$E(\mathbf{y}) = \mathbf{X}\boldsymbol{\beta}$$

and

$$\text{var}(\mathbf{y}) = \sigma_a^2(I_N \otimes J_T) + \sigma_b^2(J_N \otimes I_T) + (I_N \otimes \Psi_T)$$

where Ψ_T is a $T \times T$ matrix with elements ψ_{ts} as follows:

$$\text{Cov}(e_{it}e_{is}) = \begin{cases} \psi(|t-s|) & \text{if } |t-s| \leq m \\ 0 & \text{if } |t-s| > m \end{cases}$$

where $\psi(k) = \sigma_\epsilon^2 \sum_{j=0}^{m-k} \alpha_j \alpha_{j+k}$ for $k = |t-s|$. For the definition of I_N , I_T , J_N , and J_T , see the section “Fuller and Battese’s Method” on page 1340.

The covariance matrix, denoted by \mathbf{V} , can be written in the form

$$\mathbf{V} = \sigma_a^2(I_N \otimes J_T) + \sigma_b^2(J_N \otimes I_T) + \sum_{k=0}^m \psi(k)(I_N \otimes \Psi_T^{(k)})$$

where $\Psi_T^{(0)} = I_T$, and, for $k=1, \dots, m$, $\Psi_T^{(k)}$ is a band matrix whose k th off-diagonal elements are 1’s and all other elements are 0’s.

Thus, the covariance matrix of the vector of observations \mathbf{y} has the form

$$\text{Var}(\mathbf{y}) = \sum_{k=1}^{m+3} v_k V_k$$

where

$$\begin{aligned} v_1 &= \sigma_a^2 \\ v_2 &= \sigma_b^2 \\ v_k &= \psi(k-3)k = 3, \dots, m+3 \\ V_1 &= I_N \otimes J_T \\ V_2 &= J_N \otimes I_T \\ V_k &= I_N \otimes \Psi_T^{(k-3)}k = 3, \dots, m+3 \end{aligned}$$

The estimator of $\boldsymbol{\beta}$ is a two-step GLS-type estimator—that is, GLS with the unknown covariance matrix replaced by a suitable estimator of \mathbf{V} . It is obtained by substituting Seely estimates for the scalar multiples v_k , $k = 1, 2, \dots, m+3$.

Seely (1969) presents a general theory of unbiased estimation when the choice of estimators is restricted to finite dimensional vector spaces, with a special emphasis on quadratic estimation of functions of the form $\sum_{i=1}^n \delta_i v_i$.

The parameters v_i ($i=1, \dots, n$) are associated with a linear model $E(\mathbf{y}) = \mathbf{X}\boldsymbol{\beta}$ with covariance matrix $\sum_{i=1}^n v_i V_i$ where V_i ($i=1, \dots, n$) are real symmetric matrices. The method is also discussed by Seely (1970a, 1970b) and Seely and Zyskind (1971). Seely and Soong (1971) consider the MINQUE principle, using an approach along the lines of Seely (1969).

Dynamic Panel Estimator

For an example on dynamic panel estimation using GMM option, see “Example 19.6: The Cigarette Sales Data: Dynamic Panel Estimation with GMM” on page 1390.

Consider the case of the following general model:

$$y_{it} = \sum_{l=1}^{maxlag} \phi_l y_{i(t-l)} + \sum_{k=1}^K \beta_k x_{itk} + \gamma_i + \alpha_t + \epsilon_{it}$$

The x variables can include ones that are correlated or uncorrelated to the individual effects, pre-determined, or strictly exogenous. The γ and α are cross-sectional and time series fixed effects, respectively. Arellano and Bond (1991) show that it is possible to define conditions that should result in a consistent estimator.

Consider the simple case of an autoregression in a panel setting (with only individual effects):

$$y_{it} = \phi y_{i(t-1)} + \gamma_i + \epsilon_{it}$$

Differencing the preceding relationship results in:

$$\Delta y_{it} = \phi \Delta y_{i(t-1)} + v_{it}$$

where $v_{it} = \epsilon_{it} - \epsilon_{it-1}$.

Obviously, y is not exogenous. However, Arellano and Bond (1991) show that it is still useful as an instrument, if properly lagged.

For $t = 2$ (assuming the first observation corresponds to time period 1) you have,

$$\Delta y_{i2} = \phi \Delta y_{i1} + v_{i2}$$

Using y_{i1} as an instrument is not a good idea since $\text{Cov}(\epsilon_{i1}, v_{i2}) \neq 0$. Therefore, since it is not possible to form a moment restriction, you discard this observation.

For $t = 3$ you have,

$$\Delta y_{i3} = \phi \Delta y_{i2} + v_{i3}$$

Clearly, you have every reason to suspect that $\text{Cov}(\epsilon_{i1}, v_{i3}) = 0$. This condition forms one restriction.

For $t = 4$, both $\text{Cov}(\epsilon_{i1}, v_{i4}) = 0$ and $\text{Cov}(\epsilon_{i2}, v_{i4}) = 0$ must hold.

Proceeding in that fashion, you have the following matrix of instruments,

$$\mathbf{Z}_i = \begin{pmatrix} y_{i1} & 0 & 0 & \cdots & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & y_{i1} & y_{i2} & 0 & \cdots & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & y_{i1} & y_{i2} & y_{i3} & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & & & & \vdots & & \vdots & \vdots \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & y_{i1} & \cdots & y_{i(T-2)} \end{pmatrix}$$

Using the instrument matrix, you form the weighting matrix \mathbf{A}_N as

$$\mathbf{A}_N = \left(\frac{1}{N} \sum_i \mathbf{Z}_i' \mathbf{H}_i \mathbf{Z}_i \right)^{-1}$$

The initial weighting matrix is

$$\mathbf{H}_i = \begin{pmatrix} 2 & -1 & 0 & \cdots & 0 & 0 & 0 & 0 & 0 & 0 \\ -1 & 2 & -1 & 0 & \cdots & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 2 & -1 & 0 & \cdots & 0 & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & & & & \vdots & & \vdots & \vdots \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 2 & -1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 2 \end{pmatrix}$$

Note that the maximum size of the \mathbf{H}_i matrix is $T-2$. The origins of the initial weighting matrix are the expected error covariances. Notice that on the diagonals,

$$E(v_{it}v_{it}) = E(\epsilon_{it}^2 - 2\epsilon_{it}\epsilon_{i(t-1)} + \epsilon_{i(t-1)}^2) = 2\sigma_\epsilon^2$$

and off diagonals,

$$E(v_{it}v_{i(t-1)}) = E(\epsilon_{it}\epsilon_{i(t-1)} - \epsilon_{it}\epsilon_{i(t-2)} - \epsilon_{i(t-1)}\epsilon_{i(t-1)} + \epsilon_{i(t-1)}\epsilon_{i(t-2)}) = -\sigma_\epsilon^2$$

If you let the vector of lagged differences (in the series y_{it}) be denoted as Δy_{i-} and the dependent variable as Δy_i , then the optimal GMM estimator is

$$\phi = \left[\left(\sum_i \Delta y_{i-}' \mathbf{Z}_i \right) A_N \left(\sum_i \mathbf{Z}_i' \Delta y_{i-} \right) \right]^{-1} \left(\sum_i \Delta y_{i-}' \mathbf{Z}_i \right) A_N \left(\sum_i \mathbf{Z}_i' \Delta y_i \right)$$

Using the estimate, $\hat{\phi}$, you can obtain estimates of the errors, $\hat{\epsilon}$, or the differences, \hat{v} . From the errors, the variance is calculated as,

$$\sigma^2 = \frac{\hat{\epsilon}'\hat{\epsilon}}{M-1}$$

where $M = \sum_{i=1}^N T_i$ is the total number of observations.

Furthermore, you can calculate the variance of the parameter as,

$$\sigma^2 \left[\left(\sum_i \Delta y_{i-}' \mathbf{Z}_i \right) A_N \left(\sum_i \mathbf{Z}_i' \Delta y_{i-} \right) \right]^{-1}$$

Alternatively, you can view the initial estimate of the ϕ as a first step. That is, by using $\hat{\phi}$, you can improve the estimate of the weight matrix, A_N .

Instead of imposing the structure of the weighting, you form the \mathbf{H}_i matrix through the following:

$$\mathbf{H}_i = \hat{v}_i \hat{v}_i'$$

You then complete the calculation as previously shown. The PROC PANEL option TWOSTEP specifies this estimation.

The case of multiple right-hand-side variables illustrates more clearly the power of Arellano and Bond (1991) and Arellano and Bover (1995).

Considering the general case you have:

$$y_{it} = \sum_{l=1}^{maxlag} \phi_l y_{i(t-l)} + \mathbf{X}_i + \gamma_i + \alpha_t + \epsilon_{it}$$

It is clear that lags of the dependent variable are both not exogenous and correlated to the fixed effects. However, the independent variables can fall into one of several categories. An independent variable can be correlated and exogenous, uncorrelated and exogenous, correlated and predetermined, and uncorrelated and predetermined. The category in which an independent variable is found influences when or whether it becomes a suitable instrument. Note, however, that neither PROC PANEL nor Arellano and Bond require that a regressor be an instrument or that an instrument be a regressor.

First, consider the question of exogenous or endogenous. An exogenous variable is not correlated with the error term in the model at all. Therefore, all observations (on the exogenous variable) become valid instruments at all time periods. If the model has only one instrument and it happens to be exogenous, then the optimal instrument matrix looks like,

$$\mathbf{Z}_i = \begin{pmatrix} x_{i1} \cdots x_{iT} & 0 & 0 & 0 & 0 \\ 0 & x_{i1} \cdots x_{iT} & 0 & 0 & 0 \\ 0 & 0 & x_{i1} \cdots x_{iTS} & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & x_{i1} \cdots x_{iTS} \end{pmatrix}$$

The situation for the predetermined variables becomes a little more difficult. A predetermined variable is one whose future realizations can be correlated to current shocks in the dependent variable. With such an understanding, it is admissible to allow all current and lagged realizations as instruments. In other words you have,

$$\mathbf{Z}_i = \begin{pmatrix} x_{i1} & 0 & 0 & 0 & 0 \\ 0 & x_{i1}x_{i2} & 0 & 0 & 0 \\ 0 & 0 & x_{i1} \cdots x_{i3} & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & x_{i1} \cdots x_{i(TS-2)} \end{pmatrix}$$

When the data contain a mix of endogenous, exogenous, and predetermined variables, the instrument matrix is formed by combining the three. The third observation would have one observation on the dependent variable as an instrument, three observations on the predetermined variables as instruments, and all observations on the exogenous variables. There is yet another set of moment restrictions that can be employed. An uncorrelated variable means that the variable's level is not affected by the individual specific effect. You write the general model presented above as:

$$y_{it} = \sum_{l=1}^{maxlag} \phi_l y_{i(t-l)} + \sum_{k=1}^K \beta_k x_{itk} + \alpha_t + \mu_{it}$$

where $\mu_{it} = \gamma_i + \epsilon_{it}$.

Since the variables are uncorrelated with γ and uncorrelated with the error, you can perform a system estimation with the difference and level equations. That is, the uncorrelated variables imply moment

restrictions on the level equation. If you denote the new instrument matrix with the full complement of instruments available by a $*$ and both x^p and x^e are uncorrelated, then you have:

$$\mathbf{Z}_i^* = \begin{pmatrix} \mathbf{Z}_i & 0 & 0 & 0 & 0 \\ 0 & x_{i1}^p & x_{i1}^e & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \cdots & x_{iTS}^p & x_{iTS}^e \end{pmatrix}$$

The formation of the initial weighting matrix becomes somewhat problematic. If you denote the new weighting matrix with a $*$, then you can write the following:

$$\mathbf{A}_N^* = \left(\frac{1}{N} \sum_i \mathbf{Z}_i^{*'} \mathbf{H}_i^* \mathbf{Z}_i^* \right)^{-1}$$

where

$$\mathbf{H}_i^* = \begin{pmatrix} \mathbf{H}_i & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 1 \end{pmatrix}$$

To finish, you write out the two equations (or two stages) that are estimated.

$$\Delta y_{it} = \boldsymbol{\beta}^* \Delta \mathbf{S}_i + \alpha_t - \alpha_{t-1} + v_{it} \qquad y_{it} = \boldsymbol{\beta}^* \mathbf{S}_i + \gamma_i + \alpha_t + \epsilon_{it}$$

where \mathbf{S}_i is the matrix of all explanatory variables, lagged endogenous, exogenous, and predetermined.

Let \mathbf{y}_{it}^* be given by

$$\mathbf{y}_{it}^* = \begin{pmatrix} \Delta y_{it} \\ y_{it} \end{pmatrix} \quad \boldsymbol{\beta}^* = (\boldsymbol{\phi} \quad \boldsymbol{\beta}) \quad \mathbf{S}_i^* = \begin{pmatrix} \Delta \mathbf{S}_i \\ \mathbf{S}_i \end{pmatrix}$$

Using the information above,

$$\boldsymbol{\beta}^* = \left[\left(\sum_i \mathbf{S}_i^{*'} \mathbf{Z}_i^* \right) \mathbf{A}_N^* \left(\sum_i \mathbf{Z}_i^{*'} \mathbf{S}_i \right) \right]^{-1} \left(\sum_i \mathbf{S}_i^{*'} \mathbf{Z}_i^* \right) \mathbf{A}_N^* \left(\sum_i \mathbf{Z}_i^{*'} \mathbf{y}_i^* \right)$$

If the TWOSTEP or ITGMM option is not requested, estimation terminates here. If it terminates, you can obtain the following information.

Variance of the error term comes from the second stage equation—that is,

$$\sigma^2 = \frac{\hat{\boldsymbol{\epsilon}}' \hat{\boldsymbol{\epsilon}}}{M - p}$$

where p is the number of regressors.

The variance covariance matrix can be obtained from

$$\left[\left(\sum_i \mathbf{S}_i^{*'} \mathbf{Z}_i^* \right) A_N^* \left(\sum_i \mathbf{Z}_i^{*'} \mathbf{S}_i^* \right) \right]^{-1} \sigma^2$$

Alternatively, a robust estimate of the variance covariance matrix can be obtained by specifying the ROBUST option. Without further reestimation of the model, the \mathbf{H}_i^* matrix is recalculated as follows:

$$\mathbf{H}_{i,2}^* = \begin{pmatrix} \mathbf{v}\mathbf{v}' & 0 \\ 0 & \boldsymbol{\epsilon}\boldsymbol{\epsilon}' \end{pmatrix}$$

And the weighting matrix becomes

$$A_{N,2}^* = \left(\frac{1}{N} \sum_i \mathbf{Z}_i^{*'} \mathbf{H}_{i,2}^* \mathbf{Z}_i^* \right)^{-1}$$

Using the information above, you construct the robust variance covariance matrix from the following:

Let \mathbf{G} denote a temporary matrix.

$$\mathbf{G} = \left[\left(\sum_i \mathbf{S}_i^{*'} \mathbf{Z}_i^* \right) A_N^* \left(\sum_i \mathbf{Z}_i^{*'} \mathbf{S}_i^* \right) \right]^{-1} \left(\sum_i \mathbf{S}_i^{*'} \mathbf{Z}_i^* \right) A_N^*$$

The robust variance covariance estimate of $\boldsymbol{\beta}^*$ is:

$$\mathbf{V}^{robust}(\boldsymbol{\beta}^*) = \mathbf{G} A_{N,2}^{*-1} \mathbf{G}'$$

Alternatively, the new weighting matrix can be used to form an updated estimate of the regression parameters. This results when the TWOSTEP option is requested. In short,

$$\boldsymbol{\beta}^* = \left[\left(\sum_i \mathbf{S}_i^{*'} \mathbf{Z}_i^* \right) A_{N,2}^* \left(\sum_i \mathbf{Z}_i^{*'} \mathbf{S}_i^* \right) \right]^{-1} \left(\sum_i \mathbf{S}_i^{*'} \mathbf{Z}_i^* \right) A_{N,2}^* \left(\sum_i \mathbf{Z}_i^{*'} \mathbf{S}_i^* \right)$$

The variance covariance estimate of the two step $\boldsymbol{\beta}^*$ becomes

$$V(\boldsymbol{\beta}^*) = \left[\left(\sum_i \mathbf{S}_i^{*'} \mathbf{Z}_i^* \right) A_{N,2}^* \left(\sum_i \mathbf{Z}_i^{*'} \mathbf{S}_i^* \right) \right]^{-1}$$

As a final note, it possible to iterate more than twice by specifying the ITGMM option. Such a multiple iteration should result in a more stable estimate of the variance covariance estimate. PROC PANEL allows two convergence criteria. Convergence can occur in the parameter estimates or in the weighting matrices. Iterate until

$$\max_{i,j \leq \dim(A_{N,k})} \frac{|A_{N,k+1}^*(i,j) - A_{N,k}^*(i,j)|}{|A_{N,k}^*(i,j)|} \leq \text{ATOL}$$

or

$$\max_{i \leq \dim(\beta_k^*)} \frac{|\beta_{k+1}^*(i) - \beta_k^*(i)|}{|\beta_k^*(i)|} \leq \text{BTOL}$$

where ATOL is the tolerance for convergence in the weighting matrix and BTOL is the tolerance for convergence in the parameter estimate matrix. The default convergence criteria is BTOL = 1E-8 for PROC PANEL.

Specification Testing For Dynamic Panel

Specification tests under the GMM in PROC PANEL follow Arellano and Bond (1991) very generally. The first test available is a Sargan/Hansen test of over-identification. The test for a one-step estimation is constructed as

$$\left(\sum_i \eta_i' \mathbf{Z}_i^* \right) A_N^* \left(\sum_i \mathbf{Z}_i^{*'} \eta_i \right) \sigma^2$$

where η_i is the stacked error term (of the differenced equation and level equation).

When the robust weighting matrix is used, the test statistic is computed as

$$\left(\sum_i \eta_i' \mathbf{Z}_i^* \right) A_{N,2}^* \left(\sum_i \mathbf{Z}_i^{*'} \eta_i \right)$$

This definition of the Sargan test is used for all iterated estimations. The Sargan test is distributed as a χ^2 with degrees of freedom equal to the number of moment conditions minus the number of parameters.

In addition to the Sargan test, PROC PANEL tests for autocorrelation in the residuals. These tests are distributed as standard normal. PROC PANEL tests the hypothesis that the autocorrelation of the l th lag is significant.

Define ω_l as the lag of the differenced error, with zero padding for the missing values generated. Symbolically,

$$\omega_l = \begin{pmatrix} 0 \\ \vdots \\ 0 \\ v_1 \\ \vdots \\ v_{TS-2-l} \end{pmatrix}$$

You define the constant k_0 as

$$k_0(l) = \sum_i \omega_{l,i}' v_i$$

You next define the constant k_1 as

$$k_1(l) = \sum_i \omega_{l,i}' \mathbf{H}_i \omega_{l,i}$$

Note that the choice of \mathbf{H}_i is dependent on the stage of estimation. If the estimation is first stage, then you would use the matrix with twos along the main diagonal, and minus ones along the primary subdiagonals. In a robust estimation or multi-step estimation, this matrix would be formed from the outer product of the residuals (from the previous step).

Define the constant k_2 as

$$k_2(l) = -2 \left(\sum_i \omega'_{l,i} \Delta \mathbf{S}_i \right) \mathbf{G} \left(\sum_i \Delta \mathbf{S}'_i \mathbf{Z}_i \right) A_{N,k} \left(\sum_i \mathbf{Z}'_i \mathbf{H}_i \omega_{l,i} \right)$$

The matrix \mathbf{G} is defined as

$$\mathbf{G} = \left[\left(\sum_i \Delta \mathbf{S}'_i \mathbf{Z}_i \right) A_{N,k}^* \left(\sum_i \mathbf{Z}'_i \Delta \mathbf{S}_i \right) \right]^{-1}$$

The constant k_3 is defined as

$$k_3(l) = \left(\sum_i \omega'_{l,i} \Delta \mathbf{S}_i \right) V(\boldsymbol{\beta}^*) \left(\sum_i \Delta \mathbf{S}'_i \omega_{l,i} \right)$$

Using the four quantities, the test for autoregressive structure in the differenced residual is

$$m(l) = \frac{k_0(l)}{\sqrt{k_1(l) + k_2(l) + k_3(l)}}$$

The m statistic is distributed as a normal random variable with mean zero and standard deviation of one.

Instrument Choice

Arellano and Bond's technique is a very useful method for dealing with any autoregressive characteristics in the data. However, there is one caveat to consider. Too many instruments bias the estimator to the within estimate. Furthermore, many instruments make this technique not scalable. The weighting matrix becomes very large, so every operation that involves it becomes more computationally intensive. The PANEL procedure enables you to specify a bandwidth for instrument selection. For example, specifying MAXBAND=10 means that at most there will be ten time observations for each variable that enters as an instrument. The default is to follow the Arellano-Bond methodology.

In specifying a maximum bandwidth, you can also specify the selection of the time observations. There are three possibilities: leading, trailing (default), and centered. The exact consequence of choosing any of those possibilities depends on the variable type (correlated, exogenous, or predetermined) and the time period of the current observation.

If the MAXBAND option is specified, then the following is true under any selection criterion (let t be the time subscript for the current observation). The first observation for the endogenous variable (as instrument) is $\max(t - \text{MAXBAND}, 1)$ and the last instrument is $t - 2$. The first observation for a predetermined variable is $\max(t - \text{MAXBAND}, 1)$ and the last is $t - 1$. The first and last observation for an exogenous variable is given in the following list:

- *Trailing*: If $t < \text{MAXBAND}$, then the first instrument is for the first time period and the last observation is MAXBAND . Otherwise, if $t \geq \text{MAXBAND}$, then the first observation is $t - \text{MAXBAND} + 1$ and the last instrument to enter is t .
- *Centered*: If $t \leq \frac{\text{MAXBAND}}{2}$, then the first observation is the first time period and the last observation is MAXBAND . If $t > T - \frac{\text{MAXBAND}}{2}$, then the first instrument included is $T - \text{MAXBAND} + 1$ and the last observation is T . If $\frac{\text{MAXBAND}}{2} < t \leq T - \frac{\text{MAXBAND}}{2}$, then the first included instrument is $t - \frac{\text{MAXBAND}}{2} + 1$ and the last observation is $t + \frac{\text{MAXBAND}}{2}$. If the MAXBAND value is an odd number, the procedure decrements by one.
- *Leading* : If $t > T - \text{MAXBAND}$, then the first instrument corresponds to time period $T - \text{MAXBAND} + 1$ and the last observation is T . Otherwise, if $t \leq T - \text{MAXBAND}$, then the first observation is t and the last observation is $t + \text{MAXBAND} + 1$.

The PANEL procedure enables you to include dummy variables to deal with the presence of time effects that are not captured by including the lagged dependent variable. The dummy variables directly affect the level equations. However, this implies that the difference of the dummy variable for time period t and $t - 1$ enters the difference equation. The first usable observation occurs at $t = 3$. If the level equation is not used in the estimation, then there is no way to identify the dummy variables. Selecting the TIME option gives the same result as that which would be obtained by creating dummy variables in the data set and using those in the regression.

The PANEL procedure gives you several options when it comes to missing values and unbalanced panel. By default, any time period for which there are missing values is skipped. The corresponding rows and columns of \mathbf{H} matrices are zeroed, and the calculation is continued. Alternatively, you can elect to replace missing values and missing observations with zeros (ZERO), the overall mean of the series (OAM), the cross-sectional mean (CSM), or the time series mean (TSM).

Linear Hypothesis Testing

For a linear hypothesis of the form $\mathbf{R}\beta = \mathbf{r}$ where \mathbf{R} is $J \times K$ and \mathbf{r} is $J \times 1$, the F -statistic with $J, M - K$ degrees of freedom is computed as

$$(\mathbf{R}\hat{\beta} - \mathbf{r})' [\mathbf{R}\hat{\mathbf{V}}\mathbf{R}']^{-1} (\mathbf{R}\hat{\beta} - \mathbf{r})$$

However, it is also possible to write the F statistic as

$$F = \frac{(\hat{\mathbf{u}}_*' \hat{\mathbf{u}}_* - \hat{\mathbf{u}}' \hat{\mathbf{u}}) / J}{\hat{\mathbf{u}}' \hat{\mathbf{u}} / (M - K)}$$

where

- $\hat{\mathbf{u}}_*$ is the residual vector from the restricted regression
- $\hat{\mathbf{u}}$ is the residual vector from the unrestricted regression

- J is the number of restrictions
- $(M - K)$ are the degrees of freedom, M is the number of observations, and K is the number of parameters in the model

The Wald, likelihood ratio (LR) and Lagrange multiplier (LM) tests are all related to the F test. You use this relationship of the F test to the likelihood ratio and Lagrange multiplier tests. The Wald test is calculated from its definition.

The Wald test statistic is:

$$W = (\mathbf{R}\beta - \mathbf{r})' [\mathbf{R}\hat{\mathbf{V}}\mathbf{R}']^{-1} (\mathbf{R}\beta - \mathbf{r})$$

The advantage of calculating Wald in this manner is that it enables you to substitute a heteroscedasticity-corrected covariance matrix for the matrix \mathbf{V} . PROC PANEL makes such a substitution if you request the HCCME option in the MODEL statement.

The likelihood ratio is:

$$LR = M \ln \left[1 + \frac{1}{M - K} JF \right]$$

The Lagrange multiplier test statistic is:

$$LM = M \left[\frac{JF}{M - K + JF} \right]$$

where JF represents the number of restrictions multiplied by the result of the F test.

Note that only the Wald is changed when the HCCME option is selected. The LR and LM tests are unchanged.

The distribution of these test statistics is the χ^2 with degrees of freedom equal to the number of restrictions imposed (J). The three tests are asymptotically equivalent, but they have differing small sample properties. Greene (2000, p. 392) and Davidson and MacKinnon (1993, pg. 456-458) discuss the small sample properties of these statistics.

Heteroscedasticity-Corrected Covariance Matrices

The MODEL statement HCCME= option is used to select the type of heteroscedasticity-consistent covariance matrix. In the presence of heteroscedasticity, the covariance matrix has a complicated structure which can result in inefficiencies in the OLS estimates and biased estimates of the variance covariance matrix. Consider the simple linear model (this discussion parallels the discussion in Davidson and MacKinnon, 1993, pg. 548-562):

$$\mathbf{y} = \mathbf{X}\beta + \boldsymbol{\epsilon}$$

The assumptions that make the linear regression best linear unbiased estimator (BLUE) are $E(\boldsymbol{\epsilon}) = 0$ and $E(\boldsymbol{\epsilon}\boldsymbol{\epsilon}') = \Omega$, where Ω has the simple structure $\sigma^2\mathbf{I}$. Heteroscedasticity results in a general covariance structure, so that it is not possible to simplify Ω . The result is the following:

$$\tilde{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{y} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'(\mathbf{X}\beta + \boldsymbol{\epsilon}) = \beta + (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\boldsymbol{\epsilon}$$

As long as the following is true, then you are assured that the OLS estimate is consistent and unbiased:

$$plim_{n \rightarrow \infty} \left(\frac{1}{n} \mathbf{X}' \boldsymbol{\epsilon} \right) = 0$$

If the regressors are nonrandom, then it is possible to write the variance of the estimated $\boldsymbol{\beta}$ as the following:

$$\text{Var}(\boldsymbol{\beta} - \tilde{\boldsymbol{\beta}}) = (\mathbf{X}'\mathbf{X})^{-1} \mathbf{X}' \boldsymbol{\Omega} \mathbf{X} (\mathbf{X}'\mathbf{X})^{-1}$$

The effect of structure in the variance covariance matrix can be ameliorated by using generalized least squares (GLS), provided that $\boldsymbol{\Omega}^{-1}$ can be calculated. Using $\boldsymbol{\Omega}^{-1}$, you premultiply both sides of the regression equation,

$$\boldsymbol{\Omega}^{-1} \mathbf{y} = \boldsymbol{\Omega}^{-1} \mathbf{X} \boldsymbol{\beta} + \boldsymbol{\Omega}^{-1} \boldsymbol{\epsilon}$$

The resulting GLS $\boldsymbol{\beta}$ is

$$\hat{\boldsymbol{\beta}} = (\mathbf{X}' \boldsymbol{\Omega}^{-1} \mathbf{X})^{-1} \mathbf{X}' \boldsymbol{\Omega}^{-1} \mathbf{y}$$

Using the GLS $\boldsymbol{\beta}$, you can write

$$\begin{aligned} \hat{\boldsymbol{\beta}} &= (\mathbf{X}' \boldsymbol{\Omega}^{-1} \mathbf{X})^{-1} \mathbf{X}' \boldsymbol{\Omega}^{-1} \mathbf{y} \\ &= (\mathbf{X}' \boldsymbol{\Omega}^{-1} \mathbf{X})^{-1} \mathbf{X}' (\boldsymbol{\Omega}^{-1} \mathbf{X} \boldsymbol{\beta} + \boldsymbol{\Omega}^{-1} \boldsymbol{\epsilon}) \\ &= \boldsymbol{\beta} + (\mathbf{X}' \boldsymbol{\Omega}^{-1} \mathbf{X})^{-1} \mathbf{X}' \boldsymbol{\Omega}^{-1} \boldsymbol{\epsilon} \end{aligned}$$

The resulting variance expression for the GLS estimator is

$$\begin{aligned} \text{Var}(\boldsymbol{\beta} - \hat{\boldsymbol{\beta}}) &= (\mathbf{X}' \boldsymbol{\Omega}^{-1} \mathbf{X})^{-1} \mathbf{X}' \boldsymbol{\Omega}^{-1} \boldsymbol{\epsilon} \boldsymbol{\epsilon}' \boldsymbol{\Omega}^{-1} \mathbf{X} (\mathbf{X}' \boldsymbol{\Omega}^{-1} \mathbf{X})^{-1} \\ &= (\mathbf{X}' \boldsymbol{\Omega}^{-1} \mathbf{X})^{-1} \mathbf{X}' \boldsymbol{\Omega}^{-1} \boldsymbol{\Omega} \boldsymbol{\Omega}^{-1} \mathbf{X} (\mathbf{X}' \boldsymbol{\Omega}^{-1} \mathbf{X})^{-1} \\ &= (\mathbf{X}' \boldsymbol{\Omega}^{-1} \mathbf{X})^{-1} \end{aligned}$$

The difference in variance between the OLS estimator and the GLS estimator can be written as

$$(\mathbf{X}'\mathbf{X})^{-1} \mathbf{X}' \boldsymbol{\Omega} \mathbf{X} (\mathbf{X}'\mathbf{X})^{-1} - (\mathbf{X}' \boldsymbol{\Omega}^{-1} \mathbf{X})^{-1}$$

By the Gauss Markov Theory, the difference matrix must be positive definite under most circumstances (zero if OLS and GLS are the same, when the usual classical regression assumptions are met). Thus, OLS is not efficient under a general error structure. It is crucial to realize that OLS does not produce biased results. It would suffice if you had a method for estimating a consistent covariance matrix and you used the OLS $\boldsymbol{\beta}$. Estimation of the $\boldsymbol{\Omega}$ matrix is by no means simple. The matrix is square and has M^2 elements, so unless some sort of structure is assumed, it becomes an impossible problem to solve. However, the heteroscedasticity can have quite a general structure. White (1980) shows that it is not necessary to have a consistent estimate of $\boldsymbol{\Omega}$. On the contrary, it suffices to get an estimate of the middle expression. That is, you need an estimate of:

$$\boldsymbol{\Lambda} = \mathbf{X}' \boldsymbol{\Omega} \mathbf{X}$$

This matrix, $\boldsymbol{\Lambda}$, is easier to estimate because its dimension is K . PROC PANEL provides the following classical HCCME estimators:

The matrix $\boldsymbol{\Lambda}$ is approximated by:

- *HCCME=N0*: This is the simple OLS estimator so $(\mathbf{X}'\mathbf{X})$. If you do not request the *HCCME=* option, then PROC PANEL defaults to this estimator.

- *HCCME=0*:

$$\frac{1}{M} \sum_{i=0}^M \hat{\epsilon}_i^2 \mathbf{x}_i \mathbf{x}_i'$$

The \mathbf{x}_i constitutes the *ith* row of the matrix \mathbf{X}_s .

- *HCCME=1*:

$$\frac{1}{M} \sum_{i=0}^M \left(\frac{M}{M-K} \hat{\epsilon}_i^2 \mathbf{x}_i \mathbf{x}_i' \right)$$

- *HCCME=2*:

$$\frac{1}{M} \sum_{i=0}^M \frac{\hat{\epsilon}_i^2}{1 - \hat{h}_i} \mathbf{x}_i \mathbf{x}_i'$$

The \hat{h}_i term is *ith* diagonal element of the so called hat matrix. The expression for \hat{h}_i is $\mathbf{X}_i (\mathbf{X}'\mathbf{X})^{-1} \mathbf{X}_i'$. The hat matrix attempts to adjust the estimates for the presence of influence or leverage points.

- *HCCME=3*:

$$\frac{1}{n} \sum_{i=0}^M \frac{\hat{\epsilon}_i^2}{(1 - \hat{h}_i)^2} \mathbf{x}_i \mathbf{x}_i'$$

- *HCCME=4*: This is the Arellano (1987) version of the White (1980) HCCME for panel. PROC PANEL includes an option for the calculation of the Arellano (1987) version of the White HCCME in the panel setting. Arellano's insight is that in a panel there are *N* covariance matrices, each corresponding to a cross section. Forming the White (1980) HCCME for each panel, you need to take only the average of those *N* estimators that yield Arellano. The details of the estimation follow. First, you arrange the data such that the first cross section occupies the first *T_i* observations. You treat the panels as separate regressions with the form:

$$\mathbf{y}_i = \alpha_i \mathbf{i} + \mathbf{X}_{is} \tilde{\boldsymbol{\beta}} + \boldsymbol{\epsilon}_i$$

The parameter estimates $\tilde{\boldsymbol{\beta}}$ and α_i are the result of LSDV or within estimator. \mathbf{i} is a vector ones of length *T_i*. The estimate of the *i*th cross section's $\mathbf{X}'\boldsymbol{\Omega}\mathbf{X}$ matrix (where the *s* subscript indicates that no constant column has been suppressed to avoid confusion) is $\mathbf{X}_i' \boldsymbol{\Omega} \mathbf{X}_i$. The estimate for the whole sample is:

$$\mathbf{X}_s' \boldsymbol{\Omega} \mathbf{X}_s = \sum_{i=1}^N \mathbf{X}_i' \boldsymbol{\Omega} \mathbf{X}_i$$

The Arellano standard error is in fact a White-Newey-West estimator with constant and equal weight on each component. It should be noted that, in the between estimators, selecting *HCCME = 4* returns the *HCCME = 0* result since there is no 'other' variable to group by.

In their discussion, Davidson and MacKinnon (1993, pg. 554) argue that HCCME=1 should always be preferred to HCCME=0. While generally HCCME=3 is preferred to 2 and 2 is preferred to 1, the calculation of HCCME=1 is as simple as the calculation of HCCME=0. Therefore, it is clear that HCCME=1 is preferred when the calculation of the hat matrix is too tedious.

All HCCME estimators have well defined asymptotic properties. The small sample properties are not well known, and care must be exercised when sample sizes are small.

The HCCME estimator of $\text{Var}(\boldsymbol{\beta})$ is used to drive the covariance matrices for the fixed effects and the Lagrange multiplier standard errors. Robust estimates of the variance covariance matrix for $\boldsymbol{\beta}$ imply robust variance covariance matrices for all other parameters.

R-Square

The conventional R-square measure is inappropriate for all models that the PANEL procedure estimates by using GLS since a number outside the [0,1] range might be produced. Hence, a generalization of the R-square measure is reported. The following goodness-of-fit measure (Buse 1973) is reported:

$$R^2 = 1 - \frac{\hat{\mathbf{u}}' \hat{\mathbf{V}}^{-1} \hat{\mathbf{u}}}{\mathbf{y}' \mathbf{D}' \hat{\mathbf{V}}^{-1} \mathbf{D} \mathbf{y}}$$

where $\hat{\mathbf{u}}$ are the residuals of the transformed model, $\hat{\mathbf{u}} = \mathbf{y} - \mathbf{X}(\mathbf{X}' \hat{\mathbf{V}}^{-1} \mathbf{X})^{-1} \mathbf{X}' \hat{\mathbf{V}}^{-1} \mathbf{y}$,

and $\mathbf{D} = \mathbf{I}_M - \mathbf{j}_M \mathbf{j}_M' \left(\frac{\hat{\mathbf{V}}^{-1}}{\mathbf{j}_M' \hat{\mathbf{V}}^{-1} \mathbf{j}_M} \right)$.

This is a measure of the proportion of the transformed sum of squares of the dependent variable that is attributable to the influence of the independent variables.

If there is no intercept in the model, the corresponding measure (Theil 1961) is

$$R^2 = 1 - \frac{\hat{\mathbf{u}}' \hat{\mathbf{V}}^{-1} \hat{\mathbf{u}}}{\mathbf{y}' \hat{\mathbf{V}}^{-1} \mathbf{y}}$$

However, the fixed-effects models are somewhat different. In the case of a fixed-effects model, the choice of including or excluding an intercept becomes merely a choice of classification. Suppressing the intercept in the FIXONE or FIXONETIME case merely changes the name of the intercept to a fixed effect. It makes no sense to redefine the R-square measure since nothing material changes in the model. Similarly, for the FIXTWO model there is no reason to change R-square. In the case of the FIXONE, FIXONETIME, and FIXTWO models, the R-square is defined as the Theil (1961) R-square (detailed above). This makes intuitive sense since you are regressing a transformed (demeaned) series on transformed regressors, excluding a constant. In other words, you are looking at one minus the sum of squared errors divided by the sum of squares of the (transformed) dependent variable.

In the case of OLS estimation, both of the R-square formulas given here reduce to the usual R-square formula.

Specification Tests

The PANEL procedure outputs the results of one specification test for fixed effects and two specification tests for random effects.

For fixed effects, let β_f be the n dimensional vector of fixed-effects parameters. The specification test reported is the conventional F statistic for the hypothesis $\beta_f = \mathbf{0}$. The F statistic with $n, M - K$ degrees of freedom is computed as

$$\hat{\beta}_f \hat{\mathbf{S}}_f^{-1} \hat{\beta}_f / n$$

where $\hat{\mathbf{S}}_f$ is the estimated covariance matrix of the fixed-effects parameters.

Hausman's (1978) specification test or m statistic can be used to test hypotheses in terms of bias or inconsistency of an estimator. This test was also proposed by Wu (1973) and further extended in Hausman and Taylor (1982). Hausman's m statistic is as follows.

Consider two estimators, $\hat{\beta}_a$ and $\hat{\beta}_b$, which under the null hypothesis are both consistent, but only $\hat{\beta}_a$ is asymptotically efficient. Under the alternative hypothesis, only $\hat{\beta}_b$ is consistent. The m statistic is

$$m = (\hat{\beta}_b - \hat{\beta}_a)' (\hat{\mathbf{S}}_b - \hat{\mathbf{S}}_a)^{-1} (\hat{\beta}_b - \hat{\beta}_a)$$

where $\hat{\mathbf{S}}_b$ and $\hat{\mathbf{S}}_a$ are consistent estimates of the asymptotic covariance matrices of $\hat{\beta}_b$ and $\hat{\beta}_a$. Then m is distributed χ^2 with k degrees of freedom, where k is the dimension of $\hat{\beta}_a$ and $\hat{\beta}_b$.

In the random-effects specification, the null hypothesis of no correlation between effects and regressors implies that the OLS estimates of the slope parameters are consistent and inefficient but the GLS estimates of the slope parameters are consistent and efficient. This facilitates a Hausman specification test. The reported χ^2 statistic has degrees of freedom equal to the number of slope parameters. If the null hypothesis holds, the random-effects specification should be used.

Breusch and Pagan (1980) lay out a Lagrange multiplier test for random effects based on the simple OLS (pooled) estimator. If \hat{u}_{it} is the it th residual from the OLS regression, then the Breusch-Pagan (BP) test for one-way random effects is

$$BP = \frac{NT}{2(T-1)} \left[\frac{\sum_{i=1}^N \left[\sum_{t=1}^T \hat{u}_{it} \right]^2}{\sum_{i=1}^N \sum_{t=1}^T \hat{u}_{it}^2} - 1 \right]^2$$

The BP test generalizes to the case of a two-way random-effects model (Greene 2000, page 589). Specifically,

$$BP2 = \frac{NT}{2(T-1)} \left[\frac{\sum_{i=1}^n \left[\sum_{t=1}^T \hat{u}_{it} \right]^2}{\sum_{i=1}^n \sum_{t=1}^T \hat{u}_{it}^2} - 1 \right]^2 + \frac{NT}{2(N-1)} \left[\frac{\sum_{t=1}^T \left[\sum_{i=1}^N \hat{u}_{it} \right]^2}{\sum_{i=1}^N \sum_{t=1}^T \hat{u}_{it}^2} - 1 \right]^2$$

is distributed as a χ^2 statistic with two degrees of freedom. Since the BP2 test generalizes (nests the BP test) the test for random effects, the absence of random effects (nonrejection of the null of no random effects) in the BP2 is a fairly clear indication that there will probably not be any one-way effects either. In both cases (BP and BP2), the residuals are obtained from a pooled regression. There is very little extra cost in selecting both the BP and BP2 test. Notice that in the case of just groupwise heteroscedasticity, the BP2 test approaches BP. In the case of time based heteroscedasticity, the BP2 test reduces to a BP test of time effects. In the case of unbalanced panels, neither the BP nor BP2 statistics are valid.

Finally, you should be aware that the BP option generates different results depending on whether the estimation is `FIXONE` or `FIXONETIME`. Specifically, under the `FIXONE` estimation technique, the BP tests for cross-sectional random effects. Under the `FIXONETIME` estimation, the BP tests for time random effects.

While the Hausman statistic is automatically generated, you request Breusch-Pagan via the BP or BP2 option (see Baltagi 1995 for details).

Troubleshooting

Some guidelines need to be followed when you use PROC PANEL for analysis. For each cross section, PROC PANEL requires at least two time series observations with nonmissing values for all model variables. There should be at least two cross sections for each time point in the data. If these two conditions are not met, then an error message is printed in the log stating that there is only one cross section or time series observation and further computations will be terminated. You have to give adequate data for an estimation method to produce results, and you should check the log for any data related errors.

If the number of cross sections is greater than the number of time series observations per cross section, PROC PANEL while using PARKS method produces an error message stating that the phi matrix is singular. This is analogous to seemingly unrelated regression with fewer observations than equations in the model. To avoid the problem, reduce the number of cross sections.

Your data set could have multiple observations for each time ID within a particular cross section. However, PROC PANEL is applicable only in cases where you have only a single observation for each time ID within each cross section. In such a case, after you have sorted the data, an error warning specifying that the data has not been sorted in ascending sequence with respect to time series ID appears in the log.

The cause of the error is due to multiple observations for each time ID for a given cross section. PROC PANEL allows only one observation for each time ID within each cross section.

The following data set shown in [Figure 19.2](#) illustrates the preceding instance with the correct representation.

Figure 19.2 Single Observation for Each Time Series

Obs	firm	year	production	cost
1	1	1955	5.36598	1.14867
2	1	1960	6.03787	1.45185
3	1	1965	6.37673	1.52257
4	1	1970	6.93245	1.76627
5	2	1955	6.54535	1.35041
6	2	1960	6.69827	1.71109
7	2	1965	7.40245	2.09519
8	2	1970	7.82644	2.39480

In this case, you can observe that there are no multiple observations with respect to a given time series ID within a cross section. This is the correct representation of a data set where PROC PANEL is applicable.

If for state ID 1 you have two observations for the year=1955, then PROC PANEL produces the following error message:

“The data set is not sorted in ascending sequence with respect to time series ID. The current time period has year=1955 and the previous time period has year=1955 in cross section firm=1.”

A data set similar to the previous example with multiple observations for the YEAR=1955 is shown in [Figure 19.3](#); this data set results in an error message due to multiple observations while using PROC PANEL.

Figure 19.3 Multiple Observations for Each Time Series

Obs	firm	year	production	cost
1	1	1955	5.36598	1.14867
2	1	1955	6.37673	1.52257
3	1	1960	6.03787	1.45185
4	1	1970	6.93245	1.76627
5	2	1955	6.54535	1.35041
6	2	1960	6.69827	1.71109
7	2	1965	7.40245	2.09519
8	2	1970	7.82644	2.39480

In order to use PROC PANEL, you need to aggregate the data so that you have unique time ID values within each cross section. One possible way to do this is to run a PROC MEANS on the input data set and compute the mean of all the variables by FIRM and YEAR, and then use the output data set.

ODS Graphics

This section describes the use of ODS for creating graphics with the PANEL procedure. Both the graphical results and the syntax for specifying them are subject to change in a future release.

To request these graphs, you must specify the ODS GRAPHICS statement. The table below lists the graph names, the plot descriptions, and the options used.

Table 19.2 ODS Graphics Produced by PROC PANEL

ODS Graph Name	Plot Description	Plots=Option
ResidualPlot	Plot of the residuals	RESIDUAL, RESID
FitPlot	Predicted versus actual plot	FITPLOT
QQPlot	Plot of the quantiles of the residuals	QQ
ResidSurfacePlot	Surface plot of the residuals	RESIDSURFACE
PredSurfacePlot	Surface plot of the predicted values	PREDSURFACE
ActSurfacePlot	Surface plot of the actual values	ACTSURFACE
ResidStackPlot	Stack plot of the residuals	RESIDSTACK, RESSTACK
ResidHistogram	Plot of the histogram of residuals	RESIDUALHISTOGRAM, RESIDHISTOGRAM

The OUTPUT OUT= Data Set

PROC PANEL writes the initial data of the estimated model, predicted values, and residuals to an output data set when the OUTPUT OUT= statement is specified. The OUT= data set contains the following variables:

<code>_MODELL_</code>	is a character variable that contains the label for the MODEL statement if a label is specified.
<code>_METHOD_</code>	is a character variable that identifies the estimation method.
<code>_MODLNO_</code>	is the number of the model estimated.
<code>_ACTUAL_</code>	contains the value of the dependent variable.
<code>_WEIGHT_</code>	contains the weighing variable.
<code>_CSID_</code>	is the value of the cross section ID.
<code>_TSID_</code>	is the value of the time period in the dynamic model.
regressors	are the values of regressor variables specified in the MODEL statement.
<i>name</i>	if PRED= <i>name1</i> and/or RESIDUAL= <i>name2</i> options are specified, then <i>name1</i> and <i>name2</i> are the columns of predicted values of dependent variable and residuals of the regression, respectively.

The OUTEST= Data Set

PROC PANEL writes the parameter estimates to an output data set when the OUTEST= option is specified. The OUTEST= data set contains the following variables:

<code>_MODEL_</code>	is a character variable that contains the label for the MODEL statement if a label is specified.
<code>_METHOD_</code>	is a character variable that identifies the estimation method.
<code>_TYPE_</code>	is a character variable that identifies the type of observation. Values of the <code>_TYPE_</code> variable are CORRB, COVB, CSPARMS, and PARMS; the CORRB observation contains correlations of the parameter estimates; the COVB observation contains covariances of the parameter estimates; the CSPARMS observation contains cross-sectional parameter estimates; and the PARMS observation contains parameter estimates.
<code>_NAME_</code>	is a character variable that contains the name of a regressor variable for COVB and CORRB observations and is left blank for other observations. The <code>_NAME_</code> variable is used in conjunction with the <code>_TYPE_</code> values COVB and CORRB to identify rows of the correlation or covariance matrix.
<code>_DEPVAR_</code>	is a character variable that contains the name of the response variable.
<code>_MSE_</code>	is the mean square error of the transformed model.
<code>_CSID_</code>	is the value of the cross section ID for CSPARMS observations. The <code>_CSID_</code> variable is used with the <code>_TYPE_</code> value CSPARMS to identify the cross section for the first-order autoregressive parameter estimate contained in the observation. The <code>_CSID_</code> variable is missing for observations with other <code>_TYPE_</code> values. (Currently, only the <code>_A_1</code> variable contains values for CSPARMS observations.)
<code>_VARCS_</code>	is the variance component estimate due to cross sections. The <code>_VARCS_</code> variable is included in the OUTEST= data set when either the FULLER or DASILVA option is specified.
<code>_VARTS_</code>	is the variance component estimate due to time series. The <code>_VARTS_</code> variable is included in the OUTEST= data set when either the FULLER or DASILVA option is specified.
<code>_VARERR_</code>	is the variance component estimate due to error. The <code>_VARERR_</code> variable is included in the OUTEST= data set when the FULLER option is specified.
<code>_A_1</code>	is the first-order autoregressive parameter estimate. The <code>_A_1</code> variable is included in the OUTEST= data set when the PARKS option is specified. The values of <code>_A_1</code> are cross-sectional parameters, meaning that they are estimated for each cross section separately. The <code>_A_1</code> variable has a value only for <code>_TYPE_=CSPARMS</code> observations. The cross section to which the estimate belongs is indicated by the <code>_CSID_</code> variable.
Intercept	is the intercept parameter estimate. (Intercept is missing for models when the NOINT option is specified.)
regressors	are the regressor variables specified in the MODEL statement. The regressor variables in the OUTEST= data set contain the corresponding parameter estimates for the model identified by <code>_MODEL_</code> for <code>_TYPE_=PARMS</code> observations, and the corresponding covariance or correlation matrix elements for <code>_TYPE_=COVB</code> and <code>_TYPE_=CORRB</code> observations. The response variable contains the value-1 for the <code>_TYPE_=PARMS</code> observation for its model.

The OUTTRANS= Data Set

PROC PANEL writes the transformed series to an output data set. That is, if the user selects FIXONE, FIXONETIME, or RANONE and supplies the OUTTRANS = option, the transformed dependent variable and independent variables are written out to a SAS data set; other variables in the input data set are copied unchanged.

Say that your data set contains variables y , x_1 , x_2 , x_3 , and z_2 . The following statements result in a SAS data set:

```
proc panel data=datain outtrans=dataout;
  id cs ts;
  model y = x1 x2 x3 / fixone;
run;
```

First, z_2 is copied over. Then $_Int$, x_1 , x_2 , y , and x_3 , are replaced with their mean deviates (from cross sections). Furthermore, two new variables are created.

$_MODELL_$ is the model's label (if it exists).
 $_METHOD_$ is the model's transformation type. In the FIXONE case, this is $_FIXONE_$ or $_FIXONETIME_$. If the model RANONE model is selected, the $_METHOD_$ variable is either $_Ran1FB_$, $_Ran1WK_$, $_Ran1WH_$, or $_Ran1NL_$, depending on the variance component estimators chosen.

Printed Output

For each MODEL statement, the printed output from PROC PANEL includes the following:

- a model description, which gives the estimation method used, the model statement label if specified, the number of cross sections and the number of observations in each cross section, and the order of moving average error process for the DASILVA option. For fixed-effects model analysis, an F test for the absence of fixed effects is produced, and for random-effects model analysis, a Hausman test is used for the appropriateness of the random-effects specification.
- the estimates of the underlying error structure parameters
- the regression parameter estimates and analysis. For each regressor, this includes the name of the regressor, the degrees of freedom, the parameter estimate, the standard error of the estimate, a t statistic for testing whether the estimate is significantly different from 0, and the significance probability of the t statistic.

Optionally, PROC PANEL prints the following:

- the covariance and correlation of the resulting regression parameter estimates for each model and assumed error structure

- the $\hat{\Phi}$ matrix that is the estimated contemporaneous covariance matrix for the PARKS option

ODS Table Names

PROC PANEL assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 19.3.

Table 19.3 ODS Tables Produced in PROC PANEL

ODS Table Name	Description	Option
ODS Tables Created by the MODEL Statement		
ModelDescription	Model description	Default
FitStatistics	Fit statistics	Default
FixedEffectsTest	<i>F</i> test for no fixed effects	FIXONE, FIXTWO, FIXONETIME

Example: PANEL Procedure

Example 19.1: Analyzing Demand for Liquid Assets

In this example, the demand equations for liquid assets are estimated. The demand function for the demand deposits is estimated under three error structures while demand equations for time deposits and savings and loan (S&L) association shares are calculated using the Parks method. The data for seven states (CA, DC, FL, IL, NY, TX, and WA) are selected out of 49 states. See Feige (1964) for data description. All variables were transformed via natural logarithm. The data set A is shown below.

```
data a;
  length state $ 2;
  input state $ year d t s y rd rt rs;
  label d = 'Per Capita Demand Deposits'
        t = 'Per Capita Time Deposits'
        s = 'Per Capita S & L Association Shares'
        y = 'Permanent Per Capita Personal Income'
        rd = 'Service Charge on Demand Deposits'
        rt = 'Interest on Time Deposits'
        rs = 'Interest on S & L Association Shares';
datalines;
CA  1949  6.2785  6.1924  4.4998  7.2056 -1.0700  0.1080  1.0664
CA  1950  6.4019  6.2106  4.6821  7.2889 -1.0106  0.1501  1.0767
CA  1951  6.5058  6.2729  4.8598  7.3827 -1.0024  0.4008  1.1291
CA  1952  6.4785  6.2729  5.0039  7.4000 -0.9970  0.4492  1.1227
CA  1953  6.4118  6.2538  5.1761  7.4200 -0.8916  0.4662  1.2110

... more lines ...
```

As shown in the following statements, the SORT procedure is used to sort the data into the required time series cross-sectional format; then PROC PANEL analyzes the data.

```
proc sort data=a;
  by state year;
run;

proc panel data=a;
  model d = y rd rt rs / fuller parks dasilva m=7;
  model t = y rd rt rs / parks;
  model s = y rd rt rs / parks;
  id state year;
run;
```

The income elasticities for liquid assets are greater than 1 except for the demand deposit income elasticity (0.692757) estimated by the Da Silva method. In [Output 19.1.1](#), [Output 19.1.2](#), and [Output 19.1.3](#), the coefficient estimates (−0.29094, −0.43591, and −0.27736) of demand deposits

(RD) imply that demand deposits increase significantly as the service charge is reduced. The price elasticities (0.227152 and 0.408066) for time deposits (RT) and S&L association shares (RS) have the expected sign. Thus an increase in the interest rate on time deposits or S&L shares will increase the demand for the corresponding liquid asset. Demand deposits and S&L shares appear to be substitutes (see [Output 19.1.2](#), [Output 19.1.3](#), and [Output 19.1.5](#)). Time deposits are also substitutes for S&L shares in the time deposit demand equation (see [Output 19.1.4](#)), while these liquid assets are independent of each other in [Output 19.1.5](#) (insignificant coefficient estimate of RT, -0.02705). Demand deposits and time deposits appear to be weak complements in [Output 19.1.3](#) and [Output 19.1.4](#), while the cross elasticities between demand deposits and time deposits are not significant in [Output 19.1.2](#) and [Output 19.1.5](#).

Example 19.2: The Airline Cost Data: Fixtwo Model

The Christenson Associates airline data are a frequently cited data set (see Greene 2000). The data measure costs, prices of inputs, and utilization rates for six airlines over the time span 1970–1984. This example analyzes the log transformations of the cost, price and quantity, and the raw (not logged) capacity utilization measure. You speculate the following model:

$$\ln(TC_{it}) = \alpha_N + \gamma_T + (\alpha_i - \alpha_N) + (\gamma_t - \gamma_T) + \beta_1 \ln(Q_{it}) + \beta_2 \ln(PF_{it}) + \beta_3 LF_{it} + \epsilon_{it}$$

where the α are the pure cross-sectional effects and γ are the time effects. The actual model speculated is highly nonlinear in the original variables. It would look like the following:

$$TC_{it} = \exp(\alpha_i + \gamma_t + \beta_3 LF_{it} + \epsilon_{it}) Q_{it}^{\beta_1} PF_{it}^{\beta_2}$$

The data and preliminary SAS statements are:

```
data airline;
  input  Obs I T C Q PF LF;
  label obs = "Observation number";
  label I = "Firm Number (CSID)";
  label T = "Time period (TSID)";
  label Q = "Output in revenue passenger miles (index)";
  label C = "Total cost, in thousands";
  label PF = "Fuel price";
  label LF = "Load Factor (utilization index)";
datalines;

... more lines ...
```

```

data airline;
  set airline;
  lC = log(C);
  lQ = log(Q);
  lPF = log(PF);
  label lC = "Log transformation of costs";
  label lQ = "Log transformation of quantity";
  label lPF= "Log transformation of price of fuel";
run;

```

The following statements fit the model.

```

proc panel data=airline;
  id i t;
  model lC = lQ lPF LF / fixtwo;
run;

```

First, you see the model's description in [Output 19.2.1](#). The model is a two-way fixed-effects model. There are six cross sections and fifteen time observations.

Output 19.2.1 The Airline Cost Data—Model Description

The PANEL Procedure	
Fixed Two Way Estimates	
Dependent Variable: lC Log transformation of costs	
Model Description	
Estimation Method	FixTwo
Number of Cross Sections	6
Time Series Length	15

The R-square and degrees of freedom can be seen in [Table 19.2.2](#). On the whole, you see a large R-square, so there is a reasonable fit. The degrees of freedom of the estimate are 90 minus 14 time dummy variables minus 5 cross section dummy variables and 4 regressors.

Output 19.2.2 The Airline Cost Data—Fit Statistics

Fit Statistics			
SSE	0.1768	DFE	67
MSE	0.0026	Root MSE	0.0514
R-Square	0.9984		

The F test for fixed effects is shown in [Table 19.2.3](#). Testing the hypothesis that there are no fixed effects, you easily reject the null of poolability. There are group effects, or time effects, or both. The test is highly significant. OLS would not give reasonable results.

Output 19.2.3 The Airline Cost Data—Test for Fixed Effects

F Test for No Fixed Effects			
Num DF	Den DF	F Value	Pr > F
19	67	23.10	<.0001

Looking at the parameters, you see a more complicated pattern. Most of the cross-sectional effects are highly significant (with the exception of CS2). This means that the cross sections are significantly different from the sixth cross section. Many of the time effects show significance, but this is not uniform. It looks like the significance might be driven by a large 16th period effect, since the first six time effects are negative and of similar magnitude. The time dummy variables taper off in size and lose significance from time period 12 onward. There are many causes to which you could attribute this decay of time effects. The time period of the data spans the OPEC oil embargoes and the dissolution of the Civil Aeronautics Board (CAB). These two forces are two possible reasons to observe the decay and parameter instability. As for the regression parameters, you see that quantity affects cost positively, and the price of fuel has a positive effect, but load factors negatively affect the costs of the airlines in this sample. The somewhat disturbing result is that the fuel cost is not significant. If the time effects are proxies for the effect of the oil embargoes, then an insignificant fuel cost parameter would make some sense. If the dummy variables proxy for the dissolution of the CAB, then the effect of load factors is also not being precisely estimated.

ODS Graphics Plots

ODS graphics plots can be obtained to graphically analyze the results. The following statements show how to generate the plots. If the PLOTS=ALL option is specified, all available plots are produced in two panels. For a complete list of options, see the section “ODS Graphics” on page 1367.

```
proc panel data=airline;
  id i t;
  model lC = lQ lPF lF / fixtwo plots = all;
run;
```

The preceding statements result in plots shown in [Output 19.2.5](#) and [Output 19.2.6](#).

Output 19.2.5 Diagnostic Panel 1

Output 19.2.6 Diagnostic Panel 2

The UNPACK and ONLY options produce individual detail images of paneled plots. The graph shown in [Output 19.2.7](#) shows a detail plot of residuals by cross section. The packed version always puts all cross sections on one plot while the unpacked one shows the cross sections in groups of ten to avoid loss of detail.

```
proc panel data=airline;
  id i t;
  model lC = lQ lPF lF / fixtwo plots(unpack only) = residsurface;
run;
```

Output 19.2.7 Surface Plot of the Residual

Example 19.3: The Airline Cost Data: Further Analysis

Using the same data as in Example 19.2, you further investigate the ‘true’ effect of fuel prices. Specifically, you run the FixOne model, ignoring time effects. You specify the following statements in PROC PANEL to run this model:

```
proc panel data=airline;
  id i t;
  model lC = lQ lPF LF / fixone;
run;
```

The preceding statements result in Output 19.3.1. The fit seems to have deteriorated somewhat. The SSE rises from 0.1768 to 0.2926.

Output 19.3.1 The Airline Cost Data—Fit Statistics

The PANEL Procedure			
Fixed One Way Estimates			
Dependent Variable: 1C Log transformation of costs			
Fit Statistics			
SSE	0.2926	DFE	81
MSE	0.0036	Root MSE	0.0601
R-Square	0.9974		

You still reject poolability based on the F test in [Output 19.3.2](#) at all accepted levels of significance.

Output 19.3.2 The Airline Cost Data—Test for Fixed Effects

F Test for No Fixed Effects			
Num DF	Den DF	F Value	Pr > F
5	81	57.74	<.0001

The parameters change somewhat dramatically as shown in [Output 19.3.3](#). The effect of fuel costs comes in very strong and significant. The load factor's coefficient increases, although not as dramatically. This suggests that the fixed time effects might be proxies for both the oil shocks and deregulation.

Output 19.3.3 The Airline Cost Data—Parameter Estimates

Example 19.4: The Airline Cost Data: Random-Effects Models

This example continues to use the Christenson Associates airline data, which measures costs, prices of inputs, and utilization rates for six airlines over the time span 1970–1984. There are six cross sections and fifteen time observations. Here, you examine the different estimates generated from the one-way random-effects and two-way random-effects models, by using four different methods to estimate the variance components: Fuller and Battese, Wansbeek and Kapteyn, Wallace and Hussain, and Nerlove.

The data for this example is created by the PROC PANEL statements shown in [Example 19.2](#). The PROC PANEL statements necessary to generate the estimates are as follows:

```
proc panel data=airline outest=estimates;
  id I T;
  RANONE:   model 1C = 1Q 1PF 1F / ranone vcomp=fb;
  RANONEwk: model 1C = 1Q 1PF 1F / ranone vcomp=wk;
  RANONEwh: model 1C = 1Q 1PF 1F / ranone vcomp=wh;
  RANONEnl: model 1C = 1Q 1PF 1F / ranone vcomp=nl;
  RANTWO:   model 1C = 1Q 1PF 1F / rantwo vcomp=fb;
  RANTWOwk: model 1C = 1Q 1PF 1F / rantwo vcomp=wk;
  RANTWOwh: model 1C = 1Q 1PF 1F / rantwo vcomp=wh;
  RANTWOnl: model 1C = 1Q 1PF 1F / rantwo vcomp=nl;
  POOLED:   model 1C = 1Q 1PF 1F / pooled;
  BTWNG:    model 1C = 1Q 1PF 1F / btwng;
  BTWNT:    model 1C = 1Q 1PF 1F / btwnt;
run;

data table;
  set estimates;
  VarCS = round(_VARCS_, .00001);
  VarTS = round(_VARTS_, .00001);
  VarErr = round(_VARERR_, .00001);
  Int = round(Intercept, .0001);
  1Q2 = round(1Q, .0001);
  1PF2 = round(1PF, .0001);
  1F2 = round(1F, .0001);
  if _n_ >= 9 then do;
    VarCS = . ;
    VarTS = . ;
  end;
  keep _MODEL_ _METHOD_ VarCS VarTS VarErr Int 1Q2 1PF2 1F2;
run;
```

The parameter estimates and variance components for both models are reported in [Output 19.4.1](#) and [Output 19.4.2](#).

In the random-effects model, individual constant terms are viewed as randomly distributed across cross-sectional units and not as parametric shifts of the regression function, as in the fixed-effects model. This is appropriate when the sampled cross-sectional units are drawn from a large population. Clearly, in this example, the six airlines are a sample of all the airlines in the industry and not an exhaustive, or nearly exhaustive, list.

There are four ways of computing the variance components in the one-way random-effects model. The method by Fuller and Battese (1974) (FB), uses a “fitting of constants” methods to estimate them. The Wansbeek and Kapteyn (1989) (WK) method uses the true disturbances, while the Wallace and Hussain (WH) method uses ordinary least squares residuals.

Looking at the estimates of the variance components for cross section and error in [Output 19.4.2](#), you see that equal variance components for error are computed for both FB and WK, while WH and NL are nearly equal.

All four techniques produce different variance components for cross sections. These estimates are then used to estimate the values of the parameters in [Output 19.4.1](#). All the parameters appear to have similar and equally plausible estimates. Both the index for output in revenue passenger miles (IQ) and fuel price (IPF) have small, positive effects on total costs, which you would expect. The load factor (LF) has a somewhat larger and negative effect on total costs, suggesting that as utilization increases, costs decrease.

As in the one-way random-effects model, the variance components for error produced by the FB and WK methods are equal. However, in this case, the WH and NL methods produce variance estimates that are dissimilar. The estimates of the variance component for cross sections are all different, but in a close range. The same cannot be said for the variance component for time series. As varied as each of the variance estimates may be, they produce parameter estimates that are similar and plausible. As with the one-way effects model, the index for output (IQ) and fuel price (IPF) are small and positive. The load factor (LF) estimates are all negative and, with the exception of the estimate produced by the WH method, somewhat smaller than the estimates produced in the one-way model. During the time the data were collected, the Civil Aeronautics Board dissolved, so it is possible that the dummy variables are proxies for this dissolution. This would lead to the decay of time effects and an imprecise estimation of the effects of the load factors, even though the estimates are statistically significant.

The pooled estimates give you something to compare the random-effects estimates against. You see that signs and magnitudes of output and fuel price are similar but that the magnitude of the load factor coefficient is somewhat larger under pooling. Since the model appears to have both cross-sectional and time series effects, the pooled model should not be used.

Finally, you examine the between groups estimators. For the between groups estimate, you are looking at each airline's data averaged across time. You see in [Output 19.4.1](#) that the between groups parameter estimates are radically different from all other parameter estimates. This could indicate that the time component is not being appropriately handled with this technique. For the between times estimate, you are looking at the average across all airlines in each time period. In this case, the parameter estimates are of the same sign and closer in magnitude to the previously computed estimates. Both the output and load factor effects appear to have more bearing on total costs.

Example 19.5: Using the FLATDATA Statement

Sometimes the data can be found in compressed form, where each line consists of all observations for the dependent and independent variables for the cross section. To illustrate, suppose you have a data set with 20 cross sections where each cross section consists of observations for six time periods. Each time period has values for dependent and independent variables $Y_1 \dots Y_6$ and $X_1 \dots X_6$. The *cs* and *num* variables represent other character and numeric variables that are constant across each cross section.

The observations for first five cross sections along with other variables are shown in [Output 19.5.1](#). In this example, *i* represents the cross section. The time period is identified by the subscript on the *Y* and *X* variables; it ranges from 1 to 6.

Since the PANEL procedure cannot work directly with the data in compressed form, the FLATDATA statement can be used to transform the data. The OUT= option can be used to output transformed data to a data set.

```
proc panel data=flattest;
  flatdata indid=i tsname="t" base=(X Y)
    keep=( cs num seed ) / out=flat_out;
  id i t;
  model y = x / fixone noint;
run;
```

First, six observations for the uncompressed data set and results for the one-way fixed-effects model fitted are shown in [Output 19.5.2](#) and [Output 19.5.3](#).

Output 19.5.2 Uncompressed Data Set

Example 19.6: The Cigarette Sales Data: Dynamic Panel Estimation with GMM

In this example, a dynamic panel demand model for cigarette sales is estimated. It illustrates the application of the method described in the section “Dynamic Panel Estimator” on page 1352. The data are a panel from 46 American states over the period 1963–92. See Baltagi and Levin (1992) and Baltagi (1995) for data description. All variables were transformed by taking the natural logarithm. The data set CIGAR is shown in the following statements.

```
data cigar;
  input state year price pop pop_16 cpi ndi sales pimin;
  label
    state = 'State abbreviation'
    year  = 'YEAR'
    price = 'Price per pack of cigarettes'
    pop   = 'Population'
    pop_16 = 'Population above the age of 16'
    cpi   = 'Consumer price index with (1983=100)'
    ndi   = 'Per capita disposable income'
    sales = 'Cigarette sales in packs per capita'
    pimin = 'Minimum price in adjoining states per pack of cigarettes';
  datalines;
1 63 28.6 3383 2236.5 30.6 1558.3045298 93.9 26.1
1 64 29.8 3431 2276.7 31.0 1684.0732025 95.4 27.5
1 65 29.8 3486 2327.5 31.5 1809.8418752 98.5 28.9
1 66 31.5 3524 2369.7 32.4 1915.1603572 96.4 29.5
1 67 31.6 3533 2393.7 33.4 2023.5463678 95.5 29.6
1 68 35.6 3522 2405.2 34.8 2202.4855362 88.4 32
1 69 36.6 3531 2411.9 36.7 2377.3346665 90.1 32.8
1 70 39.6 3444 2394.6 38.8 2591.0391591 89.8 34.3
1 71 42.7 3481 2443.5 40.5 2785.3159706 95.4 35.8

... more lines ...
```

The following statements sort the data by STATE and YEAR variables.

```
proc sort data=cigar;
  by state year;
run;
```

Next, logarithms of the variables required for regression estimation are calculated, as shown in the following statements:

```
data cigar;
  set cigar;
  lsales = log(sales);
  lprice = log(price);
  lndi   = log(ndi);
  lpimin = log(pimin);
  label lprice = 'Log price per pack of cigarettes';
```

```

label lndi = 'Log per capita disposable income';
label lsales = 'Log cigarette sales in packs per capita';
label lpimin = 'Log minimum price in adjoining states
               per pack of cigarettes';

run;

```

The following statements create the CIGAR_LAG data set with lagged variable for each cross section.

```

proc panel data=cigar;
  id state year;
  clag lsales(1) / out=cigar_lag;
run;

data cigar_lag;
  set cigar_lag;
  label lsales_1 = 'Lagged log cigarette sales in packs per capita';
run;

```

Finally, the model is estimated by a two step GMM method. Five lags (MAXBAND=5) of the dependent variable are used as instruments. NOLEVELS options is specified to avoid use of level equations, as shown in the following statements:

```

proc panel data=cigar_lag;
  inst depvar;
  model lsales = lsales_1 lprice lndi lpimin
    / gmm nolevels twostep maxband=5;
  id state year;
run;

```

Overview: PDLREG Procedure

The PDLREG procedure estimates regression models for time series data in which the effects of some of the regressor variables are distributed across time. The distributed lag model assumes that the effect of an input variable X on an output Y is distributed over time. If you change the value of X at time t , Y will experience some immediate effect at time t , and it will also experience a delayed effect at times $t + 1$, $t + 2$, and so on up to time $t + p$ for some limit p .

The regression model supported by PROC PDLREG can include any number of regressors with distribution lags and any number of covariates. (Simple regressors without lag distributions are called

covariates.) For example, the two-regressor model with a distributed lag effect for one regressor is written

$$y_t = \alpha + \sum_{i=0}^p \beta_i x_{t-i} + \gamma z_t + u_t$$

Here, x_t is the regressor with a distributed lag effect, z_t is a simple covariate, and u_t is an error term.

The distribution of the lagged effects is modeled by Almon lag polynomials. The coefficients b_i of the lagged values of the regressor are assumed to lie on a polynomial curve. That is,

$$b_i = \alpha_0^* + \sum_{j=1}^d \alpha_j^* i^j$$

where $d(\leq p)$ is the degree of the polynomial. For the numerically efficient estimation, the PDLREG procedure uses *orthogonal polynomials*. The preceding equation can be transformed into orthogonal polynomials:

$$b_i = \alpha_0 + \sum_{j=1}^d \alpha_j f_j(i)$$

where $f_j(i)$ is a polynomial of degree j in the lag length i , and α_j is a coefficient estimated from the data.

The PDLREG procedure supports endpoint restrictions for the polynomial. That is, you can constrain the estimated polynomial lag distribution curve so that $b_{-1} = 0$ or $b_{p+1} = 0$, or both. You can also impose linear restrictions on the parameter estimates for the covariates.

You can specify a minimum degree and a maximum degree for the lag distribution polynomial, and the procedure fits polynomials for all degrees in the specified range. (However, if distributed lags are specified for more than one regressor, you can specify a range of degrees for only one of them.)

The PDLREG procedure can also test for autocorrelated residuals and perform autocorrelated error correction by using the autoregressive error model. You can specify any order autoregressive error model and can specify several different estimation methods for the autoregressive model, including exact maximum likelihood.

The PDLREG procedure computes generalized Durbin-Watson statistics to test for autocorrelated residuals. For models with lagged dependent variables, the procedure can produce Durbin h and Durbin t statistics. You can request significance level p -values for the Durbin-Watson, Durbin h , and Durbin t statistics. See Chapter 8, “[The AUTOREG Procedure](#),” for details about these statistics.

The PDLREG procedure assumes that the input observations form a time series. Thus, the PDLREG procedure should be used only for ordered and equally spaced time series data.

Getting Started: PDLREG Procedure

Use the MODEL statement to specify the regression model. The PDLREG procedure’s MODEL statement is written like MODEL statements in other SAS regression procedures, except that a regressor can be followed by a lag distribution specification enclosed in parentheses.

For example, the following MODEL statement regresses Y on X and Z and specifies a distributed lag for X:

```
model y = x(4,2) z;
```

The notation X(4,2) specifies that the model includes X and 4 lags of X, with the coefficients of X and its lags constrained to follow a second-degree (quadratic) polynomial. Thus, the regression model specified by this MODEL statement is

$$y_t = a + b_0x_t + b_1x_{t-1} + b_2x_{t-2} + b_3x_{t-3} + b_4x_{t-4} + cz_t + u_t$$

$$b_i = \alpha_0 + \alpha_1 f_1(i) + \alpha_2 f_2(i)$$

where $f_1(i)$ is a polynomial of degree 1 in i and $f_2(i)$ is a polynomial of degree 2 in i .

Lag distribution specifications are enclosed in parentheses and follow the name of the regressor variable. The general form of the lag distribution specification is

regressor-name (length, degree, minimum-degree, end-constraint)

where

<i>length</i>	is the length of the lag distribution—that is, the number of lags of the regressor to use.
<i>degree</i>	is the degree of the distribution polynomial.
<i>minimum-degree</i>	is an optional minimum degree for the distribution polynomial.
<i>end-constraint</i>	is an optional endpoint restriction specification, which can have the value FIRST, LAST, or BOTH.

If the *minimum-degree* option is specified, the PDLREG procedure estimates models for all degrees between *minimum-degree* and *degree*.

Introductory Example

The following statements generate simulated data for variables Y and X. Y depends on the first three lags of X, with coefficients .25, .5, and .25. Thus, the effect of changes of X on Y takes effect 25% after one period, 75% after two periods, and 100% after three periods.

```
data test;
  x11 = 0; x12 = 0; x13 = 0;
  do t = -3 to 100;
    x = ranuni(1234);
    y = 10 + .25 * x11 + .5 * x12 + .25 * x13
        + .1 * rannor(1234);
    if t > 0 then output;
    x13 = x12; x12 = x11; x11 = x;
  end;
run;
```

The following statements use the PDLREG procedure to regress Y on a distributed lag of X . The length of the lag distribution is 4, and the degree of the distribution polynomial is specified as 3.

```
proc pdlreg data=test;
  model y = x( 4, 3 );
run;
```

The PDLREG procedure first prints a table of statistics for the residuals of the model, as shown in Figure 20.1. See Chapter 8, “The AUTOREG Procedure,” for an explanation of these statistics.

Figure 20.1 Residual Statistics

The PDLREG Procedure			
Dependent Variable		y	
Ordinary Least Squares Estimates			
SSE	0.86604442	DFE	91
MSE	0.00952	Root MSE	0.09755
SBC	-156.72612	AIC	-169.54786
MAE	0.07761107	AICC	-168.88119
MAPE	0.73971576	HQC	-164.3651
Durbin-Watson	1.9920	Regress R-Square	0.7711
		Total R-Square	0.7711

The PDLREG procedure next prints a table of parameter estimates, standard errors, and t tests, as shown in Figure 20.2.

Figure 20.2 Parameter Estimates

Parameter Estimates					
Variable	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	10.0030	0.0431	231.87	<.0001
x**0	1	0.4406	0.0378	11.66	<.0001
x**1	1	0.0113	0.0336	0.34	0.7377
x**2	1	-0.4108	0.0322	-12.75	<.0001
x**3	1	0.0331	0.0392	0.84	0.4007

The table in Figure 20.2 shows the model intercept and the estimated parameters of the lag distribution polynomial. The parameter labeled X**0 is the constant term, α_0 , of the distribution polynomial. X**1 is the linear coefficient, α_1 ; X**2 is the quadratic coefficient, α_2 ; and X**3 is the cubic coefficient, α_3 .

The parameter estimates for the distribution polynomial are not of interest in themselves. Since the PDLREG procedure does not print the orthogonal polynomial basis that it constructs to represent the distribution polynomial, these coefficient values cannot be interpreted.

However, because these estimates are for an orthogonal basis, you can use these results to test the degree of the polynomial. For example, this table shows that the X^3 estimate is not significant; the p -value for its t ratio is 0.4007, while the X^2 estimate is highly significant ($p < .0001$). This indicates that a second-degree polynomial might be more appropriate for this data set.

The PDLREG procedure next prints the lag distribution coefficients and a graphical display of these coefficients, as shown in [Figure 20.3](#).

Figure 20.3 Coefficients and Graph of Estimated Lag Distribution

x(2)	0.416661	0.0239	17.45	<.0001
x(3)	0.289482	0.0315	9.20	<.0001
x(4)	-0.004926	0.0365	-0.13	0.8929

Estimate of Lag Distribution		
Variable	-0.04	0.4167
x(0)	***	
x(1)	*****	
x(2)	*****	
x(3)	*****	
x(4)		

The lag distribution coefficients are the coefficients of the lagged values of X in the regression model. These coefficients lie on the polynomial curve defined by the parameters shown in [Figure 20.2](#). Note that the estimated values for $X(1)$, $X(2)$, and $X(3)$ are highly significant, while $X(0)$ and $X(4)$ are not significantly different from 0. These estimates are reasonably close to the true values used to generate the simulated data.

The graphical display of the lag distribution coefficients plots the estimated lag distribution polynomial reported in [Figure 20.2](#). The roughly quadratic shape of this plot is another indication that a third-degree distribution curve is not needed for this data set.

Syntax: PDLREG Procedure

The following statements can be used with the PDLREG procedure:

PROC PDLREG *option* ;
BY *variables* ;
MODEL *dependents = effects / options* ;
OUTPUT OUT= *SAS-data-set keyword = variables* ;
RESTRICT *restrictions* ;

Functional Summary

The statements and options used with the PDLREG procedure are summarized in the following table.

Table 20.1 PDLREG Functional Summary

PROC PDLREG Statement

PROC PDLREG *option* ;

The PROC PDLREG statement has the following option:

DATA= *SAS-data-set*

specifies the name of the SAS data set containing the input data. If you do not specify the DATA= option, the most recently created SAS data set is used.

In addition, you can place any of the following MODEL statement options in the PROC PDLREG statement, which is equivalent to specifying the option for every MODEL statement: ALL, COEF, CONVERGE=, CORRB, COVB, DW=, DWPROB, GINV, ITPRINT, MAXITER=, METHOD=, NOINT, NOPRINT, and PARTIAL.

BY Statement

BY *variables* ;

A BY statement can be used with PROC PDLREG to obtain separate analyses on observations in groups defined by the BY variables.

MODEL Statement

MODEL *dependent = effects / options* ;

The MODEL statement specifies the regression model. The keyword MODEL is followed by the dependent variable name, an equal sign, and a list of independent effects. Only one MODEL statement is allowed.

Every variable in the model must be a numeric variable in the input data set. Specify an independent effect with a variable name optionally followed by a polynomial lag distribution specification.

Specifying Independent Effects

The general form of an effect is

variable (*length, degree, minimum-degree, constraint*)

The term in parentheses following the variable name specifies a polynomial distributed lag (PDL) for the variable. The PDL specification is as follows:

<i>length</i>	specifies the number of lags of the variable to include in the lag distribution.
<i>degree</i>	specifies the maximum degree of the distribution polynomial. If not specified, the degree defaults to the lag length.
<i>minimum-degree</i>	specifies the minimum degree of the polynomial. By default <i>minimum-degree</i> is the same as <i>degree</i> .
<i>constraint</i>	specifies endpoint restrictions on the polynomial. The value of <i>constraint</i> can be FIRST, LAST, or BOTH. If a value is not specified, there are no endpoint restrictions.

If you do not specify the *degree* or *minimum-degree* parameter, but you do specify endpoint restrictions, you must use commas to show which parameter, *degree* or *minimum-degree*, is left out.

MODEL Statement Options

The following options can appear in the MODEL statement after a slash (/).

ALL

prints all the matrices computed during the analysis of the model.

COEF

prints the transformation coefficients for the first p observations. These coefficients are formed from a scalar multiplied by the inverse of the Cholesky root of the Toeplitz matrix of autocovariances.

CORRB

prints the matrix of estimated correlations between the parameter estimates.

COVB

prints the matrix of estimated covariances between the parameter estimates.

DW= j

prints the generalized Durbin-Watson statistics up to the order of j . The default is DW=1. When you specify the LAGDEP or LAGDEP=*name* option, the Durbin-Watson statistic is not printed unless you specify the DW= option.

DWPROB

prints the marginal probability of the Durbin-Watson statistic.

CONVERGE= *value*

sets the convergence criterion. If the maximum absolute value of the change in the autoregressive parameter estimates between iterations is less than this amount, then convergence is assumed. The default is CONVERGE=.001.

GINV

prints the inverse of the Toeplitz matrix of autocovariances for the Yule-Walker solution.

I

prints $(\mathbf{X}'\mathbf{X})^{-1}$, the inverse of the crossproducts matrix for the model; or, if restrictions are specified, it prints $(\mathbf{X}'\mathbf{X})^{-1}$ adjusted for the restrictions.

ITPRINT

prints information on each iteration.

LAGDEP**LAGDV**

prints the t statistic for testing residual autocorrelation when regressors contain lagged dependent variables.

LAGDEP= *name***LAGDV= *name***

prints the Durbin h statistic for testing the presence of first-order autocorrelation when regressors contain the lagged dependent variable whose name is specified as LAGDEP=*name*. When the h statistic cannot be computed, the asymptotically equivalent t statistic is given.

MAXITER= *number*

sets the maximum number of iterations allowed. The default is MAXITER=50.

METHOD= *value*

specifies the type of estimates for the autoregressive component. The values of the METHOD= option are as follows:

METHOD=ML	specifies the maximum likelihood method.
METHOD=ULS	specifies unconditional least squares.
METHOD=YW	specifies the Yule-Walker method.
METHOD=ITYW	specifies iterative Yule-Walker estimates.

The default is METHOD=ML if you specified the LAGDEP or LAGDEP= option; otherwise, METHOD=YW is the default.

NLAG= *m***NLAG=** (*number-list*)

specifies the order of the autoregressive process or the subset of autoregressive lags to be fit. If you do not specify the NLAG= option, PROC PDLREG does not fit an autoregressive model.

NOINT

suppresses the intercept parameter from the model.

NOPRINT

suppresses the printed output.

PARTIAL

prints partial autocorrelations if the NLAG= option is specified.

STB

prints standardized parameter estimates. Sometimes known as a standard partial regression coefficient, a *standardized parameter estimate* is a parameter estimate multiplied by the standard deviation of the associated regressor and divided by the standard deviation of the regressed variable.

XPX

prints the crossproducts matrix, $\mathbf{X}'\mathbf{X}$, used for the model. \mathbf{X} refers to the transformed matrix of regressors for the regression.

OUTPUT Statement

OUTPUT *OUT= SAS-data-set keyword= option ... ;*

The OUTPUT statement creates an output SAS data set with variables as specified by the following keyword options. See the section “Predicted Values” in Chapter 8, “The AUTOREG Procedure,” for a description of the associated computations for these options.

ALPHACLI= *number*

sets the confidence limit size for the estimates of future values of the current realization of the response time series to *number*, where *number* is less than one and greater than zero. The resulting confidence interval has 1-*number* confidence. The default value for *number* is 0.05, corresponding to a 95% confidence interval.

ALPHACL= *number*

sets the confidence limit size for the estimates of the structural or regression part of the model to *number*, where *number* is less than one and greater than zero. The resulting confidence interval has 1-*number* confidence. The default value for *number* is 0.05, corresponding to a 95% confidence interval.

OUT= *SAS-data-set*

names the output data.

The following specifications are of the form *KEYWORD=names*, where *KEYWORD=* specifies the statistic to include in the output data set and *names* gives names to the variables that contain the statistics.

CONSTANT= *variable*

writes the transformed intercept to the output data set.

LCL= *name*

requests that the lower confidence limit for the predicted value (specified in the *PREDICTED=* option) be added to the output data set under the name given.

LCLM= *name*

requests that the lower confidence limit for the structural predicted value (specified in the *PREDICTEDM=* option) be added to the output data set under the name given.

PREDICTED= *name***P=** *name*

stores the predicted values in the output data set under the name given.

PREDICTEDM= *name***PM=** *name*

stores the structural predicted values in the output data set under the name given. These values are formed from only the structural part of the model.

RESIDUAL= *name***R=** *name*

stores the residuals from the predicted values based on both the structural and time series parts of the model in the output data set under the name given.

RESIDUALM= *name***RM=** *name*

requests that the residuals from the structural prediction be given.

TRANSFORM= *variables*

requests that the specified variables from the input data set be transformed by the autoregressive model and put in the output data set. If you need to reproduce the data suitable for reestimation, you must also transform an intercept variable. To do this, transform a variable that only takes the value 1 or use the **CONSTANT=** option.

UCL= *name*

stores the upper confidence limit for the predicted value (specified in the **PREDICTED=** option) in the output data set under the name given.

UCLM= *name*

stores the upper confidence limit for the structural predicted value (specified in the **PREDICTEDM=** option) in the output data set under the name given.

For example, the SAS statements

```
proc pdlreg data=a;
  model y=x1 x2;
  output out=b p=yhat r=resid;
run;
```

create an output data set named B. In addition to the input data set variables, the data set B contains the variable YHAT, whose values are predicted values of the dependent variable Y, and RESID, whose values are the residual values of Y.

RESTRICT Statement

RESTRICT *equation* , ... , *equation* ;

The **RESTRICT** statement places restrictions on the parameter estimates for covariates in the preceding **MODEL** statement. A parameter produced by a distributed lag cannot be restricted with the **RESTRICT** statement.

Each restriction is written as a linear equation. If you specify more than one restriction in a **RESTRICT** statement, the restrictions are separated by commas.

You can refer to parameters by the name of the corresponding regressor variable. Each name used in the equation must be a regressor in the preceding **MODEL** statement. Use the keyword **INTERCEPT** to refer to the intercept parameter in the model.

RESTRICT statements can be given labels. You can use labels to distinguish results for different restrictions in the printed output. Labels are specified as follows:

label : **RESTRICT** ...

The following is an example of the use of the RESTRICT statement, in which the coefficients of the regressors X1 and X2 are required to sum to 1:

```
proc pdlreg data=a;
  model y = x1 x2;
  restrict x1 + x2 = 1;
run;
```

Parameter names can be multiplied by constants. When no equal sign appears, the linear combination is set equal to 0. Note that the parameters associated with the variables are restricted, not the variables themselves. Here are some examples of valid RESTRICT statements:

```
restrict x1 + x2 = 1;
restrict x1 + x2 - 1;
restrict 2 * x1 = x2 + x3 , intercept + x4 = 0;
restrict x1 = x2 = x3 = 1;
restrict 2 * x1 - x2;
```

Restricted parameter estimates are computed by introducing a Lagrangian parameter λ for each restriction (Pringle and Rayner 1971). The estimates of these Lagrangian parameters are printed in the parameter estimates table. If a restriction cannot be applied, its parameter value and degrees of freedom are listed as 0.

The Lagrangian parameter, λ , measures the sensitivity of the SSE to the restriction. If the restriction is changed by a small amount ϵ , the SSE is changed by $2\lambda\epsilon$.

The t ratio tests the significance of the restrictions. If λ is zero, the restricted estimates are the same as the unrestricted ones.

You can specify any number of restrictions in a RESTRICT statement, and you can use any number of RESTRICT statements. The estimates are computed subject to all restrictions specified. However, restrictions should be consistent and not redundant.

Details: PDLREG Procedure

Missing Values

The PDLREG procedure skips any observations at the beginning of the data set that have missing values. The procedure uses all observations with nonmissing values for all the independent and dependent variables such that the lag distribution has sufficient nonmissing lagged independent variables.

Polynomial Distributed Lag Estimation

The simple finite distributed lag model is expressed in the form

$$y_t = \alpha + \sum_{i=0}^p \beta_i x_{t-i} + \epsilon_t$$

When the lag length (p) is long, severe multicollinearity can occur. Use the Almon or *polynomial distributed lag* model to avoid this problem, since the relatively low-degree d ($\leq p$) polynomials can capture the true lag distribution. The lag coefficient can be written in the Almon polynomial lag

$$\beta_i = \alpha_0^* + \sum_{j=1}^d \alpha_j^* i^j$$

Emerson (1968) proposed an efficient method of constructing orthogonal polynomials from the preceding polynomial equation as

$$\beta_i = \alpha_0 + \sum_{j=1}^d \alpha_j f_j(i)$$

where $f_j(i)$ is a polynomial of degree j in the lag length i . The polynomials $f_j(i)$ are chosen so that they are orthogonal:

$$\sum_{i=1}^n w_i f_j(i) f_k(i) = \begin{cases} 1 & \text{if } j = k \\ 0 & \text{if } j \neq k \end{cases}$$

where w_i is the weighting factor, and $n = p + 1$. PROC PDLREG uses the equal weights ($w_i = 1$) for all i . To construct the orthogonal polynomials, the following recursive relation is used:

$$f_j(i) = (A_j i + B_j) f_{j-1}(i) - C_j f_{j-2}(i) \quad j = 1, \dots, d$$

The constants A_j , B_j , and C_j are determined as follows:

$$A_j = \left\{ \sum_{i=1}^n w_i i^2 f_{j-1}^2(i) - \left(\sum_{i=1}^n w_i i f_{j-1}^2(i) \right)^2 - \left(\sum_{i=1}^n w_i i f_{j-1}(i) f_{j-2}(i) \right)^2 \right\}^{-1/2}$$

$$B_j = -A_j \sum_{i=1}^n w_i i f_{j-1}^2(i)$$

$$C_j = A_j \sum_{i=1}^n w_i i f_{j-1}(i) f_{j-2}(i)$$

where $f_{-1}(i) = 0$ and $f_0(i) = 1/\sqrt{\sum_{i=1}^n w_i}$.

PROC PDLREG estimates the orthogonal polynomial coefficients, $\alpha_0, \dots, \alpha_d$, to compute the coefficient estimate of each independent variable (X) with distributed lags. For example, if an independent variable is specified as X(9,3), a third-degree polynomial is used to specify the distributed lag coefficients. The third-degree polynomial is fit as a constant term, a linear term, a quadratic term, and a cubic term. The four terms are constructed to be orthogonal. In the output produced by the PDLREG procedure for this case, parameter estimates with names X**0, X**1, X**2, and X**3 correspond to $\hat{\alpha}_0, \hat{\alpha}_1, \hat{\alpha}_2$, and $\hat{\alpha}_3$, respectively. A test using the t statistic and the approximate p -value (“Approx Pr > | t ””) associated with X**3 can determine whether a second-degree polynomial rather than a third-degree polynomial is appropriate. The estimates of the 10 lag coefficients associated with the specification X(9,3) are labeled X(0), X(1), X(2), X(3), X(4), X(5), X(6), X(7), X(8), and X(9).

Autoregressive Error Model Estimation

The PDLREG procedure uses the same autoregressive error model estimation methods as the AUTOREG procedure. These two procedures share the same computational resources for computing estimates. See Chapter 8, “[The AUTOREG Procedure](#),” for details about estimation methods for autoregressive error models.

OUT= Data Set

The OUT= data set produced by the PDLREG procedure’s OUTPUT statement is similar in form to the OUT= data set produced by the AUTOREG procedure. See Chapter 8, “[The AUTOREG Procedure](#),” for details on the OUT= data set.

Printed Output

The PDLREG procedure prints the following items:

1. the name of the dependent variable
2. the ordinary least squares (OLS) estimates
3. the estimates of autocorrelations and of the autocovariance, and if line size permits, a graph of the autocorrelation at each lag. The autocorrelation for lag 0 is 1. These items are printed if you specify the NLAG= option.
4. the partial autocorrelations if the PARTIAL and NLAG= options are specified. The first partial autocorrelation is the autocorrelation for lag 1.
5. the preliminary mean square error, which results from solving the Yule-Walker equations if you specify the NLAG= option

6. the estimates of the autoregressive parameters, their standard errors, and the ratios of estimates to standard errors (t) if you specify the NLAG= option
7. the statistics of fit for the final model if you specify the NLAG= option. These include the error sum of squares (SSE), the degrees of freedom for error (DFE), the mean square error (MSE), the root mean square error (Root MSE), the mean absolute error (MAE), the mean absolute percentage error (MAPE), the Schwarz information criterion (SBC), the Akaike's information criterion (AIC), Akaike's information criterion corrected (AICC), the regression R^2 (Regress R-Square), the total R^2 (Total R-Square), and the Durbin-Watson statistic (Durbin-Watson). See Chapter 8, "The AUTOREG Procedure," for details of the regression R^2 and the total R^2 .
8. the parameter estimates for the structural model (B), a standard error estimate, the ratio of estimate to standard error (t), and an approximation to the significance probability for the parameter being 0 ("Approx Pr > | t |")
9. a plot of the lag distribution (estimate of lag distribution)
10. the covariance matrix of the parameter estimates if the COVB option is specified

ODS Table Names

PROC PDLREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 20.2 ODS Tables Produced in PROC PDLREG

ODS Table Name	Description	Option
ODS Tables Created by the MODEL Statement		
ARParameterEstimates	Estimates of autoregressive parameters	NLAG=
CholeskyFactor	Cholesky root of gamma	NLAG= and ALL
Coefficients	Coefficients for first NLAG observations	NLAG= and (COEF or ALL)
ConvergenceStatus	Convergence status table	default
CorrB	Correlation of parameter estimates	CORRB
CorrGraph	Estimates of autocorrelations	NLAG=
CovB	Covariance of parameter estimates	COVB
DependenceEquations	Linear dependence equation	
Dependent	Dependent variable	default

Restrict	Restriction table	default

Examples: PDLREG Procedure

Example 20.1: Industrial Conference Board Data

In this example, a second-degree Almon polynomial lag model is fit to a model with a five-period lag, and dummy variables are used for quarter effects. The PDL model is estimated using capital appropriations data series for the period 1952 to 1967. The estimation model is written

$$CE_t = a_0 + b_1 Q1_t + b_2 Q2_t + b_3 Q3_t + c_0 CA_t + c_1 CA_{t-1} + \dots + c_5 CA_{t-5}$$

where CE represents capital expenditures and CA represents capital appropriations.

The following statements use the REG procedure to fit the same polynomial distributed lag model. A DATA step computes lagged values of the regressor X, and RESTRICT statements are used to impose the polynomial lag distribution. Refer to Judge et al. (1985, pp. 357–359) for the restricted least squares estimation of the Almon distributed lag model.

```

Example 20.2: Money Demand Model

This example estimates the demand for money by using the following dynamic specification:

$$m_t = a_0 + b_0 m_{t-1} + \sum_{i=0}^5 c_i y_{t-i} + \sum_{i=0}^2 d_i r_{t-i} + \sum_{i=0}^3 f_i p_{t-i} + u_t$$

where

m_t = log of real money stock (M1)
 y_t = log of real GNP
 r_t = interest rate (commercial paper rate)
 p_t = inflation rate
 $c_i, d_i,$ and f_i ($i > 0$) are coefficients for the lagged variables

The following DATA step reads the data and transforms the real money and real GNP variables using the natural logarithm. Refer to Balke and Gordon (1986) for a description of the data.

```

data a;
  input m1 gnp gdf r @@;
  m   = log( 100 * m1 / gdf );
  lagm = lag( m );
  y   = log( gnp );
  p   = log( gdf / lag( gdf ) );
  date = intnx( 'qtr', '1jan1968'd, _n_-1 );
  format date yyqc6.;
  label m      = 'Real Money Stock (M1)'
        lagm   = 'Lagged Real Money Stock'
        y      = 'Real GNP'
        r      = 'Commercial Paper Rate'
        p      = 'Inflation Rate';
datalines;

... more lines ...

```

Output 20.2.1 shows a partial list of the data set.

Output 20.2.1 Partial List of the Data Set A

Overview: QLIM Procedure

The QLIM (qualitative and limited dependent variable model) procedure analyzes univariate and multivariate limited dependent variable models in which dependent variables take discrete values or dependent variables are observed only in a limited range of values. These models include logit, probit, tobit, selection, and multivariate models. The multivariate model can contain discrete choice and limited endogenous variables in addition to continuous endogenous variables.

The QLIM procedure supports the following models:

- linear regression model with heteroscedasticity
- Box-Cox regression with heteroscedasticity
- probit with heteroscedasticity
- logit with heteroscedasticity
- tobit (censored and truncated) with heteroscedasticity
- bivariate probit
- bivariate tobit
- sample selection and switching regression models
- multivariate limited dependent variables
- stochastic frontier production and cost models

In the linear regression models with heteroscedasticity, the assumption that error variance is constant across observations is relaxed. The QLIM procedure allows for a number of different linear and nonlinear variance specifications. Another way to make the linear model more appropriate to fit the data and reduce skewness is to apply Box-Cox transformation. If the nature of data is such that the dependent variable is discrete and it takes only two possible values, OLS estimates are inconsistent. The QLIM procedure offers probit and logit models to overcome these estimation problems. Assumptions about the error variance can also be relaxed in order to estimate probit or logit with heteroscedasticity.

The QLIM procedure also offers a class of models in which the dependent variable is censored or truncated from below or above or both. When a continuous dependent variable is observed only within a certain range and values outside this range are not available, the QLIM procedure offers a class of models that adjust for truncation. In some cases, the dependent variable is continuous only in a certain range and all values outside this range are reported as being on its boundary. For example, if it is not possible to observe negative values, the value of the dependent variable is reported as equal to zero. Because the data are censored, ordinary least squares (OLS) results are inconsistent, and it cannot be guaranteed that the predicted values from the model fall in the appropriate region.

Most of the models in the QLIM procedure can be extended to accommodate bivariate and multivariate scenarios. The assumption that one variable is observed only if another variable takes on certain values lead to the introduction of sample selection models. If the dependent variables are mutually exclusive and observed only for certain ranges of the selection variable, the sample selection can be extended to include cases of switching regression. Stochastic frontier production and cost models allow for random shocks of the production or cost. They include a systematic positive component in the error term that adjusts for technological or cost inefficiency.

The QLIM procedure uses maximum likelihood methods. Initial starting values for the nonlinear optimizations are typically calculated by OLS.

Getting Started: QLIM Procedure

The QLIM procedure is similar in use to the other regression or simultaneous equations model procedures in the SAS System. For example, the following statements are used to estimate a binary choice model by using the probit probability function:

```
proc qlim data=a;
  model y = x1;
  endogenous y ~ discrete;
run;
```

The response variable, y , is numeric and has discrete values. PROC QLIM enables the user to specify the type of endogenous variables in the ENDOGENOUS statement. The binary probit model can be also specified as follows:

```
model y = x1 / discrete;
```

When multiple endogenous variables are specified in the QLIM procedure, these equations are estimated as a system. Multiple endogenous variables can be specified with one MODEL statement in the QLIM procedure when these models have the same exogenous variables:

```
model y1 y2 = x1 x2 / discrete;
```

The preceding specification is equivalent to the following statements:

```
proc qlim data=a;
  model y1 = x1 x2;
  model y2 = x1 x2;
  endogenous y1 y2 ~ discrete;
run;
```

Some equations in multivariate models can be continuous while other equations can be discrete. A bivariate model with a discrete and a continuous equation is specified as follows:

```
proc qlim data=a;
  model y1 = x1 x2;
  model y2 = x3 x4;
  endogenous y1 ~ discrete;
run;
```

The standard tobit model is estimated by specifying the endogenous variable to be truncated or censored. The limits of the dependent variable can be specified with the CENSORED or TRUNCATED option in the ENDOGENOUS or MODEL statement when the data are limited by specific values or variables. For example, the two-limit censored model requires two variables that contain the lower (bottom) and upper (top) bound:

```
proc qlim data=a;
  model y = x1 x2 x3;
  endogenous y ~ censored(lb=bottom ub=top);
run;
```

The bounds can be numbers if they are fixed for all observations in the data set. For example, the standard tobit model can be specified as follows:

```
proc qlim data=a;
  model y = x1 x2 x3;
  endogenous y ~ censored(lb=0);
run;
```

Introductory Example: Binary Probit and Logit Models

The following example illustrates the use of PROC QLIM. The data were originally published by Mroz (1987) and downloaded from Wooldridge (2002). This data set is based on a sample of 753 married white women. The dependent variable is a discrete variable of labor force participation (`lnf`). Explanatory variables are the number of children ages 5 or younger (`kidst6`), the number of children ages 6 to 18 (`kidsge6`), the woman's age (`age`), the woman's years of schooling (`educ`), wife's labor experience (`exper`), square of experience (`expersq`), and the family income excluding the wife's wage (`nwifeinc`). The program (with data values omitted) is as follows:

```

/*-- Binary Probit --*/
proc qlim data=mroz;
  model inlf = nwifeinc educ exper expersq
            age kidslt6 kidsge6 / discrete;
run;

```

Results of this analysis are shown in the following four figures. In the first table, shown in [Figure 21.1](#), PROC QLIM provides frequency information about each choice. In this example, 428 women participate in the labor force ($\text{inlf} = 1$).

Figure 21.1 Choice Frequency Summary

Binary Data		
The QLIM Procedure		
Discrete Response Profile of inlf		
Index	Value	Total Frequency
1	0	325
2	1	428

The second table is the estimation summary table shown in [Figure 21.2](#). Included are the number of dependent variables, names of dependent variables, the number of observations, the log-likelihood function value, the maximum absolute gradient, the number of iterations, AIC, and Schwarz criterion.

Figure 21.2 Fit Summary Table of Binary Probit

Model Fit Summary	
Number of Endogenous Variables	1
Endogenous Variable	inlf
Number of Observations	753
Log Likelihood	-401.30219
Maximum Absolute Gradient	0.0000669
Number of Iterations	15
Optimization Method	Quasi-Newton
AIC	818.60439
Schwarz Criterion	855.59691

Goodness-of-fit measures are displayed in [Figure 21.3](#). All measures except McKelvey-Zavoina's definition are based on the log-likelihood function value. The likelihood ratio test statistic has chi-square distribution conditional on the null hypothesis that all slope coefficients are zero. In this example, the likelihood ratio statistic is used to test the hypothesis that $\text{kidslt6} = \text{kidge6} = \text{age} = \text{educ} = \text{exper} = \text{expersq} = \text{nwifeinc} = 0$.

Figure 21.3 Goodness of Fit

Goodness-of-Fit Measures		
Measure	Value	Formula
Likelihood Ratio (R)	227.14	$2 * (\text{LogL} - \text{LogL0})$
Upper Bound of R (U)	1029.7	$- 2 * \text{LogL0}$
Aldrich-Nelson	0.2317	$R / (R+N)$
Cragg-Uhler 1	0.2604	$1 - \exp(-R/N)$
Cragg-Uhler 2	0.3494	$(1 - \exp(-R/N)) / (1 - \exp(-U/N))$
Estrella	0.2888	$1 - (1 - R/U)^{(U/N)}$
Adjusted Estrella	0.2693	$1 - ((\text{LogL} - K) / \text{LogL0})^{(-2/N * \text{LogL0})}$
McFadden's LRI	0.2206	R / U
Veall-Zimmermann	0.4012	$(R * (U+N)) / (U * (R+N))$
McKelvey-Zavoina	0.4025	

N = # of observations, K = # of regressors

Finally, the parameter estimates and standard errors are shown in [Figure 21.4](#).

Figure 21.4 Parameter Estimates of Binary Probit

Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	0.270077	0.508590	0.53	0.5954
nwifeinc	1	-0.012024	0.004840	-2.48	0.0130
educ	1	0.130905	0.025255	5.18	<.0001
exper	1	0.123348	0.018720	6.59	<.0001
expersq	1	-0.001887	0.000600	-3.14	0.0017
age	1	-0.052853	0.008477	-6.24	<.0001
kidslt6	1	-0.868329	0.118519	-7.33	<.0001
kidsge6	1	0.036005	0.043477	0.83	0.4076

When the error term has a logistic distribution, the binary logit model is estimated. To specify a logistic distribution, add D=LOGIT option as follows:

```

/*-- Binary Logit --*/
proc qlim data=mroz;
  model inlf = nwifeinc educ exper expersq
              age kidslt6 kidsge6 / discrete(d=logit);
run;

```

The estimated parameters are shown in [Figure 21.5](#).

Figure 21.5 Parameter Estimates of Binary Logit

Binary Data					
The QLIM Procedure					
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	0.425452	0.860365	0.49	0.6210
nwifeinc	1	-0.021345	0.008421	-2.53	0.0113
educ	1	0.221170	0.043441	5.09	<.0001
exper	1	0.205870	0.032070	6.42	<.0001
expersq	1	-0.003154	0.001017	-3.10	0.0019
age	1	-0.088024	0.014572	-6.04	<.0001
kidslt6	1	-1.443354	0.203575	-7.09	<.0001
kidsge6	1	0.060112	0.074791	0.80	0.4215

The heteroscedastic logit model can be estimated using the HETERO statement. If the variance of the logit model is a function of the family income level excluding wife's income (nwifeinc), the variance can be specified as

$$\text{Var}(\epsilon_i) = \sigma^2 \exp(\gamma * \text{nwifeinc}_i)$$

where σ^2 is normalized to 1 because the dependent variable is discrete. The following SAS statements estimate the heteroscedastic logit model:

```

/*-- Binary Logit with Heteroscedasticity --*/
proc qlim data=mroz;
  model inlf = nwifeinc educ exper expersq
              age kidslt6 kidsge6 / discrete(d=logit);
  hetero inlf ~ nwifeinc / noconst;
run;

```

The parameter estimate, γ , of the heteroscedasticity variable is listed as _H.nwifeinc; see Figure 21.6.

_H.nwifeinc	1	0.013280	0.013606	0.98	0.3291

Syntax: QLIM Procedure

The QLIM procedure is controlled by the following statements:

```

PROC QLIM options ;
  BOUNDS bound1 < , bound2 ... > ;
  BY variables ;
  CLASS variables ;
  FREQ variable ;
  ENDOGENOUS variables ~ options ;
  HETERO dependent variables ~ exogenous variables / options ;
  INIT initvalue1 < , initvalue2 ... > ;
  MODEL dependent variables = regressors / options ;
  NLOPTIONS options ;
  OUTPUT options ;
  RESTRICT restriction1 < , restriction2 ... > ;
  TEST options ;
  WEIGHT variable ;

```

At least one MODEL statement is required. If more than one MODEL statement is used, the QLIM procedure estimates a system of models. If a FREQ or WEIGHT statement is specified more than once, the variable specified in the first instance is used. Main effects and higher-order terms can be specified in the MODEL statement, as in the GLM procedure and PROBIT procedure in SAS/STAT. If a CLASS statement is used, it must precede the MODEL statement.

Functional Summary

Table 21.1 summarizes the statements and options used with the QLIM procedure.

Table 21.1 QLIM Functional Summary

Description	Statement	Option
Data Set Options		
Specifies the input data set	QLIM	DATA=
Writes parameter estimates to an output data set	QLIM	OUTEST=
Writes predictions to an output data set	OUTPUT	OUT=
Declaring the Role of Variables		
Specifies BY-group processing	BY

PROC QLIM Statement

PROC QLIM *options* ;

The following options can be used in the PROC QLIM statement.

Data Set Options

DATA=SAS-data-set

specifies the input SAS data set. If the DATA= option is not specified, PROC QLIM uses the most recently created SAS data set.

Output Data Set Options

OUTEST=SAS-data-set

writes the parameter estimates to an output data set.

COVOUT

writes the covariance matrix for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is specified.

CORROUT

writes the correlation matrix for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is specified.

Printing Options

NOPRINT

suppresses the normal printed output but does not suppress error listings. If NOPRINT option is set, then any other print option is turned off.

PRINTALL

turns on all the printing-control options. The options set by PRINTALL are COVB and CORRB.

CORRB

prints the correlation matrix of the parameter estimates.

COVB

prints the covariance matrix of the parameter estimates.

ITPRINT

prints the initial parameter estimates, convergence criteria, and all constraints of the optimization. At each iteration, objective function value, step size, maximum gradient, and slope of search direction are printed as well.

Model Estimation Options

COVEST=covariance-option

specifies the method to calculate the covariance matrix of parameter estimates. The supported covariance types are as follows:

OP	specifies the covariance from the outer product matrix.
HESSIAN	specifies the covariance from the inverse Hessian matrix.
QML	specifies the covariance from the outer product and Hessian matrices (the quasi-maximum likelihood estimates).

The default is COVEST=HESSIAN.

NDRAW=*value*

specifies the number of draws for Monte Carlo integration.

SEED=*value*

specifies a seed for pseudo-random number generation in Monte Carlo integration.

Options to Control the Optimization Process

PROC QLIM uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. All the NLO options are available from the NLOPTIONS statement. For details, see Chapter 6, “Nonlinear Optimization Methods.”

METHOD=*value*

specifies the optimization method. If this option is specified, it overwrites the TECH= option in NLOPTIONS statement. Valid values are as follows:

CONGRA	performs a conjugate-gradient optimization
DBLDOG	performs a version of double-dogleg optimization
NMSIMP	performs a Nelder-Mead simplex optimization
NEWRAP	performs a Newton-Raphson optimization combining a line-search algorithm with ridging
NRRIDG	performs a Newton-Raphson optimization with ridging
QUANEW	performs a quasi-Newton optimization
TRUREG	performs a trust region optimization

The default method is METHOD=QUANEW.

BOUNDS Statement

BOUNDS *bound1* < , *bound2* ... > ;

The BOUNDS statement imposes simple boundary constraints on the parameter estimates. BOUNDS statement constraints refer to the parameters estimated by the QLIM procedure. Any number of BOUNDS statements can be specified.

Each *bound* is composed of parameters and constants and inequality operators. Parameters associated with regressor variables are referred to by the names of the corresponding regressor variables:

item operator item < operator item < operator item ... > >

Each *item* is a constant, the name of a parameter, or a list of parameter names. See the section “Naming of Parameters” on page 1463 for more details on how parameters are named in the QLIM procedure. Each *operator* is '<', '>', '<=', or '>='.

Both the BOUNDS statement and the RESTRICT statement can be used to impose boundary constraints; however, the BOUNDS statement provides a simpler syntax for specifying these kinds of constraints. See the “RESTRICT Statement” on page 1440 for more information.

The following BOUNDS statement constrains the estimates of the parameters associated with the variable *ttime* and the variables *x1* through *x10* to be between zero and one. This example illustrates the use of parameter lists to specify boundary constraints.

```
bounds 0 < ttime x1-x10 < 1;
```

The following BOUNDS statement constrains the estimates of the correlation (*_RHO*) and sigma (*_SIGMA*) in the bivariate model:

```
bounds _rho >= 0, _sigma.y1 > 1, _sigma.y2 < 5;
```

BY Statement

BY *variables* ;

A BY statement can be used with PROC QLIM to obtain separate analyses on observations in groups defined by the BY variables.

CLASS Statement

CLASS *variables* ;

The CLASS statement names the classification variables to be used in the analysis. Classification variables can be either character or numeric.

Class levels are determined from the formatted values of the CLASS variables. Thus, you can use formats to group values into levels. See the discussion of the FORMAT procedure in *SAS Language Reference: Dictionary* for details.

ENDOGENOUS Statement

ENDOGENOUS *variables* ~ *options* ;

The ENDOGENOUS statement specifies the type of dependent variables that appear on the left-hand side of the equation. Endogenous variables listed refer to the dependent variables that appear on the left-hand side of the equation. Currently, no right-hand side endogeneity is handled in PROC QLIM. All variables appearing on the right-hand side of the equation are treated as exogenous.

Discrete Variable Options

DISCRETE < (*discrete-options*) >

specifies that the endogenous variables in this statement are discrete. Valid *discrete-options* are as follows:

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sorting order for the levels of the discrete variables specified in the ENDOGENOUS statement. This ordering determines which parameters in the model correspond to each level in the data. The following table shows how PROC QLIM interprets values of the ORDER= option.

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	Formatted value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, ORDER=FORMATTED. For the values FORMATTED and INTERNAL, the sort order is machine dependent. For more information about sorting order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide*.

DISTRIBUTION=*distribution-type*

DIST=*distribution-type*

D=*distribution-type*

specifies the cumulative distribution function used to model the response probabilities. Valid values for *distribution-type* are as follows:

NORMAL the normal distribution for the probit model
 LOGISTIC the logistic distribution for the logit model

By default, DISTRIBUTION=NORMAL.

If a multivariate model is specified, logistic distribution is not allowed. Only normal distribution is supported.

Censored Variable Options

CENSORED <(censored-options)>

specifies that the endogenous variables in this statement be censored. Valid *censored-options* are as follows:

LB=*value or variable*

LOWERBOUND=*value or variable*

specifies the lower bound of the censored variables. If *value* is missing or the value in *variable* is missing, no lower bound is set. By default, no lower bound is set.

UB=*value or variable*

UPPERBOUND=*value or variable*

specifies the upper bound of the censored variables. If *value* is missing or the value in *variable* is missing, no upper bound is set. By default, no upper bound is set.

Truncated Variable Options

TRUNCATED <(truncated-options)>

specifies that the endogenous variables in this statement be truncated. Valid *truncated-options* are as follows:

LB=*value or variable*

LOWERBOUND=*value or variable*

specifies the lower bound of the truncated variables. If *value* is missing or the value in *variable* is missing, no lower bound is set. By default, no lower bound is set.

UB=*value or variable*

UPPERBOUND=*value or variable*

specifies the upper bound of the truncated variables. If *value* is missing or the value in *variable* is missing, no upper bound is set. By default, no upper bound is set.

Stochastic Frontier Variable Options

FRONTIER <(frontier-options)>

specifies that the endogenous variable in this statement follow a production or cost frontier. Valid *frontier-options* are as follows:

TYPE=

HALF specifies half-normal model.

EXPONENTIAL specifies exponential model.

TRUNCATED specifies truncated normal model.

PRODUCTION

specifies that the model estimated be a production function.

COST

specifies that the model estimated be a cost function.

If neither PRODUCTION nor COST option is specified, production function is estimated by default.

Selection Options**SELECT** (*select-option*)

specifies selection criteria for sample selection model. *Select-option* specifies the condition for the endogenous variable to be selected. It is written as a variable name, followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a number:

variable operator number

The *variable* is the endogenous variable that the selection is based on. The *operator* can be =, <, >, <=, or >=. Multiple *select-options* can be combined with the logic operators: AND, OR. The following example illustrates the use of the SELECT option:

```
endogenous y1 ~ select (z=0);
endogenous y2 ~ select (z=1 or z=2);
```

The SELECT option can be used together with the DISCRETE, CENSORED, or TRUNCATED option. For example:

```
endogenous y1 ~ select (z=0) discrete;
endogenous y2 ~ select (z=1) censored (lb=0);
endogenous y3 ~ select (z=1 or z=2) truncated (ub=10);
```

For more details about selection models with censoring or truncation, see the section “[Selection Models](#)” on page 1455.

FREQ Statement

FREQ *variable* ;

The FREQ statement identifies a variable that contains the frequency of occurrence of each observation. PROC QLIM treats each observation as if it appears n times, where n is the value of the FREQ variable for the observation. If it is not an integer, the frequency value is truncated to an integer. If the frequency value is less than 1 or missing, the observation is not used in the model fitting. When the FREQ statement is not specified, each observation is assigned a frequency of 1. If you specify more than one FREQ statement, then the first FREQ statement is used.

HETERO Statement

HETERO *dependent variables* ~ *exogenous variables* < / options > ;

The HETERO statement specifies variables that are related to the heteroscedasticity of the residuals and the way these variables are used to model the error variance. The heteroscedastic regression model supported by PROC QLIM is

$$y_i = \mathbf{x}'_i \boldsymbol{\beta} + \epsilon_i$$

$$\epsilon_i \sim N(0, \sigma_i^2)$$

See the section “[Heteroscedasticity](#)” on page 1452 for more details on the specification of functional forms.

LINK=value

The functional form can be specified using the LINK= option. The following option values are allowed:

EXP specifies the exponential link function

$$\sigma_i^2 = \sigma^2(1 + \exp(\mathbf{z}'_i \boldsymbol{\gamma}))$$

LINEAR specifies the linear link function

$$\sigma_i^2 = \sigma^2(1 + \mathbf{z}'_i \boldsymbol{\gamma})$$

When the LINK= option is not specified, the exponential link function is specified by default.

NOCONST

specifies that there be no constant in the linear or exponential heteroscedasticity model.

$$\sigma_i^2 = \sigma^2(\mathbf{z}'_i \boldsymbol{\gamma})$$

$$\sigma_i^2 = \sigma^2 \exp(\mathbf{z}'_i \boldsymbol{\gamma})$$

SQUARE

estimates the model by using the square of linear heteroscedasticity function. For example, you can specify the following heteroscedasticity function:

$$\sigma_i^2 = \sigma^2(1 + (\mathbf{z}'_i \boldsymbol{\gamma})^2)$$

```
model y = x1 x2 / discrete;
hetero y ~ z1 / link=linear square;
```

The option SQUARE does not apply to exponential heteroscedasticity function because the square of an exponential function of $\mathbf{z}'_i \boldsymbol{\gamma}$ is the same as the exponential of $2\mathbf{z}'_i \boldsymbol{\gamma}$. Hence the only difference is that all $\boldsymbol{\gamma}$ estimates are divided by two.

INIT Statement

INIT *initvalue1* < , *initvalue2* . . . > ;

The INIT statement is used to set initial values for parameters in the optimization. Any number of INIT statements can be specified.

Each *initvalue* is written as a parameter or parameter list, followed by an optional equality operator (=), followed by a number:

parameter <=> **number**

MODEL Statement

MODEL *dependent* = *regressors* < / *options* > ;

The MODEL statement specifies the dependent variable and independent regressor variables for the regression model.

The following options can be used in the MODEL statement after a slash (/).

LIMIT1=*value*

specifies the restriction of the threshold value of the first category when the ordinal probit or logit model is estimated. LIMIT1=ZERO is the default option. When LIMIT1=VARYING is specified, the threshold value is estimated.

NOINT

suppresses the intercept parameter.

Endogenous Variable Options

The endogenous variable options are the same as the options specified in the ENDOGENOUS statement. If an endogenous variable has an endogenous option specified in both the MODEL statement and the ENDOGENOUS statement, the option in the ENDOGENOUS statement is used.

BOXCOX Estimation Options

BOXCOX (*option-list*)

specifies options that are used for Box-Cox regression or regressor transformation. For example, the Box-Cox regression is specified as

```
model y = x1 x2 / boxcox(y=lambda, x1 x2)
```

PROC QLIM estimates the following Box-Cox regression model:

$$y_i^{(\lambda)} = \beta_0 + \beta_1 x_{1i}^{(\lambda_2)} + \beta_2 x_{2i}^{(\lambda_2)} + \epsilon_i$$

The *option-list* takes the form *variable-list* <= varname > separated by ','. The *variable-list* specifies that the list of variables have the same Box-Cox transformation; *varname* specifies the name of this Box-Cox coefficient. If *varname* is not specified, the coefficient is called *_Lambdai*, where *i* increments sequentially.

NLOPTIONS Statement

NLOPTIONS < options > ;

PROC QLIM uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. For a list of all the options of the NLOPTIONS statement, see Chapter 6, “Nonlinear Optimization Methods.”

OUTPUT Statement

OUTPUT < OUT=SAS-data-set > < output-options > ;

The OUTPUT statement creates a new SAS data set containing all variables in the input data set and, optionally, the estimates of $\mathbf{x}'\boldsymbol{\beta}$, predicted value, residual, marginal effects, probability, standard deviation of the error, expected value, conditional expected value, technical efficiency measures, and inverse Mills ratio. When the response values are missing for the observation, all output estimates except residual are still computed as long as none of the explanatory variables is missing. This enables you to compute these statistics for prediction. You can specify only one OUTPUT statement.

Details on the specifications in the OUTPUT statement are as follows:

CONDITIONAL

outputs estimates of conditional expected values of continuous endogenous variables.

ERRSTD

outputs estimates of σ_j , the standard deviation of the error term.

EXPECTED

outputs estimates of expected values of continuous endogenous variables.

MARGINAL

outputs marginal effects.

MILLS

outputs estimates of inverse Mills ratios of censored or truncated continuous, binary discrete, and selection endogenous variables.

OUT=SAS-data-set

names the output data set.

PREDICTED

outputs estimates of predicted endogenous variables.

PROB

outputs estimates of probability of discrete endogenous variables taking the current observed responses.

PROBALL

outputs estimates of probability of discrete endogenous variables for all possible responses.

RESIDUAL

outputs estimates of residuals of continuous endogenous variables.

XBETAoutputs estimates of $\mathbf{x}'\boldsymbol{\beta}$.**TE1**

outputs estimates of technical efficiency for each producer in the stochastic frontier model suggested by Battese and Coelli (1988).

TE2

outputs estimates of technical efficiency for each producer in the stochastic frontier model suggested by Jondrow et al. (1982).

RESTRICT Statement

RESTRICT *restriction1* <, *restriction2* ... > ;

The RESTRICT statement is used to impose linear restrictions on the parameter estimates. Any number of RESTRICT statements can be specified, but the number of restrictions imposed is limited by the number of regressors.

Each *restriction* is written as an expression, followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a second expression:

expression operator expression

The *operator* can be =, <, >, <=, or >=. The operator and second expression are optional.

Restriction expressions can be composed of parameter names, multiplication (*), addition (+) and substitution (−) operators, and constants. Parameters named in restriction expressions must be among the parameters estimated by the model. Parameters associated with a regressor variable are referred to by the name of the corresponding regressor variable. The restriction expressions must be a linear function of the parameters.

The following is an example of the use of the RESTRICT statement:

```
proc qlim data=one;
  model y = x1-x10 / discrete;
  restrict x1*2 <= x2 + x3;
run;
```

The RESTRICT statement can also be used to impose cross-equation restrictions in multivariate models. The following RESTRICT statement imposes an equality restriction on coefficients of x_1 in equation y_1 and x_1 in equation y_2 :

```
proc qlim data=one;
  model y1 = x1-x10;
  model y2 = x1-x4;
  endogenous y1 y2 ~ discrete;
  restrict y1.x1=y2.x1;
run;
```

TEST Statement

<'label':> TEST <'string':> equation [,equation...]/ options ;

The TEST statement performs Wald, Lagrange multiplier, and likelihood ratio tests of linear hypotheses about the regression parameters in the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. All hypotheses in one TEST statement are tested jointly. Variable names in the equations must correspond to regressors in the preceding MODEL statement, and each name represents the coefficient of the corresponding regressor. The keyword INTERCEPT refers to the coefficient of the intercept.

The following options can be specified in the TEST statement after the slash (/):

ALL

requests Wald, Lagrange multiplier, and likelihood ratio tests.

WALD

requests the Wald test.

LM

requests the Lagrange multiplier test.

LR

requests the likelihood ratio test.

The following illustrates the use of the TEST statement:

```
proc qlim;
  model y = x1 x2 x3;
  test x1 = 0, x2 * .5 + 2 * x3 = 0;
  test _int: test intercept = 0, x3 = 0;
run;
```

The first test investigates the joint hypothesis that

$$\beta_1 = 0$$

and

$$0.5\beta_2 + 2\beta_3 = 0$$

In case there is more than one MODEL statement in one QLIM procedure, then TEST statement is capable of testing cross equation restrictions. Each parameter reference should be preceded by the name of the dependent variable of the particular model and the dot sign. For example,

```
proc qlim;
  model y1 = x1 x2 x3;
  model y2 = x3 x5 x6;
  test y1.x1 + y2.x6 = 1;
run;
```

This cross equation test investigates the null hypothesis that

$$\beta_{1,1} + \beta_{2,3} = 1$$

in the system of equations

$$\begin{aligned} y_{1,i} &= \alpha_1 + \beta_{1,1}x_{1,i} + \beta_{1,2}x_{2,i} + \beta_{1,3}x_{3,i} \\ y_{2,i} &= \alpha_2 + \beta_{2,1}x_{3,i} + \beta_{2,2}x_{5,i} + \beta_{2,3}x_{6,i}. \end{aligned}$$

Only linear equality restrictions and tests are permitted in PROC QLIM. Tests expressions can be composed only of algebraic operations involving the addition symbol (+), subtraction symbol (-), and multiplication symbol (*).

The TEST statement accepts labels that are reproduced in the printed output. TEST statement can be labeled in two ways. A TEST statement can be preceded by a label followed by a colon. Alternatively, the keyword TEST can be followed by a quoted string. If both are present, PROC QLIM uses the label preceding the colon. In the event no label is present, PROC QLIM automatically labels the tests.

WEIGHT Statement

WEIGHT *variable* *</option>* ;

The WEIGHT statement specifies a variable to supply weighting values to use for each observation in estimating parameters. The log likelihood for each observation is multiplied by the corresponding weight variable value.

If the weight of an observation is nonpositive, that observation is not used in the estimation.

The following option can be added to the WEIGHT statement after a slash (/).

NONORMALIZE

specifies that the weights are required to be used as is. When this option is not specified, the weights are normalized so that they add up to the actual sample size. Weights w_i are normalized by multiplying them by $\frac{n}{\sum_{i=1}^n w_i}$, where n is the sample size.

Details: QLIM Procedure

Ordinal Discrete Choice Modeling

Binary Probit and Logit Model

The binary choice model is

$$y_i^* = \mathbf{x}_i' \boldsymbol{\beta} + \epsilon_i$$

where value of the latent dependent variable, y_i^* , is observed only as follows:

$$\begin{aligned} y_i &= 1 && \text{if } y_i^* > 0 \\ &= 0 && \text{otherwise} \end{aligned}$$

The disturbance, ϵ_i , of the probit model has standard normal distribution with the distribution function (CDF)

$$\Phi(x) = \int_{-\infty}^x \frac{1}{\sqrt{2\pi}} \exp(-t^2/2) dt$$

The disturbance of the logit model has standard logistic distribution with the CDF

$$\Lambda(x) = \frac{\exp(x)}{1 + \exp(x)} = \frac{1}{1 + \exp(-x)}$$

The binary discrete choice model has the following probability that the event $\{y_i = 1\}$ occurs:

$$P(y_i = 1) = F(\mathbf{x}_i' \boldsymbol{\beta}) = \begin{cases} \Phi(\mathbf{x}_i' \boldsymbol{\beta}) & \text{(probit)} \\ \Lambda(\mathbf{x}_i' \boldsymbol{\beta}) & \text{(logit)} \end{cases}$$

The log-likelihood function is

$$\ell = \sum_{i=1}^N \{y_i \log[F(\mathbf{x}_i' \boldsymbol{\beta})] + (1 - y_i) \log[1 - F(\mathbf{x}_i' \boldsymbol{\beta})]\}$$

where the CDF $F(x)$ is defined as $\Phi(x)$ for the probit model while $F(x) = \Lambda(x)$ for logit. The first order derivative of the logit model are

$$\frac{\partial \ell}{\partial \boldsymbol{\beta}} = \sum_{i=1}^N (y_i - \Lambda(\mathbf{x}_i' \boldsymbol{\beta})) \mathbf{x}_i$$

The probit model has more complicated derivatives

$$\frac{\partial \ell}{\partial \boldsymbol{\beta}} = \sum_{i=1}^N \left[\frac{(2y_i - 1)\phi(\mathbf{x}'_i \boldsymbol{\beta})}{\Phi(\mathbf{x}'_i \boldsymbol{\beta})} \right] \mathbf{x}_i = \sum_{i=1}^N r_i \mathbf{x}_i$$

where

$$r_i = \frac{(2y_i - 1)\phi(\mathbf{x}'_i \boldsymbol{\beta})}{\Phi(\mathbf{x}'_i \boldsymbol{\beta})}$$

Note that the logit maximum likelihood estimates are $\frac{\pi}{\sqrt{3}}$ times greater than probit maximum likelihood estimates, since the probit parameter estimates, $\boldsymbol{\beta}$, are standardized, and the error term with logistic distribution has a variance of $\frac{\pi^2}{3}$.

Ordinal Probit/Logit

When the dependent variable is observed in sequence with M categories, binary discrete choice modeling is not appropriate for data analysis. McKelvey and Zavoina (1975) proposed the ordinal (or ordered) probit model.

Consider the following regression equation:

$$y_i^* = \mathbf{x}'_i \boldsymbol{\beta} + \epsilon_i$$

where error disturbances, ϵ_i , have the distribution function F . The unobserved continuous random variable, y_i^* , is identified as M categories. Suppose there are $M + 1$ real numbers, μ_0, \dots, μ_M , where $\mu_0 = -\infty$, $\mu_1 = 0$, $\mu_M = \infty$, and $\mu_0 \leq \mu_1 \leq \dots \leq \mu_M$. Define

$$R_{i,j} = \mu_j - \mathbf{x}'_i \boldsymbol{\beta}$$

The probability that the unobserved dependent variable is contained in the j th category can be written as

$$P[\mu_{j-1} < y_i^* \leq \mu_j] = F(R_{i,j}) - F(R_{i,j-1})$$

The log-likelihood function is

$$\ell = \sum_{i=1}^N \sum_{j=1}^M d_{ij} \log [F(R_{i,j}) - F(R_{i,j-1})]$$

where

$$d_{ij} = \begin{cases} 1 & \text{if } \mu_{j-1} < y_i \leq \mu_j \\ 0 & \text{otherwise} \end{cases}$$

The first derivatives are written as

$$\frac{\partial \ell}{\partial \boldsymbol{\beta}} = \sum_{i=1}^N \sum_{j=1}^M d_{ij} \left[\frac{f(R_{i,j-1}) - f(R_{i,j})}{F(R_{i,j}) - F(R_{i,j-1})} \mathbf{x}_i \right]$$

$$\frac{\partial \ell}{\partial \mu_k} = \sum_{i=1}^N \sum_{j=1}^M d_{ij} \left[\frac{\delta_{j,k} f(R_{i,j}) - \delta_{j-1,k} f(R_{i,j-1})}{F(R_{i,j}) - F(R_{i,j-1})} \right]$$

where $f(x) = \frac{dF(x)}{dx}$ and $\delta_{j,k} = 1$ if $j = k$. When the ordinal probit is estimated, it is assumed that $F(R_{i,j}) = \Phi(R_{i,j})$. The ordinal logit model is estimated if $F(R_{i,j}) = \Lambda(R_{i,j})$. The first threshold parameter, μ_1 , is estimated when the LIMIT1=VARYING option is specified. By default (LIMIT1=ZERO), so that $M - 2$ threshold parameters (μ_2, \dots, μ_{M-1}) are estimated.

The ordered probit models are analyzed by Aitchison and Silvey (1957), and Cox (1970) discussed ordered response data by using the logit model. They defined the probability that y_i^* belongs to j th category as

$$P[\mu_{j-1} < y_i \leq \mu_j] = F(\mu_j + \mathbf{x}'_i \boldsymbol{\theta}) - F(\mu_{j-1} + \mathbf{x}'_i \boldsymbol{\theta})$$

where $\mu_0 = -\infty$ and $\mu_M = \infty$. Therefore, the ordered response model analyzed by Aitchison and Silvey can be estimated if the LIMIT1=VARYING option is specified. Note that $\boldsymbol{\theta} = -\boldsymbol{\beta}$.

Goodness-of-Fit Measures

The goodness-of-fit measures discussed in this section apply only to discrete dependent variable models.

McFadden (1974) suggested a likelihood ratio index that is analogous to the R^2 in the linear regression model:

$$R_M^2 = 1 - \frac{\ln L}{\ln L_0}$$

where L is the value of the maximum likelihood function and L_0 is a likelihood function when regression coefficients except an intercept term are zero. It can be shown that L_0 can be written as

$$L_0 = \sum_{j=1}^M N_j \ln\left(\frac{N_j}{N}\right)$$

where N_j is the number of responses in category j .

Estrella (1998) proposes the following requirements for a goodness-of-fit measure to be desirable in discrete choice modeling:

- The measure must take values in $[0, 1]$, where 0 represents no fit and 1 corresponds to perfect fit.
- The measure should be directly related to the valid test statistic for significance of all slope coefficients.
- The derivative of the measure with respect to the test statistic should comply with corresponding derivatives in a linear regression.

Estrella's (1998) measure is written

$$R_{E1}^2 = 1 - \left(\frac{\ln L}{\ln L_0} \right)^{-\frac{2}{N} \ln L_0}$$

An alternative measure suggested by Estrella (1998) is

$$R_{E2}^2 = 1 - [(\ln L - K) / \ln L_0]^{-\frac{2}{N} \ln L_0}$$

where $\ln L_0$ is computed with null slope parameter values, N is the number observations used, and K represents the number of estimated parameters.

Other goodness-of-fit measures are summarized as follows:

$$R_{CU1}^2 = 1 - \left(\frac{L_0}{L} \right)^{\frac{2}{N}} \quad (\text{Cragg - Uhler1})$$

$$R_{CU2}^2 = \frac{1 - (L_0/L)^{\frac{2}{N}}}{1 - L_0^{\frac{2}{N}}} \quad (\text{Cragg - Uhler2})$$

$$R_A^2 = \frac{2(\ln L - \ln L_0)}{2(\ln L - \ln L_0) + N} \quad (\text{Aldrich - Nelson})$$

$$R_{VZ}^2 = R_A^2 \frac{2 \ln L_0 - N}{2 \ln L_0} \quad (\text{Veall - Zimmermann})$$

$$R_{MZ}^2 = \frac{\sum_{i=1}^N (\hat{y}_i - \bar{\hat{y}})^2}{N + \sum_{i=1}^N (\hat{y}_i - \bar{\hat{y}})^2} \quad (\text{McKelvey - Zavoina})$$

where $\hat{y}_i = \mathbf{x}_i' \hat{\boldsymbol{\beta}}$ and $\bar{\hat{y}} = \sum_{i=1}^N \hat{y}_i / N$.

Limited Dependent Variable Models

Censored Regression Models

When the dependent variable is censored, values in a certain range are all transformed to a single value. For example, the standard tobit model can be defined as

$$y_i^* = \mathbf{x}_i' \boldsymbol{\beta} + \epsilon_i$$

$$y_i = \begin{cases} y_i^* & \text{if } y_i^* > 0 \\ 0 & \text{if } y_i^* \leq 0 \end{cases}$$

where $\epsilon_i \sim iidN(0, \sigma^2)$. The log-likelihood function of the standard censored regression model is

$$\ell = \sum_{i \in \{y_i=0\}} \ln[1 - \Phi(\mathbf{x}_i' \boldsymbol{\beta} / \sigma)] + \sum_{i \in \{y_i>0\}} \ln \left[\phi \left(\frac{y_i - \mathbf{x}_i' \boldsymbol{\beta}}{\sigma} \right) / \sigma \right]$$

where $\Phi(\cdot)$ is the cumulative density function of the standard normal distribution and $\phi(\cdot)$ is the probability density function of the standard normal distribution.

The tobit model can be generalized to handle observation-by-observation censoring. The censored model on both of the lower and upper limits can be defined as

$$y_i = \begin{cases} R_i & \text{if } y_i^* \geq R_i \\ y_i^* & \text{if } L_i < y_i^* < R_i \\ L_i & \text{if } y_i^* \leq L_i \end{cases}$$

The log-likelihood function can be written as

$$\begin{aligned} \ell = & \sum_{i \in \{L_i < y_i < R_i\}} \ln \left[\phi \left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) / \sigma \right] + \sum_{i \in \{y_i = R_i\}} \ln \left[\Phi \left(-\frac{R_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) \right] + \\ & \sum_{i \in \{y_i = L_i\}} \ln \left[\Phi \left(\frac{L_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) \right] \end{aligned}$$

Log-likelihood functions of the lower- or upper-limit censored model are easily derived from the two-limit censored model. The log-likelihood function of the lower-limit censored model is

$$\ell = \sum_{i \in \{y_i > L_i\}} \ln \left[\phi \left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) / \sigma \right] + \sum_{i \in \{y_i = L_i\}} \ln \left[\Phi \left(\frac{L_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) \right]$$

The log-likelihood function of the upper-limit censored model is

$$\ell = \sum_{i \in \{y_i < R_i\}} \ln \left[\phi \left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) / \sigma \right] + \sum_{i \in \{y_i = R_i\}} \ln \left[1 - \Phi \left(\frac{R_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) \right]$$

Types of Tobit Models

Amemiya (1984) classified Tobit models into five types based on characteristics of the likelihood function. For notational convenience, let P denote a distribution or density function, y_{ji}^* is assumed to be normally distributed with mean $\mathbf{x}'_{ji} \boldsymbol{\beta}_j$ and variance σ_j^2 .

Type 1 Tobit

The Type 1 Tobit model was already discussed in the preceding section.

$$\begin{aligned} y_{1i}^* &= \mathbf{x}'_{1i} \boldsymbol{\beta}_1 + u_{1i} \\ y_{1i} &= y_{1i}^* \quad \text{if } y_{1i}^* > 0 \\ &= 0 \quad \text{if } y_{1i}^* \leq 0 \end{aligned}$$

The likelihood function is characterized as $P(y_1 < 0)P(y_1)$.

Type 2 Tobit

The Type 2 Tobit model is defined as

$$\begin{aligned}
 y_{1i}^* &= \mathbf{x}'_{1i} \boldsymbol{\beta}_1 + u_{1i} \\
 y_{2i}^* &= \mathbf{x}'_{2i} \boldsymbol{\beta}_2 + u_{2i} \\
 y_{1i} &= 1 \text{ if } y_{1i}^* > 0 \\
 &= 0 \text{ if } y_{1i}^* \leq 0 \\
 y_{2i} &= y_{2i}^* \text{ if } y_{1i}^* > 0 \\
 &= 0 \text{ if } y_{1i}^* \leq 0
 \end{aligned}$$

where $(u_{1i}, u_{2i}) \sim N(0, \Sigma)$. The likelihood function is described as $P(y_1 < 0)P(y_1 > 0, y_2)$.

Type 3 Tobit

The Type 3 Tobit model is different from the Type 2 Tobit in that y_{1i}^* of the Type 3 Tobit is observed when $y_{1i}^* > 0$.

$$\begin{aligned}
 y_{1i}^* &= \mathbf{x}'_{1i} \boldsymbol{\beta}_1 + u_{1i} \\
 y_{2i}^* &= \mathbf{x}'_{2i} \boldsymbol{\beta}_2 + u_{2i} \\
 y_{1i} &= y_{1i}^* \text{ if } y_{1i}^* > 0 \\
 &= 0 \text{ if } y_{1i}^* \leq 0 \\
 y_{2i} &= y_{2i}^* \text{ if } y_{1i}^* > 0 \\
 &= 0 \text{ if } y_{1i}^* \leq 0
 \end{aligned}$$

where $(u_{1i}, u_{2i})' \sim iidN(0, \Sigma)$.

The likelihood function is characterized as $P(y_1 < 0)P(y_1, y_2)$.

Type 4 Tobit

The Type 4 Tobit model consists of three equations:

$$\begin{aligned}
 y_{1i}^* &= \mathbf{x}'_{1i} \boldsymbol{\beta}_1 + u_{1i} \\
 y_{2i}^* &= \mathbf{x}'_{2i} \boldsymbol{\beta}_2 + u_{2i} \\
 y_{3i}^* &= \mathbf{x}'_{3i} \boldsymbol{\beta}_3 + u_{3i} \\
 y_{1i} &= y_{1i}^* \text{ if } y_{1i}^* > 0 \\
 &= 0 \text{ if } y_{1i}^* \leq 0 \\
 y_{2i} &= y_{2i}^* \text{ if } y_{1i}^* > 0 \\
 &= 0 \text{ if } y_{1i}^* \leq 0 \\
 y_{3i} &= y_{3i}^* \text{ if } y_{1i}^* \leq 0 \\
 &= 0 \text{ if } y_{1i}^* > 0
 \end{aligned}$$

where $(u_{1i}, u_{2i}, u_{3i})' \sim iidN(0, \Sigma)$. The likelihood function of the Type 4 Tobit model is characterized as $P(y_1 < 0, y_3)P(y_1, y_2)$.

Type 5 Tobit

The Type 5 Tobit model is defined as follows:

$$\begin{aligned}
 y_{1i}^* &= \mathbf{x}'_{1i} \boldsymbol{\beta}_1 + u_{1i} \\
 y_{2i}^* &= \mathbf{x}'_{2i} \boldsymbol{\beta}_2 + u_{2i} \\
 y_{3i}^* &= \mathbf{x}'_{3i} \boldsymbol{\beta}_3 + u_{3i} \\
 y_{1i} &= 1 \text{ if } y_{1i}^* > 0 \\
 &= 0 \text{ if } y_{1i}^* \leq 0 \\
 y_{2i} &= y_{2i}^* \text{ if } y_{1i}^* > 0 \\
 &= 0 \text{ if } y_{1i}^* \leq 0 \\
 y_{3i} &= y_{3i}^* \text{ if } y_{1i}^* \leq 0 \\
 &= 0 \text{ if } y_{1i}^* > 0
 \end{aligned}$$

where $(u_{1i}, u_{2i}, u_{3i})'$ are from *iid* trivariate normal distribution. The likelihood function of the Type 5 Tobit model is characterized as $P(y_1 < 0, y_3)P(y_1 > 0, y_2)$.

Code examples for these models can be found in “[Example 21.6: Types of Tobit Models](#)” on page 1476.

Truncated Regression Models

In a truncated model, the observed sample is a subset of the population where the dependent variable falls in a certain range. For example, when neither a dependent variable nor exogenous variables are observed for $y_i^* \leq 0$, the truncated regression model can be specified.

$$\ell = \sum_{i \in \{y_i > 0\}} \left\{ -\ln \Phi(\mathbf{x}'_i \boldsymbol{\beta} / \sigma) + \ln \left[\frac{\phi((y_i - \mathbf{x}'_i \boldsymbol{\beta}) / \sigma)}{\sigma} \right] \right\}$$

Two-limit truncation model is defined as

$$y_i = y_i^* \text{ if } L_i < y_i^* < R_i$$

The log-likelihood function of the two-limit truncated regression model is

$$\ell = \sum_{i=1}^N \left\{ \ln \left[\phi\left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) / \sigma \right] - \ln \left[\Phi\left(\frac{R_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) - \Phi\left(\frac{L_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) \right] \right\}$$

The log-likelihood functions of the lower- and upper-limit truncation model are

$$\ell = \sum_{i=1}^N \left\{ \ln \left[\phi\left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) / \sigma \right] - \ln \left[1 - \Phi\left(\frac{L_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) \right] \right\} \quad (\text{lower})$$

$$\ell = \sum_{i=1}^N \left\{ \ln \left[\phi\left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) / \sigma \right] - \ln \left[\Phi\left(\frac{R_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) \right] \right\} \quad (\text{upper})$$

Stochastic Frontier Production and Cost Models

Stochastic frontier production models were first developed by Aigner, Lovell, and Schmidt (1977) and Meeusen and van den Broeck (1977). Specification of these models allow for random shocks of the production or cost but also include a term for technological or cost inefficiency. Assuming that the production function takes a log-linear Cobb-Douglas form, the stochastic frontier production model can be written as

$$\ln(y_i) = \beta_0 + \sum_n \beta_n \ln(x_{ni}) + \epsilon_i$$

where $\epsilon_i = v_i - u_i$. The v_i term represents the stochastic error component and u_i is the nonnegative, technology inefficiency error component. The v_i error component is assumed to be distributed iid normal and independently from u_i . If $u_i > 0$, the error term, ϵ_i , is negatively skewed and represents technology inefficiency. If $u_i < 0$, the error term ϵ_i is positively skewed and represents cost inefficiency. PROC QLIM models the u_i error component as a half normal, exponential, or truncated normal distribution.

The Normal-Half Normal Model

In case of the normal-half normal model, v_i is iid $N(0, \sigma_v^2)$, u_i is iid $N^+(0, \sigma_u^2)$ with v_i and u_i independent of each other. Given the independence of error terms, the joint density of v and u can be written as

$$f(u, v) = \frac{2}{2\pi\sigma_u\sigma_v} \exp\left\{-\frac{u^2}{2\sigma_u^2} - \frac{v^2}{2\sigma_v^2}\right\}$$

Substituting $v = \epsilon + u$ into the preceding equation gives

$$f(u, \epsilon) = \frac{2}{2\pi\sigma_u\sigma_v} \exp\left\{-\frac{u^2}{2\sigma_u^2} - \frac{(\epsilon + u)^2}{2\sigma_v^2}\right\}$$

Integrating u out to obtain the marginal density function of ϵ results in the following form:

$$\begin{aligned} f(\epsilon) &= \int_0^{\infty} f(u, \epsilon) du \\ &= \frac{2}{\sqrt{2\pi}\sigma} \left[1 - \Phi\left(\frac{\epsilon\lambda}{\sigma}\right)\right] \exp\left\{-\frac{\epsilon^2}{2\sigma^2}\right\} \\ &= \frac{2}{\sigma} \phi\left(\frac{\epsilon}{\sigma}\right) \Phi\left(-\frac{\epsilon\lambda}{\sigma}\right) \end{aligned}$$

where $\lambda = \sigma_u/\sigma_v$ and $\sigma = \sqrt{\sigma_u^2 + \sigma_v^2}$.

In the case of a stochastic frontier cost model, $v = \epsilon - u$ and

$$f(\epsilon) = \frac{2}{\sigma} \phi\left(\frac{\epsilon}{\sigma}\right) \Phi\left(\frac{\epsilon\lambda}{\sigma}\right)$$

The log-likelihood function for the production model with N producers is written as

$$\ln L = \text{constant} - N \ln \sigma + \sum_i \ln \Phi \left(-\frac{\epsilon_i \lambda}{\sigma} \right) - \frac{1}{2\sigma^2} \sum_i \epsilon_i^2$$

The Normal-Exponential Model

Under the normal-exponential model, v_i is iid $N(0, \sigma_v^2)$ and u_i is iid exponential. Given the independence of error term components u_i and v_i , the joint density of v and u can be written as

$$f(u, v) = \frac{1}{\sqrt{2\pi} \sigma_u \sigma_v} \exp \left\{ -\frac{u}{\sigma_u} - \frac{v^2}{2\sigma_v^2} \right\}$$

The marginal density function of ϵ for the production function is

$$\begin{aligned} f(\epsilon) &= \int_0^\infty f(u, \epsilon) du \\ &= \left(\frac{1}{\sigma_u} \right) \Phi \left(-\frac{\epsilon}{\sigma_v} - \frac{\sigma_v}{\sigma_u} \right) \exp \left\{ \frac{\epsilon}{\sigma_u} + \frac{\sigma_v^2}{2\sigma_u^2} \right\} \end{aligned}$$

and the marginal density function for the cost function is equal to

$$f(\epsilon) = \left(\frac{1}{\sigma_u} \right) \Phi \left(\frac{\epsilon}{\sigma_v} - \frac{\sigma_v}{\sigma_u} \right) \exp \left\{ -\frac{\epsilon}{\sigma_u} + \frac{\sigma_v^2}{2\sigma_u^2} \right\}$$

The log-likelihood function for the normal-exponential production model with N producers is

$$\ln L = \text{constant} - N \ln \sigma_u + N \left(\frac{\sigma_v^2}{2\sigma_u^2} \right) + \sum_i \frac{\epsilon_i}{\sigma_u} + \sum_i \ln \Phi \left(\frac{\epsilon_i}{\sigma_v} - \frac{\sigma_v}{\sigma_u} \right)$$

The Normal-Truncated Normal Model

The normal-truncated normal model is a generalization of the normal-half normal model by allowing the mean of u_i to differ from zero. Under the normal-truncated normal model, the error term component v_i is iid $N^+(0, \sigma_v^2)$ and u_i is iid $N(\mu, \sigma_u^2)$. The joint density of v_i and u_i can be written as

$$f(u, v) = \frac{1}{\sqrt{2\pi}\sigma_u\sigma_v\Phi(\mu/\sigma_u)} \exp\left\{-\frac{(u-\mu)^2}{2\sigma_u^2} - \frac{v^2}{2\sigma_v^2}\right\}$$

The marginal density function of ϵ for the production function is

$$\begin{aligned} f(\epsilon) &= \int_0^\infty f(u, \epsilon) du \\ &= \frac{1}{\sqrt{2\pi}\sigma\Phi(\mu/\sigma_u)} \Phi\left(\frac{\mu}{\sigma\lambda} - \frac{\epsilon\lambda}{\sigma}\right) \exp\left\{-\frac{(\epsilon+\mu)^2}{2\sigma^2}\right\} \\ &= \frac{1}{\sigma} \phi\left(\frac{\epsilon+\mu}{\sigma}\right) \Phi\left(\frac{\mu}{\sigma\lambda} - \frac{\epsilon\lambda}{\sigma}\right) \left[\Phi\left(\frac{\mu}{\sigma_u}\right)\right]^{-1} \end{aligned}$$

and the marginal density function for the cost function is

$$f(\epsilon) = \frac{1}{\sigma} \phi\left(\frac{\epsilon-\mu}{\sigma}\right) \Phi\left(\frac{\mu}{\sigma\lambda} + \frac{\epsilon\lambda}{\sigma}\right) \left[\Phi\left(\frac{\mu}{\sigma_u}\right)\right]^{-1}$$

The log-likelihood function for the normal-truncated normal production model with N producers is

$$\begin{aligned} \ln L &= \text{constant} - N \ln \sigma - N \ln \Phi\left(\frac{\mu}{\sigma_u}\right) + \sum_i \ln \Phi\left(\frac{\mu}{\sigma\lambda} + \frac{\epsilon_i \lambda}{\sigma}\right) \\ &\quad - \frac{1}{2} \sum_i \left(\frac{\epsilon_i + \mu}{\sigma}\right)^2 \end{aligned}$$

For more detail on normal-half normal, normal-exponential, and normal-truncated models, see Kumbhakar and Knox Lovell (2000) and Coelli, Prasada Rao, and Battese (1998).

Heteroscedasticity and Box-Cox Transformation

Heteroscedasticity

If the variance of regression disturbance, (ϵ_i) , is heteroscedastic, the variance can be specified as a function of variables

$$E(\epsilon_i^2) = \sigma_i^2 = f(\mathbf{z}'_i \boldsymbol{\gamma})$$

The following table shows various functional forms of heteroscedasticity and the corresponding options to request each model.

No.	Model	Options
1	$f(\mathbf{z}'_i \boldsymbol{\gamma}) = \sigma^2(1 + \exp(\mathbf{z}'_i \boldsymbol{\gamma}))$	LINK=EXP (default)
2	$f(\mathbf{z}'_i \boldsymbol{\gamma}) = \sigma^2 \exp(\mathbf{z}'_i \boldsymbol{\gamma})$	LINK=EXP NOCONST
3	$f(\mathbf{z}'_i \boldsymbol{\gamma}) = \sigma^2(1 + \sum_{l=1}^L \gamma_l z_{li})$	LINK=LINEAR
4	$f(\mathbf{z}'_i \boldsymbol{\gamma}) = \sigma^2(1 + (\sum_{l=1}^L \gamma_l z_{li})^2)$	LINK=LINEAR SQUARE
5	$f(\mathbf{z}'_i \boldsymbol{\gamma}) = \sigma^2(\sum_{l=1}^L \gamma_l z_{li})$	LINK=LINEAR NOCONST
6	$f(\mathbf{z}'_i \boldsymbol{\gamma}) = \sigma^2((\sum_{l=1}^L \gamma_l z_{li})^2)$	LINK=LINEAR SQUARE NOCONST

For discrete choice models, σ^2 is normalized ($\sigma^2 = 1$) since this parameter is not identified. Note that in models 3 and 5, it may be possible that variances of some observations are negative. Although the QLIM procedure assigns a large penalty to move the optimization away from such region, it is possible that the optimization cannot improve the objective function value and gets locked in the region. Signs of such outcome include extremely small likelihood values or missing standard errors in the estimates. In models 2 and 6, variances are guaranteed to be greater or equal to zero, but it may be possible that variances of some observations are very close to zero. In these scenarios, standard errors may be missing. Models 1 and 4 do not have such problems. Variances in these models are always positive and never close to zero.

The heteroscedastic regression model is estimated using the following log-likelihood function:

$$\ell = -\frac{N}{2} \ln(2\pi) - \sum_{i=1}^N \frac{1}{2} \ln(\sigma_i^2) - \frac{1}{2} \sum_{i=1}^N \left(\frac{e_i}{\sigma_i}\right)^2$$

where $e_i = y_i - \mathbf{x}'_i \boldsymbol{\beta}$.

Box-Cox Modeling

The Box-Cox transformation on x is defined as

$$x^{(\lambda)} = \begin{cases} \frac{x^\lambda - 1}{\lambda} & \text{if } \lambda \neq 0 \\ \ln(x) & \text{if } \lambda = 0 \end{cases}$$

The Box-Cox regression model with heteroscedasticity is written as

$$\begin{aligned} y_i^{(\lambda_0)} &= \beta_0 + \sum_{k=1}^K \beta_k x_{ki}^{(\lambda_k)} + \epsilon_i \\ &= \mu_i + \epsilon_i \end{aligned}$$

where $\epsilon_i \sim N(0, \sigma_i^2)$ and transformed variables must be positive. In practice, too many transformation parameters cause numerical problems in model fitting. It is common to have the same Box-Cox transformation performed on all the variables — that is, $\lambda_0 = \lambda_1 = \dots = \lambda_K$. It is required for the

magnitude of transformed variables to be in the tolerable range if the corresponding transformation parameters are $|\lambda| > 1$.

The log-likelihood function of the Box-Cox regression model is written as

$$\ell = -\frac{N}{2} \ln(2\pi) - \sum_{i=1}^N \ln(\sigma_i) - \frac{1}{2\sigma_i^2} \sum_{i=1}^N e_i^2 + (\lambda_0 - 1) \sum_{i=1}^N \ln(y_i)$$

where $e_i = y_i^{(\lambda_0)} - \mu_i$.

When the dependent variable is discrete, censored, or truncated, the Box-Cox transformation can be applied only to explanatory variables.

Bivariate Limited Dependent Variable Modeling

The generic form of a bivariate limited dependent variable model is

$$\begin{aligned} y_{1i}^* &= \mathbf{x}'_{1i} \boldsymbol{\beta}_1 + \epsilon_{1i} \\ y_{2i}^* &= \mathbf{x}'_{2i} \boldsymbol{\beta}_2 + \epsilon_{2i} \end{aligned}$$

where the disturbances, ϵ_{1i} and ϵ_{2i} , have joint normal distribution with zero mean, standard deviations σ_1 and σ_2 , and correlation of ρ . y_1^* and y_2^* are latent variables. The dependent variables y_1 and y_2 are observed if the latent variables y_1^* and y_2^* fall in certain ranges:

$$\begin{aligned} y_1 &= y_{1i} \text{ if } y_{1i}^* \in D_1(y_{1i}) \\ y_2 &= y_{2i} \text{ if } y_{2i}^* \in D_2(y_{2i}) \end{aligned}$$

D is a transformation from (y_{1i}^*, y_{2i}^*) to (y_{1i}, y_{2i}) . For example, if y_1 and y_2 are censored variables with lower bound 0, then

$$\begin{aligned} y_1 &= y_{1i} \text{ if } y_{1i}^* > 0, & y_1 &= 0 \text{ if } y_{1i}^* \leq 0 \\ y_2 &= y_{2i} \text{ if } y_{2i}^* > 0, & y_2 &= 0 \text{ if } y_{2i}^* \leq 0 \end{aligned}$$

There are three cases for the log likelihood of (y_{1i}, y_{2i}) . The first case is that $y_{1i} = y_{1i}^*$ and $y_{2i} = y_{2i}^*$. That is, this observation is mapped to one point in the space of latent variables. The log likelihood is computed from a bivariate normal density,

$$\ell_i = \ln \left[\phi_2 \left(\frac{y_1 - \mathbf{x}_1' \boldsymbol{\beta}_1}{\sigma_1}, \frac{y_2 - \mathbf{x}_2' \boldsymbol{\beta}_2}{\sigma_2}, \rho \right) \right] - \ln \sigma_1 - \ln \sigma_2$$

where $\phi_2(u, v, \rho)$ is the density function for standardized bivariate normal distribution with correlation ρ ,

$$\phi_2(u, v, \rho) = \frac{e^{-(1/2)(u^2 + v^2 - 2\rho uv)/(1 - \rho^2)}}{2\pi(1 - \rho^2)^{1/2}}$$

The second case is that one observed dependent variable is mapped to a point of its latent variable and the other dependent variable is mapped to a segment in the space of its latent variable. For example, in the bivariate censored model specified, if observed $y_1 > 0$ and $y_2 = 0$, then $y_1^* = y_1$ and $y_2^* \in (-\infty, 0]$. In general, the log likelihood for one observation can be written as follows (the subscript i is dropped for simplicity): If one set is a single point and the other set is a range, without loss of generality, let $D_1(y_1) = \{y_1\}$ and $D_2(y_2) = [L_2, R_2]$,

$$\begin{aligned} \ell_i &= \ln \left[\phi \left(\frac{y_1 - \mathbf{x}_1' \boldsymbol{\beta}_1}{\sigma_1} \right) \right] - \ln \sigma_1 \\ &+ \ln \left[\Phi \left(\frac{R_2 - \mathbf{x}_2' \boldsymbol{\beta}_2 - \rho \frac{y_1 - \mathbf{x}_1' \boldsymbol{\beta}_1}{\sigma_1}}{\sigma_2} \right) - \Phi \left(\frac{L_2 - \mathbf{x}_2' \boldsymbol{\beta}_2 - \rho \frac{y_1 - \mathbf{x}_1' \boldsymbol{\beta}_1}{\sigma_1}}{\sigma_2} \right) \right] \end{aligned}$$

where ϕ and Φ are the density function and the cumulative probability function for standardized univariate normal distribution.

The third case is that both dependent variables are mapped to segments in the space of latent variables. For example, in the bivariate censored model specified, if observed $y_1 = 0$ and $y_2 = 0$, then $y_1^* \in (-\infty, 0]$ and $y_2^* \in (-\infty, 0]$. In general, if $D_1(y_1) = [L_1, R_1]$ and $D_2(y_2) = [L_2, R_2]$, the log likelihood is

$$\ell_i = \ln \int_{\frac{L_1 - \mathbf{x}_1' \boldsymbol{\beta}_1}{\sigma_1}}^{\frac{R_1 - \mathbf{x}_1' \boldsymbol{\beta}_1}{\sigma_1}} \int_{\frac{L_2 - \mathbf{x}_2' \boldsymbol{\beta}_2}{\sigma_2}}^{\frac{R_2 - \mathbf{x}_2' \boldsymbol{\beta}_2}{\sigma_2}} \phi_2(u, v, \rho) du dv$$

Selection Models

In sample selection models, one or several dependent variables are observed when another variable takes certain values. For example, the standard Heckman selection model can be defined as

$$\begin{aligned} z_i^* &= \mathbf{w}_i' \boldsymbol{\gamma} + u_i \\ z_i &= \begin{cases} 1 & \text{if } z_i^* > 0 \\ 0 & \text{if } z_i^* \leq 0 \end{cases} \\ y_i &= \mathbf{x}_i' \boldsymbol{\beta} + \epsilon_i \quad \text{if } z_i = 1 \end{aligned}$$

where u_i and ϵ_i are jointly normal with zero mean, standard deviations of 1 and σ , and correlation of ρ . z is the variable that the selection is based on, and y is observed when z has a value of 1. Least squares regression using the observed data of y produces inconsistent estimates of $\boldsymbol{\beta}$. Maximum likelihood method is used to estimate selection models. It is also possible to estimate these models by using Heckman's method, which is more computationally efficient. But it can be shown that the resulting estimates, although consistent, are not asymptotically efficient under normality assumption. Moreover, this method often violates the constraint on correlation coefficient $|\rho| \leq 1$.

The log-likelihood function of the Heckman selection model is written as

$$\begin{aligned} \ell &= \sum_{i \in \{z_i=0\}} \ln[1 - \Phi(\mathbf{w}'_i \boldsymbol{\gamma})] \\ &+ \sum_{i \in \{z_i=1\}} \left\{ \ln \phi\left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}\right) - \ln \sigma + \ln \Phi\left(\frac{\mathbf{w}'_i \boldsymbol{\gamma} + \rho \frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}}{\sqrt{1 - \rho^2}}\right) \right\} \end{aligned}$$

Only one variable is allowed for the selection to be based on, but the selection may lead to several variables. For example, in the following switching regression model,

$$\begin{aligned} z_i^* &= \mathbf{w}'_i \boldsymbol{\gamma} + u_i \\ z_i &= \begin{cases} 1 & \text{if } z_i^* > 0 \\ 0 & \text{if } z_i^* \leq 0 \end{cases} \end{aligned}$$

$$\begin{aligned} y_{1i} &= \mathbf{x}'_{1i} \boldsymbol{\beta}_1 + \epsilon_{1i} & \text{if } z_i = 0 \\ y_{2i} &= \mathbf{x}'_{2i} \boldsymbol{\beta}_2 + \epsilon_{2i} & \text{if } z_i = 1 \end{aligned}$$

z is the variable that the selection is based on. If $z = 0$, then y_1 is observed. If $z = 1$, then y_2 is observed. Because it is never the case that y_1 and y_2 are observed at the same time, the correlation between y_1 and y_2 cannot be estimated. Only the correlation between z and y_1 and the correlation between z and y_2 can be estimated. This estimation uses the maximum likelihood method.

A brief example of the code for this model can be found in “[Example 21.4: Sample Selection Model](#)” on page 1472.

The Heckman selection model can include censoring or truncation. For a brief example of the code for these models see “[Example 21.5: Sample Selection Model with Truncation and Censoring](#)” on page 1473. The following example shows a variable y_i that is censored from below at zero.

$$\begin{aligned} z_i^* &= \mathbf{w}'_i \boldsymbol{\gamma} + u_i \\ z_i &= \begin{cases} 1 & \text{if } z_i^* > 0 \\ 0 & \text{if } z_i^* \leq 0 \end{cases} \\ y_i^* &= \mathbf{x}'_i \boldsymbol{\beta} + \epsilon_i & \text{if } z_i = 1 \\ y_i &= \begin{cases} y_i^* & \text{if } y_i^* > 0 \\ 0 & \text{if } y_i^* \leq 0 \end{cases} \end{aligned}$$

In this case, the log-likelihood function of the Heckman selection model needs to be modified to include the censored region.

$$\begin{aligned} \ell &= \sum_{\{i|z_i=0\}} \ln[1 - \Phi(\mathbf{w}'_i \boldsymbol{\gamma})] \\ &+ \sum_{\{i|z_i=1, y_i=y_i^*\}} \left\{ \ln \left[\phi \left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) \right] - \ln \sigma + \ln \left[\Phi \left(\frac{\mathbf{w}'_i \boldsymbol{\gamma} + \rho \frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}}{\sqrt{1 - \rho^2}} \right) \right] \right\} \\ &+ \sum_{\{i|z_i=1, y_i=0\}} \ln \int_{-\infty}^{-\frac{\mathbf{x}'_i \boldsymbol{\beta}}{\sigma}} \int_{-\mathbf{w}'_i \boldsymbol{\gamma}}^{\infty} \phi_2(u, v, \rho) du dv \end{aligned}$$

In case y_i is truncated from below at zero instead of censored, the likelihood function can be written as

$$\begin{aligned} \ell &= \sum_{\{i|z_i=0\}} \ln[1 - \Phi(\mathbf{w}'_i \boldsymbol{\gamma})] \\ &+ \sum_{\{i|z_i=1\}} \left\{ \ln \left[\phi \left(\frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma} \right) \right] - \ln \sigma + \ln \left[\Phi \left(\frac{\mathbf{w}'_i \boldsymbol{\gamma} + \rho \frac{y_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma}}{\sqrt{1 - \rho^2}} \right) \right] - \ln [\Phi(\mathbf{x}'_i \boldsymbol{\beta} / \sigma)] \right\} \end{aligned}$$

Multivariate Limited Dependent Models

The multivariate model is similar to bivariate models. The generic form of the multivariate limited dependent variable model is

$$\begin{aligned} y_{1i}^* &= \mathbf{x}'_{1i} \boldsymbol{\beta}_1 + \epsilon_{1i} \\ y_{2i}^* &= \mathbf{x}'_{2i} \boldsymbol{\beta}_2 + \epsilon_{2i} \\ &\dots \\ y_{mi}^* &= \mathbf{x}'_{mi} \boldsymbol{\beta}_m + \epsilon_{mi} \end{aligned}$$

where m is the number of models to be estimated. The vector ϵ has multivariate normal distribution with mean 0 and variance-covariance matrix Σ . Similar to bivariate models, the likelihood may involve computing multivariate normal integrations. This is done using Monte Carlo integration. (See Genz (1992) and Hajivassiliou and McFadden (1998).)

When the number of equations, N , increases in a system, the number of parameters increases at the rate of N^2 because of the correlation matrix. When the number of parameters is large, sometimes the optimization converges but some of the standard deviations are missing. This usually means that the model is over-parameterized. The default method for computing the covariance is to use the inverse Hessian matrix. The Hessian is computed by finite differences, and in over-parameterized cases, the inverse cannot be computed. It is recommended that you reduce the number of parameters in such cases. Sometimes using the outer product covariance matrix (COVEST=OP option) may also help.

Tests on Parameters

Tests on Parameters

In general, the hypothesis tested can be written as

$$H_0 : \mathbf{h}(\theta) = 0$$

where $\mathbf{h}(\theta)$ is an r by 1 vector valued function of the parameters θ given by the r expressions specified in the TEST statement.

Let \hat{V} be the estimate of the covariance matrix of $\hat{\theta}$. Let $\hat{\theta}$ be the unconstrained estimate of θ and $\tilde{\theta}$ be the constrained estimate of θ such that $h(\tilde{\theta}) = 0$. Let

$$A(\theta) = \partial h(\theta) / \partial \theta \big|_{\hat{\theta}}$$

Using this notation, the test statistics for the three kinds of tests are computed as follows.

The Wald test statistic is defined as

$$W = h'(\hat{\theta}) \left(A(\hat{\theta}) \hat{V} A'(\hat{\theta}) \right)^{-1} h(\hat{\theta})$$

The Wald test is not invariant to reparameterization of the model (Gregory 1985; Gallant 1987, p. 219). For more information about the theoretical properties of the Wald test, see Phillips and Park (1988).

The Lagrange multiplier test statistic is

$$LM = \lambda' A(\tilde{\theta}) \tilde{V} A'(\tilde{\theta}) \lambda$$

where λ is the vector of Lagrange multipliers from the computation of the restricted estimate $\tilde{\theta}$.

The likelihood ratio test statistic is

$$LR = 2 \left(L(\hat{\theta}) - L(\tilde{\theta}) \right)$$

where $\tilde{\theta}$ represents the constrained estimate of θ and L is the concentrated log-likelihood value.

For each kind of test, under the null hypothesis the test statistic is asymptotically distributed as a χ^2 random variable with r degrees of freedom, where r is the number of expressions in the TEST statement. The p -values reported for the tests are computed from the $\chi^2(r)$ distribution and are only asymptotically valid.

Monte Carlo simulations suggest that the asymptotic distribution of the Wald test is a poorer approximation to its small sample distribution than that of the other two tests. However, the Wald test has the lowest computational cost, since it does not require computation of the constrained estimate $\tilde{\theta}$.

The following is an example of using the TEST statement to perform a likelihood ratio test:

```
proc qlim;
  model y = x1 x2 x3;
  test x1 = 0, x2 * .5 + 2 * x3 = 0 /lr;
run;
```

Output to SAS Data Set

XBeta, Predicted, Residual

Xbeta is the structural part on the right-hand side of the model. Predicted value is the predicted dependent variable value. For censored variables, if the predicted value is outside the boundaries, it is reported as the closest boundary. For discrete variables, it is the level whose boundaries Xbeta falls between. Residual is defined only for continuous variables and is defined as

$$\text{Residual} = \text{Observed} - \text{Predicted}$$

Error Standard Deviation

Error standard deviation is σ_i in the model. It varies only when the HETERO statement is used.

Marginal Effects

Marginal effect is defined as a contribution of one control variable to the response variable. For the binary choice model with two response categories, $\mu_0 = -\infty$, $\mu_1 = 0$, $\mu_2 = \infty$; and ordinal response model with M response categories, μ_0, \dots, μ_M , define

$$R_{i,j} = \mu_j - \mathbf{x}'_i \boldsymbol{\beta}$$

The probability that the unobserved dependent variable is contained in the j th category can be written as

$$P[\mu_{j-1} < y_i^* \leq \mu_j] = F(R_{i,j}) - F(R_{i,j-1})$$

The marginal effect of changes in the regressors on the probability of $y_i = j$ is then

$$\frac{\partial \text{Prob}[y_i = j]}{\partial \mathbf{x}} = [f(\mu_{j-1} - \mathbf{x}'_i \boldsymbol{\beta}) - f(\mu_j - \mathbf{x}'_i \boldsymbol{\beta})] \boldsymbol{\beta}$$

where $f(x) = \frac{dF(x)}{dx}$. In particular,

$$f(x) = \frac{dF(x)}{dx} = \begin{cases} \frac{1}{\sqrt{2\pi}} e^{-x^2/2} & \text{(probit)} \\ \frac{e^{-x}}{[1+e^{(-x)}]^2} & \text{(logit)} \end{cases}$$

The marginal effects in the Box-Cox regression model are

$$\frac{\partial E[y_i]}{\partial \mathbf{x}} = \boldsymbol{\beta} \frac{x^{\lambda_k - 1}}{y^{\lambda_0 - 1}}$$

The marginal effects in the truncated regression model are

$$\frac{\partial E[y_i | L_i < y_i^* < R_i]}{\partial \mathbf{x}} = \boldsymbol{\beta} \left[1 - \frac{(\phi(a_i) - \phi(b_i))^2}{(\Phi(b_i) - \Phi(a_i))^2} + \frac{a_i \phi(a_i) - b_i \phi(b_i)}{\Phi(b_i) - \Phi(a_i)} \right]$$

where $a_i = \frac{L_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma_i}$ and $b_i = \frac{R_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma_i}$.

The marginal effects in the censored regression model are

$$\frac{\partial E[y | \mathbf{x}_i]}{\partial \mathbf{x}} = \boldsymbol{\beta} \times \text{Prob}[L_i < y_i^* < R_i]$$

Inverse Mills Ratio, Expected and Conditionally Expected Values

Expected and conditionally expected values are computed only for continuous variables. The inverse Mills ratio is computed for censored or truncated continuous, binary discrete, and selection endogenous variables.

Let L_i and R_i be the lower boundary and upper boundary, respectively, for the y_i . Define $a_i = \frac{L_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma_i}$ and $b_i = \frac{R_i - \mathbf{x}'_i \boldsymbol{\beta}}{\sigma_i}$. Then the inverse Mills ratio is defined as

$$\lambda = \frac{(\phi(a_i) - \phi(b_i))}{(\Phi(b_i) - \Phi(a_i))}$$

for a continuous variable and defined as

$$\lambda = \frac{\phi(\mathbf{x}'_i \boldsymbol{\beta})}{\Phi(\mathbf{x}'_i \boldsymbol{\beta})}$$

for a binary discrete variable.

The expected value is the unconditional expectation of the dependent variable. For a censored variable, it is

$$E[y_i] = \Phi(a_i)L_i + (\mathbf{x}'_i \boldsymbol{\beta} + \lambda \sigma_i)(\Phi(b_i) - \Phi(a_i)) + (1 - \Phi(b_i))R_i$$

For a left-censored variable ($R_i = \infty$), this formula is

$$E[y_i] = \Phi(a_i)L_i + (\mathbf{x}'_i \boldsymbol{\beta} + \lambda \sigma_i)(1 - \Phi(a_i))$$

where $\lambda = \frac{\phi(a_i)}{1 - \Phi(a_i)}$.

For a right-censored variable ($L_i = -\infty$), this formula is

$$E[y_i] = (\mathbf{x}'_i \boldsymbol{\beta} + \lambda \sigma_i)\Phi(b_i) + (1 - \Phi(b_i))R_i$$

where $\lambda = -\frac{\phi(b_i)}{\Phi(b_i)}$.

For a noncensored variable, this formula is

$$E[y_i] = \mathbf{x}'_i \boldsymbol{\beta}$$

The conditional expected value is the expectation given that the variable is inside the boundaries:

$$E[y_i | L_i < y_i < R_i] = \mathbf{x}'_i \boldsymbol{\beta} + \lambda \sigma_i$$

Probability

Probability applies only to discrete responses. It is the marginal probability that the discrete response is taking the value of the observation. If the **PROBALL** option is specified, then the probability for all of the possible responses of the discrete variables is computed.

Technical Efficiency

Technical efficiency for each producer is computed only for stochastic frontier models.

In general, the stochastic production frontier can be written as

$$y_i = f(x_i; \beta) \exp\{v_i\} TE_i$$

where y_i denotes producer i 's actual output, $f(\cdot)$ is the deterministic part of production frontier, $\exp\{v_i\}$ is a producer-specific error term, and TE_i is the technical efficiency coefficient, which can be written as

$$TE_i = \frac{y_i}{f(x_i; \beta) \exp\{v_i\}}.$$

In the case of a Cobb-Douglas production function, $TE_i = \exp\{-u_i\}$. See the section “[Stochastic Frontier Production and Cost Models](#)” on page 1450.

Cost frontier can be written in general as

$$E_i = c(y_i, w_i; \beta) \exp\{v_i\} / CE_i$$

where w_i denotes producer i 's input prices, $c(\cdot)$ is the deterministic part of cost frontier, $\exp\{v_i\}$ is a producer-specific error term, and CE_i is the cost efficiency coefficient, which can be written as

$$CE_i = \frac{c(x_i, w_i; \beta) \exp\{v_i\}}{E_i}$$

In the case of a Cobb-Douglas cost function, $CE_i = \exp\{-u_i\}$. See the section “[Stochastic Frontier Production and Cost Models](#)” on page 1450. Hence, both technical and cost efficiency coefficients are the same. The estimates of technical efficiency are provided in the following subsections.

Normal-Half Normal Model

Define $\mu_* = -\epsilon\sigma_u^2/\sigma^2$ and $\sigma_*^2 = \sigma_u^2\sigma_v^2/\sigma^2$. Then, as it is shown by Jondrow et al. (1982), conditional density is as follows:

$$f(u|\epsilon) = \frac{f(u, \epsilon)}{f(\epsilon)} = \frac{1}{\sqrt{2\pi}\sigma_*} \exp\left\{-\frac{(u - \mu_*)^2}{2\sigma_*^2}\right\} \Bigg/ \left[1 - \Phi\left(-\frac{\mu_*}{\sigma_*}\right)\right]$$

Hence, $f(u|\epsilon)$ is the density for $N^+(\mu_*, \sigma_*^2)$.

Using this result, it follows that the estimate of technical efficiency (Battese and Coelli, 1988) is

$$TE1_i = E(\exp\{-u_i\}|\epsilon_i) = \left[\frac{1 - \Phi(\sigma_* - \mu_{*i}/\sigma_*)}{1 - \Phi(-\mu_{*i}/\sigma_*)} \right] \exp\left\{-\mu_{*i} + \frac{1}{2}\sigma_*^2\right\}$$

The second version of the estimate (Jondrow et al., 1982) is

$$TE2_i = \exp\{-E(u_i|\epsilon_i)\}$$

where

$$E(u_i|\epsilon_i) = \mu_{*i} + \sigma_* \left[\frac{\phi(-\mu_{*i}/\sigma_*)}{1 - \Phi(-\mu_{*i}/\sigma_*)} \right] = \sigma_* \left[\frac{\phi(\epsilon_i \lambda/\sigma)}{1 - \Phi(\epsilon_i \lambda/\sigma)} - \left(\frac{\epsilon_i \lambda}{\sigma} \right) \right]$$

Normal-Exponential Model

Define $A = -\tilde{\mu}/\sigma_v$ and $\tilde{\mu} = -\epsilon - \sigma_v^2/\sigma_u$. Then, as it is shown by Kumbhakar and Lovell (2000), conditional density is as follows:

$$f(u|\epsilon) = \frac{1}{\sqrt{2\pi}\sigma_v\Phi(-\tilde{\mu}/\sigma_v)} \exp\left\{-\frac{(u - \tilde{\mu})^2}{2\sigma^2}\right\}$$

Hence, $f(u|\epsilon)$ is the density for $N^+(\tilde{\mu}, \sigma_v^2)$.

Using this result, it follows that the estimate of technical efficiency is

$$TE1_i = E(\exp\{-u_i\}|\epsilon_i) = \left[\frac{1 - \Phi(\sigma_v - \tilde{\mu}_i/\sigma_v)}{1 - \Phi(-\tilde{\mu}_i/\sigma_v)} \right] \exp\left\{-\tilde{\mu}_i + \frac{1}{2}\sigma_v^2\right\}$$

The second version of the estimate is

$$TE2_i = \exp\{-E(u_i|\epsilon_i)\}$$

where

$$E(u_i|\epsilon_i) = \tilde{\mu}_i + \sigma_v \left[\frac{\phi(-\tilde{\mu}_i/\sigma_v)}{1 - \Phi(-\tilde{\mu}_i/\sigma_v)} \right] = \sigma_v \left[\frac{\phi(A)}{\Phi(-A)} - A \right]$$

Normal-Truncated Normal Model

Define $\tilde{\mu} = (-\sigma_u^2\epsilon_i + \mu\sigma_v^2)/\sigma^2$ and $\sigma_*^2 = \sigma_u^2\sigma_v^2/\sigma^2$. Then, as it is shown by Kumbhakar and Lovell (2000), conditional density is as follows:

$$f(u|\epsilon) = \frac{1}{\sqrt{2\pi}\sigma_*[1 - \Phi(-\tilde{\mu}/\sigma_*)]} \exp\left\{-\frac{(u - \tilde{\mu})^2}{2\sigma_*^2}\right\}$$

Hence, $f(u|\epsilon)$ is the density for $N^+(\tilde{\mu}, \sigma_*^2)$.

Using this result, it follows that the estimate of technical efficiency is

$$TE1_i = E(\exp\{-u_i\}|\epsilon_i) = \frac{1 - \Phi(\sigma_* - \tilde{\mu}_i/\sigma_*)}{1 - \Phi(-\tilde{\mu}_i/\sigma_*)} \exp\left\{-\tilde{\mu}_i + \frac{1}{2}\sigma_*^2\right\}$$

The second version of the estimate is

$$TE2_i = \exp\{-E(u_i|\epsilon_i)\}$$

where

$$E(u_i|\epsilon_i) = \tilde{\mu}_i + \sigma_* \left[\frac{\phi(\tilde{\mu}_i/\sigma_*)}{1 - \Phi(-\tilde{\mu}_i/\sigma_*)} \right]$$

OUTEST= Data Set

The OUTEST= data set contains all the parameters estimated in a MODEL statement. The OUTEST= option can be used when the PROC QLIM call contains one MODEL statement:

```
proc qlim data=a outest=e;
  model y = x1 x2 x3;
  endogenous y ~ censored(lb=0);
run;
```

Each parameter contains the estimate for the corresponding parameter in the corresponding model. In addition, the OUTEST= data set contains the following variables:

<code>_NAME_</code>	the name of the independent variable
<code>_TYPE_</code>	type of observation. PARM indicates the row of coefficients; STD indicates the row of standard deviations of the corresponding coefficients.
<code>_STATUS_</code>	convergence status for optimization

The rest of the columns correspond to the explanatory variables.

The OUTEST= data set contains one observation for the MODEL statement, giving the parameter estimates for that model. If the COVOUT option is specified, the OUTEST= data set includes additional observations for the MODEL statement, giving the rows of the covariance matrix of parameter estimates. For covariance observations, the value of the `_TYPE_` variable is COV, and the `_NAME_` variable identifies the parameter associated with that row of the covariance matrix. If the CORROUT option is specified, the OUTEST= data set includes additional observations for the MODEL statement, giving the rows of the correlation matrix of parameter estimates. For correlation observations, the value of the `_TYPE_` variable is CORR, and the `_NAME_` variable identifies the parameter associated with that row of the correlation matrix.

Naming

Naming of Parameters

When there is only one equation in the estimation, parameters are named in the same way as in other SAS procedures such as REG, PROBIT, and so on. The constant in the regression equation is called Intercept. The coefficients on independent variables are named by the independent variables. The standard deviation of the errors is called `_Sigma`. If there are Box-Cox transformations, the coefficients are named `_Lambdai`, where i increments from 1, or as specified by the user. The limits for the discrete dependent variable are named `_Limiti`. If the LIMIT=varying option is specified, then `_Limiti` starts from 1. If the LIMIT=varying option is not specified, then `_Limit1` is set to 0 and the limit parameters start from $i = 2$. If the HETERO statement is included, the coefficients of the independent variables in the hetero equation are called `_H.x`, where x is the name of the independent

variable. If the parameter name includes interaction terms, it needs to be enclosed in quotation marks followed by N . The following example restricts the parameter that includes the interaction term to be greater than zero:

```
proc qlim data=a;
  model y = x1|x2;
  endogenous y ~ discrete;
  restrict "x1*x2" > 0;
run;
```

When there are multiple equations in the estimation, the parameters in the main equation are named in the format of $y.x$, where y is the name of the dependent variable and x is the name of the independent variable. The standard deviation of the errors is called $_Sigma.y$. The correlation of the errors is called $_Rho$ for bivariate model. For the model with three variables it is $_Rho.y1.y2$, $_Rho.y1.y3$, $_Rho.y2.y3$. The construction of correlation names for multivariate models is analogous. Box-Cox parameters are called $_Lambdai.y$ and limit variables are called $_Limiti.y$. Parameters in the HETERO statement are named as $_H.y.x$. In the OUTEST= data set, all variables are changed from $_'$ to $_'$.

Naming of Output Variables

The following table shows the option in the OUTPUT statement, with the corresponding variable names and their explanation.

Option	Name	Explanation
PREDICTED	P_y	Predicted value of y
RESIDUAL	RESID_y	Residual of y , (y -Predicted Y)
XBETA	XBETA_y	Structure part ($\mathbf{x}'\boldsymbol{\beta}$) of y equation
ERRSTD	ERRSTD_y	Standard deviation of error term
PROB	PROB_y	Probability that y is taking the observed value in this observation (discrete y only)
PROBALL	PROB i _y	Probability that y is taking the i th value (discrete y only)
MILLS	MILLS_y	Inverse Mills ratio for y
EXPECTED	EXPCT_y	Unconditional expected value of y
CONDITIONAL	CEXPCT_y	Conditional expected value of y , condition on the truncation.
MARGINAL	MEFF_x	Marginal effect of x on y ($\frac{\partial y}{\partial x}$) with single equation
	MEFF_y_x	Marginal effect of x on y ($\frac{\partial y}{\partial x}$) with multiple equations
	MEFF_Pi_x	Marginal effect of x on y ($\frac{\partial Prob(y=i)}{\partial x}$) with single equation and discrete y
	MEFF_Pi_y_x	Marginal effect of x on y ($\frac{\partial Prob(y=i)}{\partial x}$) with multiple equations and discrete y
TE1	TE1	Technical efficiency estimate for each producer proposed by Battese and Coelli (1988)
TE2	TE2	Technical efficiency estimate for each producer proposed by Jondrow et al. (1982)

If you prefer to name the output variables differently, you can use the RENAME option in the data set. For example, the following statements rename the residual of y as *Resid*:

```
proc qlim data=one;
  model y = x1-x10 / censored;
  output out=outds(rename=(resid_y=resid)) residual;
run;
```

ODS Table Names

PROC QLIM assigns a name to each table it creates. You can use these names to denote the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the [Table 21.2](#).

Examples: QLIM Procedure

Example 21.1: Ordered Data Modeling

Cameron and Trivedi (1986) studied Australian Health Survey data. Variable definitions are given in Cameron and Trivedi (1998, p. 68).

The dependent variable, `dvisits`, has nine ordered values. The following SAS statements estimate the ordinal probit model:

```

/*-- Ordered Discrete Responses --*/
proc qlim data=docvisit;
  model dvisits = sex age agesq income levyplus
              freepoor freerepa illness actdays hscore
              chcond1 chcond2 / discrete;
run;

```

The output of the QLIM procedure for ordered data modeling is shown in [Output 21.1.1](#).

_Limit8	1	2.789796	0.156189	17.86	<.0001

By default, ordinal probit/logit models are estimated assuming that the first threshold or limit parameter (μ_1) is 0. However, this parameter can also be estimated when the LIMIT1=VARYING option is specified. The probability that y_i^* belongs to the j th category is defined as

$$P[\mu_{j-1} < y_i^* < \mu_j] = F(\mu_j - \mathbf{x}'_i \boldsymbol{\beta}) - F(\mu_{j-1} - \mathbf{x}'_i \boldsymbol{\beta})$$

where $F(\cdot)$ is the logistic or standard normal CDF, $\mu_0 = -\infty$ and $\mu_9 = \infty$. Output 21.1.2 lists ordinal probit estimates computed in the following program. Note that the intercept term is suppressed for model identification when μ_1 is estimated.

```

/*-- Ordered Probit --*/
proc qlim data=docvisit;
  model dvisits = sex age agesq income levyplus
             freepoor freerepa illness actdays hscore
             chcond1 chcond2 / discrete(d=normal) limit1=varying;
run;

```

Example 21.2: Tobit Analysis

The following statements show a subset of the Mroz (1987) data set. In these data, Hours is the number of hours the wife worked outside the household in a given year, Yrs_Ed is the years of education, and Yrs_Exp is the years of work experience. A Tobit model will be fit to the hours worked with years of education and experience as covariates.

By the nature of the data it is clear that there are a number of women who committed some positive number of hours to outside work ($y_i > 0$ is observed). There are also a number of women who did not work at all ($y_i = 0$ is observed). This gives us the following model:

$$y_i^* = \mathbf{x}_i' \boldsymbol{\beta} + \epsilon_i$$

$$y_i = \begin{cases} y_i^* & \text{if } y_i^* > 0 \\ 0 & \text{if } y_i^* \leq 0 \end{cases}$$

where $\epsilon_i \sim iidN(0, \sigma^2)$. The set of explanatory variables is denoted by \mathbf{x}_i .

```

_Sigma	1	1582.859635	390.076480	4.06	<.0001

In the “Parameter Estimates” table there are four rows. The first three of these rows correspond to the vector estimate of the regression coefficients β . The last one is called `_Sigma`, which corresponds to the estimate of the error variance σ .

Example 21.3: Bivariate Probit Analysis

This example shows how to estimate a bivariate probit model. Note the `INIT` statement in the following program, which sets the initial values for some parameters in the optimization:

```

data a;
  keep y1 y2 x1 x2;
  do i = 1 to 500;
    x1 = rannor( 19283 );
    x2 = rannor( 19283 );
    u1 = rannor( 19283 );
    u2 = rannor( 19283 );
    y11 = 1 + 2 * x1 + 3 * x2 + u1;
    y21 = 3 + 4 * x1 - 2 * x2 + u1*.2 + u2;
    if ( y11 > 0 ) then y1 = 1;
    else y1 = 0;
    if ( y21 > 0 ) then y2 = 1;
    else y2 = 0;
    output;
  end;
run;

/*-- Bivariate Probit --*/
proc qlim data=a method=qn;
  init y1.x1 2.8, y1.x2 2.1, _rho .1;
  model y1 = x1 x2;
  model y2 = x1 x2;
  endogenous y1 y2 ~ discrete;
run;

```

The output of the QLIM procedure is shown in [Output 21.3.1](#).

Output 21.3.1 Bivariate Probit Analysis Results

Example 21.4: Sample Selection Model

This example illustrates the use of PROC QLIM for sample selection models. The data set is the same one from Mroz (1987). The goal is to estimate a wage offer function for married women, accounting for potential selection bias. Of the 753 women, the wage is observed for 428 working women. The labor force participation equation estimated in the introductory example is used for selection. The wage equation uses log wage (`lwage`) as the dependent variable. The explanatory variables in the wage equation are the woman's years of schooling (`educ`), wife's labor experience (`exper`), and square of experience (`expersq`). The program is as follows:

```

/*-- Sample Selection --*/
proc qlim data=mroz;
  model inlf = nwifeinc educ exper expersq
             age kidslt6 kidsge6 /discrete;
  model lwage = educ exper expersq / select(inlf=1);
run;

```

The output of the QLIM procedure is shown in [Output 21.4.1](#).

Output 21.4.1 Sample Selection

Binary Data					
The QLIM Procedure					
Model Fit Summary					
Number of Endogenous Variables					2
Endogenous Variable				inlf	lwage
Number of Observations					753
Log Likelihood					-832.88509
Maximum Absolute Gradient					0.00502
Number of Iterations					78
Optimization Method					Quasi-Newton
AIC					1694
Schwarz Criterion					1759
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
lwage.Intercept	1	-0.552716	0.260371	-2.12	0.0338
lwage.educ	1	0.108351	0.014861	7.29	<.0001
lwage.exper	1	0.042837	0.014878	2.88	0.0040
lwage.expersq	1	-0.000837	0.000417	-2.01	0.0449
_Sigma.lwage	1	0.663397	0.022706	29.22	<.0001
inlf.Intercept	1	0.266459	0.508954	0.52	0.6006
inlf.nwifeinc	1	-0.012132	0.004877	-2.49	0.0129
inlf.educ	1	0.131341	0.025383	5.17	<.0001
inlf.exper	1	0.123282	0.018728	6.58	<.0001
inlf.expersq	1	-0.001886	0.000601	-3.14	0.0017
inlf.age	1	-0.052829	0.008479	-6.23	<.0001
inlf.kidslt6	1	-0.867398	0.118647	-7.31	<.0001
inlf.kidsge6	1	0.035872	0.043476	0.83	0.4093
_Rho	1	0.026617	0.147073	0.18	0.8564

Note the correlation estimate is insignificant. This indicates that selection bias is not a big problem in the estimation of wage equation.

Example 21.5: Sample Selection Model with Truncation and Censoring

In this example the data are generated such that the selection variable is discrete and the variable Y is truncated from below by zero. The program follows, with the results shown in Output 21.5.1:

```
data trunc;
  keep z y x1 x2;
  do i = 1 to 500;
    x1 = rannor( 19283 );
    x2 = rannor( 19283 );
```

```

u1 = rannor( 19283 );
u2 = rannor( 19283 );
z1 = 1 + 2 * x1 + 3 * x2 + u1;
y = 3 + 4 * x1 - 2 * x2 + u1*.2 + u2;
if ( z1 > 0 ) then z = 1;
else z = 0;
if y>=0 then output;
end;
run;

/*-- Sample Selection with Truncation --*/
proc qlim data=trunc method=qn;
  model z = x1 x2 / discrete;
  model y = x1 x2 / select(z=1) truncated(lb=0);
run;

```

Output 21.5.1 Sample Selection with Truncation

Example 21.6: Types of Tobit Models

The following five examples show how to estimate different types of Tobit models (see “Types of Tobit Models” on page 1447). Output 21.6.1 through Output 21.6.5 show the results of the corresponding programs.

Type 1 Tobit

```

data a1;
  keep y x;
  do i = 1 to 500;
    x = rannor( 19283 );
    u = rannor( 19283 );
    y1 = 1 + 2 * x + u;
    if ( y1 > 0 ) then y = y1;
    else          y = 0;
    output;
  end;
run;

/*-- Type 1 Tobit --*/
proc qlim data=a1 method=qn;
  model y = x;
  endogenous y ~ censored(lb=0);
run;

```

Example 21.7: Stochastic Frontier Models

This example illustrates the estimation of stochastic frontier production and cost models.

First, a production function model is estimated. The data for this example were collected by Christensen Associates; they represent a sample of 125 observations on inputs and output for 10 airlines between 1970 and 1984. The explanatory variables (inputs) are fuel (LF), materials (LM), equipment (LE), labor (LL), and property (LP), and (LQ) is an index that represents passengers, charter, mail, and freight transported.

The following statements create the dataset:

```

title1 'Stochastic Frontier Production Model';
data airlines;
  input TS FIRM NI LQ LF LM LE LL LP;
datalines;
1 1 15 -0.0484 0.2473 0.2335 0.2294 0.2246 0.2124
1 1 15 -0.0133 0.2603 0.2492 0.241 0.2216 0.1069
2 1 15 0.088 0.2666 0.3273 0.3365 0.2039 0.0865

... more lines ...

```

The following statements estimate a stochastic frontier exponential production model that uses Christensen Associates data:

```

/*-- Stochastic Frontier Production Model --*/
proc qlim data=airlines;
  model LQ=LF LM LE LL LP;
  endogenous LQ ~ frontier (type=exponential production);
run;

```

Figure 21.7.1 shows the results from this production model.

Output 21.7.1 Stochastic Frontier Production Model

_Sigma_u	1	0.060611	0.017603	3.44	0.0006

Similarly, the stochastic frontier production function can be estimated with (type=half) or (type=truncated) options that represent half-normal and truncated normal production models.

In the next step, stochastic frontier cost function is estimated. The data for the cost model are provided by Christensen and Greene (1976). The data describe costs and production inputs of 145 U.S. electricity producers in 1955. The model being estimated follows the nonhomogenous version of the Cobb-Douglas cost function:

$$\log\left(\frac{\text{Cost}}{\text{FPrice}}\right) = \beta_0 + \beta_1 \log\left(\frac{\text{KPrice}}{\text{FPrice}}\right) + \beta_2 \log\left(\frac{\text{LPrice}}{\text{FPrice}}\right) + \beta_3 \log(\text{Output}) + \beta_4 \frac{1}{2} \log(\text{Output})^2 + \epsilon$$

All dollar values are normalized by fuel price. The quadratic log of the output is added to capture nonlinearities due to scale effects in cost functions. New variables, log_C_PF, log_PK_PF, log_PL_PF, log_y, and log_y_sq, are created to reflect transformations. The following statements create the data set and transformed variables:

```
data electricity;
    input Firm Year Cost Output LPrice LShare KPrice KShare FPrice FShare;

Overview: SEVERITY Procedure

The SEVERITY procedure estimates parameters of any arbitrary continuous probability distribution that is used to model magnitude (severity) of a continuous-valued event of interest. Some examples of such events are loss amounts paid by an insurance company and demand of a product as depicted by its sales. PROC SEVERITY is especially useful when the severity of an event does not follow typical distributions, such as the normal distribution, that are often assumed by standard statistical methods.

PROC SEVERITY provides a default set of probability distribution models that includes the Burr, exponential, gamma, generalized Pareto, inverse Gaussian (Wald), lognormal, Pareto, and Weibull distributions. In the simplest form, you can estimate the parameters of any of these distributions by using a list of severity values that are recorded in a SAS data set. The values can optionally be grouped by a set of BY variables. PROC SEVERITY computes the estimates of the model parameters, their standard errors, and their covariance structure by using the maximum likelihood method for each of the BY groups.

PROC SEVERITY can fit multiple distributions at the same time and choose the best distribution according to a specified selection criterion. Seven different statistics of fit can be used as selection criteria. They are log likelihood, Akaike's information criterion (AIC), corrected Akaike's information criterion (AICC), Schwarz Bayesian information criterion (BIC), Kolmogorov-Smirnov statistic (KS), Anderson-Darling statistic (AD), and Cramér-von-Mises statistic (CvM).

You can request the procedure to output the status of the estimation process, the parameter estimates and their standard errors, the estimated covariance structure of the parameters, the statistics of fit, estimated cumulative distribution function (CDF) for each of the specified distributions, and the empirical distribution function (EDF) estimate (which is used to compute the KS, AD, and CvM statistics of fit).

The following key features of PROC SEVERITY make it different and unique from other SAS procedures that can estimate continuous probability distributions:

- PROC SEVERITY enables you to fit a distribution model when the severity values are left-truncated or right-censored or both. This is especially useful in applications with an insurance-type model where a severity (loss) gets reported and recorded only if it is greater than the deductible amount (left-truncation) and a severity value greater than or equal to the policy limit gets recorded at the limit (right-censoring). The procedure also enables you to specify a *probability of observability* for the left-truncated data, which is a probability of observing values greater than the left-truncation threshold. This additional information can be useful in certain applications to more correctly model the distribution of the severity of events.

When left-truncation or right-censoring is specified, PROC SEVERITY can compute the empirical distribution function (EDF) estimate by using Kaplan-Meier's product-limit estimator or one of its robust variants.

- PROC SEVERITY enables you to define any arbitrary continuous parametric distribution model and to estimate its parameters. You just need to define the key components of the distribution, such as its probability density function (PDF) and cumulative distribution function

(CDF), as a set of functions and subroutines written with the FCMP procedure, which is part of Base SAS software. As long as the functions and subroutines follow certain rules, PROC SEVERITY can fit the distribution model defined by them.

- PROC SEVERITY can model the effect of exogenous or regressor variables on a probability distribution, as long as it has a scale parameter. A linear combination of the regressor variables is assumed to affect the scale parameter via an exponential link function.

If a distribution does not have a scale parameter, then either it needs to have another parameter that can be derived from a scale parameter by using a supported transformation or it needs to be reparameterized to have a scale parameter. If neither of these is possible, then regression effects cannot be modeled.

These features and the core functionality are described in detail in the following sections.

Getting Started: SEVERITY Procedure

This section outlines the use of the SEVERITY procedure to fit continuous probability distribution models. It illustrates three different examples of different features of the procedure.

A Simple Example of Fitting Predefined Distributions

The simplest way to use PROC SEVERITY is to fit all the predefined distributions to a set of values and let the procedure identify the best fitting distribution.

Consider a lognormal distribution, whose probability density function (PDF) f and cumulative distribution function (CDF) F are as follows, respectively, where Φ denotes the CDF of the standard normal distribution:

$$f(x; \mu, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{\log(x)-\mu}{\sigma}\right)^2} \quad \text{and} \quad F(x; \mu, \sigma) = \Phi\left(\frac{\log(x)-\mu}{\sigma}\right)$$

The following DATA step statements simulate a sample from a lognormal distribution with population parameters $\mu = 1.5$ and $\sigma = 0.25$, and store the sample in the variable Y of a data set WORK.TEST_SEV1:

```
/*----- Simple Lognormal Example -----*/
data test_sev1(keep=y label='Simple Lognormal Sample');
  call streaminit(45678);
  label y='Response Variable';
  Mu = 1.5;
  Sigma = 0.25;
  do n = 1 to 100;
    y = exp(Mu) * rand('LOGNORMAL')**Sigma;
    output;
  end;
run;
```

The following statements enable ODS Graphics, fit all the predefined distribution models to the values of Y, and identify the best distribution according to the corrected Akaike's information criterion (AICC):

```
ods graphics on;

proc severity data=test_sev1;
  model y / crit=aicc;
run;
```

The ODS GRAPHICS ON statement enables PROC SEVERITY to generate the default graphics, the PROC SEVERITY statement specifies the input data set, and the MODEL statement specifies the variable to be modeled along with the model selection criterion.

Some of the default output displayed by this step is shown in Figure 22.1 through Figure 22.5. First, information about the input data set is displayed followed by the model selection table, as shown in Figure 22.1. The model selection table displays the convergence status, the value of the selection criterion, and the selection status for each of the candidate models. The Converged column indicates whether the estimation process for a given distribution model has converged, might have converged, or failed. The Selected column indicates whether a given distribution has the best fit for the data according to the selection criterion. For this example, the lognormal distribution model is selected, because it has the lowest value for the selection criterion.

Figure 22.1 Data Set Information and Model Selection Table

The SEVERITY Procedure			
Input Data Set			
Name		WORK.TEST_SEV1	
Label	Simple Lognormal	Sample	
Model Selection Table			
Distribution	Converged	Corrected Akaike's Information Criterion	Selected
Burr	Yes	322.50845	No
Exp	Yes	508.12287	No
Gamma	Yes	320.50264	No
Igauss	Yes	319.61652	No
Logn	Yes	319.56579	Yes
Pareto	Yes	510.28172	No
Gpd	Yes	510.20576	No
Weibull	Yes	334.82373	No

Next, two comparative plots are prepared. These plots enable you to visually verify how the models differ from each other and from the nonparametric estimates. The plot in Figure 22.2 displays the cumulative distribution function (CDF) estimates of all the models and the estimates of the empirical distribution function (EDF). The CDF plot indicates that the Exp (exponential), Pareto, and Gpd

(generalized Pareto) distributions are a poor fit as compared to the EDF estimate. The Weibull distribution is also a poor fit, although not as poor as exponential, Pareto, and Gpd. The other four distributions seem to be quite close to each other and to the EDF estimate.

Figure 22.2 Comparison of EDF and CDF Estimates of the Fitted Models

The plot in [Figure 22.3](#) displays the probability density function (PDF) estimates of all the models and the nonparametric kernel and histogram estimates. The PDF plot enables better visual comparison between the Burr, Gamma, Igauss (inverse Gaussian), and Logn (lognormal) models. The Burr and Gamma differ significantly from the Igauss and Logn distributions in the central portion of the range of Y values, while the latter two fit the data almost identically. This provides a visual confirmation of the information in the model selection table of [Figure 22.1](#), which indicates that the AICC values of Igauss and Logn distributions are very close.

Figure 22.3 Comparison of PDF Estimates of the Fitted Models

The comparative plots are followed by the estimation information for each of the candidate models. The information for the lognormal model, which is the best fitting model, is shown in Figure 22.4. The first table displays a summary of the distribution. The second table displays the convergence status. This is followed by a summary of the optimization process which indicates the technique used, the number of iterations, the number of times the objective function was evaluated, and the log likelihood attained at the end of the optimization. Since the model with lognormal distribution has converged, PROC SEVERITY displays its statistics of fit and parameter estimates. The estimates of $\mu=1.49605$ and $\sigma=0.26243$ are quite close to the population parameters of $\mu=1.5$ and $\sigma=0.25$ from which the sample was generated. The p -value for each estimate indicates the rejection of the null hypothesis that the estimate is 0, implying that both the estimates are significantly different from 0.

An Example with Left-Truncation and Right-Censoring

PROC SEVERITY enables you to specify that the response variable values are left-truncated or right-censored. The following DATA step expands the data set of the previous example to simulate a scenario that is typically encountered by an automobile insurance company. The values of the variable Y represent the loss values on claims that are reported to an auto insurance company. The variable THRESHOLD records the deductible on the insurance policy. If the actual value of Y is less than or equal to the deductible, then it is unobservable and does not get recorded. In other words, THRESHOLD specifies the left-truncation of Y. The ISCENS variable indicates whether the loss exceeds the policy limit. ISCENS=1 means that the actual value of Y is greater than the recorded value; that is, Y is right-censored. If ISCENS has any other value, then the recorded value of Y is the actual value of the loss.

```

/*----- Lognormal Model with left-truncation and censoring -----*/
data test_sev2(keep=y iscens threshold
    label='A Lognormal Sample With Censoring and Truncation');
set test_sev1;
label y='Censored & Truncated Response';
if _n_ = 1 then call streaminit(45679);

/* make about 20% of the observations left-truncated */
if (rand('UNIFORM') < 0.2) then
    threshold = y * (1 - rand('UNIFORM'));
else
    threshold = .;
/* make about 15% of the observations right-censored */
iscens = (rand('UNIFORM') < 0.15);
run;

```

The following statements use the AICC criterion to analyze which of the four predefined distributions (lognormal, Burr, gamma, and Weibull) has the best fit for the data:

```

proc severity data=test_sev2
    print=all plots(markcensored marktruncated)=pp;
model y(lt=threshold rc=iscens(1)) / crit=aicc;

dist logn;
dist burr;
dist gamma;
dist weibull;
run;

```

The MODEL statement specifies the left-truncation and right-censoring indicator variables. You need to specify that the value of 1 for the ISCENS variable indicates right-censoring, because the default indicator value is 0. Each candidate distribution needs to be specified by using a separate DIST statement. The PRINT= option in the PROC SEVERITY statement requests that all the displayed output be prepared. The PLOTS= option in the PROC SEVERITY statement requests that the P-P plots for each candidate distribution be prepared in addition to the default plots. It also instructs the procedure to mark the left-truncated and right-censored observations in the CDF plot.

Some of the key results prepared by PROC SEVERITY are shown in Figure 22.6 through Figure 22.11. The descriptive statistics of Y are shown in the second table of Figure 22.6. In addition to the estimates of the range, mean, and standard deviation of Y , the table also indicates the number of observations that are right-censored, left-truncated, and both right-censored and left-truncated. The “Model Selection Table” in Figure 22.6 shows that models with all the candidate distributions have converged and that the Logn (lognormal) model has the best fit for the data according to the AICC criterion.

Burr	Yes	302.66229	No
Gamma	Yes	299.45293	No
Weibull	Yes	309.26779	No

PROC SEVERITY also prepares a table that shows all the fit statistics for all the candidate models. It is useful to see which model would be the best fit according to each of the criteria. The table prepared for this example is shown in Figure 22.7. It indicates that the lognormal model is chosen by all the criteria.

Figure 22.7 Comparing All Statistics of Fit for the Truncated and Censored Data

All Fit Statistics Table					
Distribution	-2 Log Likelihood	AIC	AICC	BIC	KS
Logn	294.80301*	298.80301*	298.92672*	304.01335*	0.51824*
Burr	296.41229	302.41229	302.66229	310.22780	0.66984

Weibull	305.14408	309.14408	309.26779	314.35442	0.93307

All Fit Statistics Table		
Distribution	AD	CvM
Logn	0.34736*	0.05159*
Burr	0.36712	0.05726
Gamma	0.42921	0.05526
Weibull	1.40698	0.17465

The plot that compares EDF and CDF estimates is shown in [Figure 22.8](#). When left-truncation is specified, both the EDF and CDF estimates are conditional on the response variable being greater than the smallest left-truncation threshold in the sample. Notice the markers close to the X-axis of the plot. These indicate the values of Y that are left-truncated or right-censored.

Figure 22.8 EDF and CDF Estimates for the Truncated and Censored Data

In addition to the comparative plot, PROC SEVERITY produces a P-P plot for each of the models that has not failed to converge. It is a scatter plot of the EDF and the CDF estimates. The model for which the points are scattered closer to the unit-slope reference line is a better fit. The P-P plot for the lognormal distribution is shown in Figure 22.9. It indicates that the EDF and the CDF match very closely. In contrast, the P-P plot for the Weibull distribution, also shown in Figure 22.9, indicates a poor fit.

Figure 22.9 P-P Plots for the Lognormal and Weibull Models Fitted to Truncated and Censored Data

Figure 22.9 continued

Specifying Initial Values for Parameters

All the predefined distributions have parameter initialization functions built into them. For the current example, Figure 22.10 shows the initial values that are obtained by the predefined method for the Burr distribution. It also shows the summary of the optimization process and the final parameter estimates.

Figure 22.10 Burr Model Summary for the Truncated and Censored Data

Initial Parameter Values and Bounds for Burr Distribution			
Parameter	Initial Value	Lower Bound	Upper Bound
Theta	4.78102	1.05367E-8	Infty
Alpha	2.00000	1.05367E-8	Infty
Gamma	2.00000	1.05367E-8	Infty

Figure 22.10 continued

Optimization Summary for Burr Distribution				
Optimization Technique		Trust Region		
Number of Iterations				8
Number of Function Evaluations				21
Log Likelihood				-148.20614
Parameter Estimates for Burr Distribution				
Parameter	Estimate	Standard Error	t Value	Approx Pr > t
Theta	4.76980	0.62492	7.63	<.0001
Alpha	1.16363	0.58859	1.98	0.0509
Gamma	5.94081	1.05004	5.66	<.0001

You can specify a different set of initial values if estimates are available from fitting the distribution to similar data. For this example, the parameters of the Burr distribution can be initialized with the final parameter estimates of the Burr distribution that were obtained in the first example (shown in Figure 22.5). One of the ways in which you can specify the initial values is as follows:

```

/*----- Specifying initial values using INIT= option -----*/
proc severity data=test_sev2 print=(all) plots=none;
  model y(lt=threshold rc=iscens(1)) / crit=aicc;

  dist burr init=(theta=4.62348 alpha=1.15706 gamma=6.41227);
run;

```

The names of the parameters specified in the INIT option must match the names used in the definition of the distribution. The results obtained with these initial values are shown in Figure 22.11. These indicate that new set of initial values causes the optimizer to reach the same solution with fewer iterations and function evaluations as compared to the default initialization.

An Example of Modeling Regression Effects

Consider a scenario in which the magnitude of the response variable might be affected by some regressor (exogenous or independent) variables. The SEVERITY procedure enables you to model the effect of such variables on the distribution of the response variable via an exponential link function. In particular, if you have k random regressor variables denoted by x_j ($j = 1, \dots, k$), then the distribution of the response variable Y is assumed to have the form

$$Y \sim \exp\left(\sum_{j=1}^k \beta_j x_j\right) \cdot \mathcal{F}(\Theta)$$

where \mathcal{F} denotes the distribution of Y with parameters Θ and β_j ($j = 1, \dots, k$) denote the regression parameters (coefficients). For the effective distribution of Y to be a valid distribution from the same parametric family as \mathcal{F} , it is necessary for \mathcal{F} to have a scale parameter. The effective distribution of Y can be written as

$$Y \sim \mathcal{F}(\theta, \Omega)$$

where θ denotes the scale parameter and Ω denotes the set of nonscale parameters. The scale θ is affected by the regressors as

$$\theta = \theta_0 \cdot \exp\left(\sum_{j=1}^k \beta_j x_j\right)$$

where θ_0 denotes a *base* value of the scale parameter.

Given this form of the model, PROC SEVERITY allows a distribution to be a candidate for modeling regression effects only if it has an untransformed or a log-transformed scale parameter.

All the predefined distributions, except the lognormal distribution, have a direct scale parameter (that is, a parameter that is a scale parameter without any transformation). For the lognormal distribution, the parameter μ is a log-transformed scale parameter. This can be verified by replacing μ with a parameter $\theta = e^\mu$, which results in the following expressions for the PDF f and the CDF F in terms of θ and σ , respectively, where Φ denotes the CDF of the standard normal distribution:

$$f(x; \theta, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{\log(x) - \log(\theta)}{\sigma}\right)^2} \quad \text{and} \quad F(x; \theta, \sigma) = \Phi\left(\frac{\log(x) - \log(\theta)}{\sigma}\right)$$

With this parameterization, the PDF satisfies the $f(x; \theta, \sigma) = \frac{1}{\theta} f\left(\frac{x}{\theta}; 1, \sigma\right)$ condition and the CDF satisfies the $F(x; \theta, \sigma) = F\left(\frac{x}{\theta}; 1, \sigma\right)$ condition. This makes θ a scale parameter. Hence, $\mu = \log(\theta)$ is a log-transformed scale parameter and the lognormal distribution is eligible for modeling regression effects.

The following DATA step simulates a lognormal sample whose scale is decided by the values of the three regressors X1, X2, and X3 as follows:

$$\mu = \log(\theta) = 1 + 0.75 X1 - X2 + 0.25 X3$$

```

/*----- Lognormal Model with Regressors -----*/
data test_sev3(keep=y x1-x3
                label='A Lognormal Sample Affected by Regressors');
array x{*} x1-x3;
array b{4} _TEMPORARY_ (1 0.75 -1 0.25);
call streaminit(45678);
label y='Response Influenced by Regressors';
Sigma = 0.25;
do n = 1 to 100;
    Mu = b(1); /* log of base value of scale */
    do i = 1 to dim(x);
        x(i) = rand('UNIFORM');
        Mu = Mu + b(i+1) * x(i);
    end;
    y = exp(Mu) * rand('LOGNORMAL')**Sigma;
    output;
end;
run;

```

The following PROC SEVERITY step fits the lognormal, Burr, and gamma distribution models to this data. The regressors are specified in the MODEL statement.

```

proc severity data=test_sev3 print=all;
    model y = x1-x3 / crit=aicc;

    dist logn;
    dist burr;
    dist gamma;
run;

```

Some of the key results prepared by PROC SEVERITY are shown in Figure 22.12 through Figure 22.16. The descriptive statistics of all the variables are shown in Figure 22.12.

Figure 22.12 Summary Results for the Regression Example

The distribution information and the convergence results of the lognormal model are shown in Figure 22.14. The iteration history gives you a summary of how the optimizer is traversing the surface of the log-likelihood function in its attempt to reach the optimum. Both the change in the log likelihood and the maximum gradient of the objective function with respect to any of the parameters typically approach 0 if the optimizer converges.

The final parameter estimates of the lognormal model are shown in Figure 22.15. All the estimates are significantly different from zero. The estimate that is reported for the parameter Mu is the base value for the log-transformed scale parameter μ . Let x_i ($1 \leq i \leq 3$) denote the observed value for regressor X_i . If the lognormal distribution is chosen to model Y , then the effective value of the parameter μ varies with the observed values of regressors as

$$\mu = 1.04047 + 0.65221 x_1 - 0.91116 x_2 + 0.16243 x_3$$

These estimated coefficients are reasonably close to the population parameters (that is, within one or two standard errors).

Figure 22.15 Parameter Estimates for the Lognormal Model with Regressors

Parameter Estimates for Logn Distribution				
Parameter	Estimate	Standard Error	t Value	Approx Pr > t

x3	0.16243	0.07782	2.09	0.0395

The estimates of the gamma distribution model, which is the best model according to a majority of the EDF-based statistics, are shown in Figure 22.16. The estimate that is reported for the parameter $Theta$ is the base value for the scale parameter θ . If the gamma distribution is chosen to model Y , then the effective value of the scale parameter is $\theta = 0.14293 \exp(0.64562 x_1 - 0.89831 x_2 + 0.14901 x_3)$.

PROC SEVERITY Statement

PROC SEVERITY *options* ;

The following options can be used in the PROC SEVERITY statement:

DATA=SAS-data-set

names the input data set. If the DATA= option is not specified, then the most recently created SAS data set is used.

OUTEST=SAS-data-set

names the output data set to contain estimates of the parameter values and their standard errors for each model whose parameter estimation process converges. Details of the variables in this data set are provided in the section “[OUTEST= Data Set](#)” on page 1553.

COVOUT

specifies that the OUTEST= data set contain the estimate of the covariance structure of the parameters. This option has no effect if the OUTEST= option is not specified. Details of how the covariance is reported in OUTEST= data set are provided in the section “[OUTEST= Data Set](#)” on page 1553.

VARDEF=option

specifies the denominator to use for computing the covariance estimates. The following options are available:

DF specifies that the number of nonmissing observations minus the model degrees of freedom (number of parameters) be used.

N specifies that the number of nonmissing observations be used.

The details of the covariance estimation are provided in the section “[Estimating Covariance and Standard Errors](#)” on page 1542.

OUTSTAT=SAS-data-set

names the output data set to contain the values of statistics of fit for each model whose parameter estimation process converges. Details of the variables in this data set are provided in the section “[OUTSTAT= Data Set](#)” on page 1554.

OUTCDF=SAS-data-set

names the output data set to contain estimates of the cumulative distribution function (CDF) value at each of the observations. The information is output for each specified model whose parameter estimation process converges. The data set also contains the estimates of the empirical distribution function (EDF). Details of the variables in this data set are provided in the section “[OUTCDF= Data Set](#)” on page 1555.

OUTMODELINFO=SAS-data-set

names the output data set to contain the status of each fitted model. The status information includes the convergence status of the optimization process that is used to estimate the parameters, the status of estimating the covariance matrix, and whether a model is the best according to the specified selection criterion. Details of the variables in this data set are provided in the section “[OUTMODELINFO= Data Set](#)” on page 1556.

INEST=SAS-data-set

names the input data set that contains the initial values of the parameter estimates to start the optimization process. The initial values specified in the INIT= option in the DIST statement take precedence over any initial values specified in this data set. Details of the variables in this data set are provided in the section “[INEST= Data Set](#)” on page 1558.

NOPRINT

turns off all displayed and graphical output. If specified, any value specified for the PRINT= and PLOTS= options is ignored.

PRINT <(global-display-option) > <=display-option >

PRINT <(global-display-option) > <=(display-options . . .) >

specifies the desired displayed output. The *display-options* are separated by spaces.

The following *global-display-option* is available:

ONLY turns off the default displayed output and displays only the requested output.

The following *display-options* are available:

ALL	displays all the output.
NONE	displays none of the output. If specified, this option overrides all the other display options. The default displayed output is also suppressed.
DESCSTATS	displays the descriptive statistics for the response variable and the regressor variables, if they are specified.
SELECTION SELECT	displays the model selection table.
ALLFITSTATS	displays the comparison of all the statistics of fit for all the models in one table. The table does not include the models whose parameter estimation process does not converge.
INITIALVALUES	displays the initial values and bounds used for estimating each model.

CONVSTATUS	displays the convergence status of the parameter estimation process.
NLOHISTORY	displays the iteration history of the nonlinear optimization process used for estimating the parameters.
NLOSUMMARY	displays the summary of the nonlinear optimization process used for estimating the parameters.
STATISTICS FITSTATS	displays the statistics of fit for each model. The statistics of fit are not displayed for models whose parameter estimation process does not converge.
ESTIMATES PARMEST	displays the final estimates of parameters. The estimates are not displayed for models whose parameter estimation process does not converge.

If the PRINT= option is not specified or the ONLY *global-display-option* is not specified, then the default displayed output is equivalent to specifying PRINT=(SELECTION CONVSTATUS NLOSUMMARY STATISTICS ESTIMATES).

PLOTS <(global-plot-options)> <=(plot-request-option)>

PLOTS <(global-plot-options)> <=(plot-request-options ...)>

specifies the desired graphical output. The *global-plot-options* and *plot-request-options* are separated by spaces.

The following *global-plot-options* are available:

ONLY	turns off the default graphical output and prepares only the requested plots.
MARKCENSORED	marks right-censored observations, if any, in the PDF and CDF plots. This option has no effect if right-censoring is not specified in the MODEL statement.
MARKTRUNCATED	marks left-truncated observations, if any, in the PDF and CDF plots. This option has no effect if left-truncation is not specified in the MODEL statement.
HISTOGRAM	plots the histogram of the response variable on the PDF plots.
KERNEL	plots the kernel estimate of the probability density of the response variable on the PDF plots.

The following *plot-request-options* are available:

ALL	displays all the graphical output.
NONE	displays none of the graphical output. If specified, this option overrides all the other plot request options. The default graphical output is also suppressed.
CDF	prepares a plot that compares the cumulative distribution function (CDF) estimates of all the candidate distribution models and the empirical distribution function (EDF) estimate. The plot does not contain CDF estimates for models whose parameter estimation process does not converge.

CDFPERDIST	prepares a plot of the CDF estimates of each candidate distribution model. A plot is not prepared for models whose parameter estimation process does not converge.
PDF	prepares a plot that compares the probability density function (PDF) estimates of all the candidate distribution models. The plot does not contain PDF estimates for models whose parameter estimation process does not converge.
PDFPERDIST	prepares a plot of the PDF estimates of each candidate distribution model. A plot is not prepared for models whose parameter estimation process does not converge.
PP	prepares the probability-probability plot (known as the P-P plot) that compares the CDF estimate of each candidate distribution model against the empirical distribution function (EDF). The data shown in this plot is used for computing the EDF-based statistics of fit.

If the PLOTS= option is not specified or the ONLY *global-plot-option* is not specified, then the default graphical output is equivalent to specifying PLOTS=(CDF PDF).

BY Statement

A BY statement can be used in the SEVERITY procedure to process the input data set in groups of observations defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in the order of the BY variables.

MODEL Statement

```
MODEL response-variable-name < (response-variable-options) > <=regressor-variable-list>
      </fit-options> ;
```

This statement specifies the name of the response variable whose distribution needs to be modeled. You can also specify additional options to indicate any truncation or censoring of the response and any regression effects in this statement.

All the analysis variables specified in this statement must be present in the input data set that is specified by using the DATA= option in the PROC SEVERITY statement. The response variable and the regressor variables are expected to have nonmissing values. If any of the variables has a missing value in an observation, then a warning is written to the SAS log and that observation is ignored.

The following *response-variable-options* can be used in the MODEL statement:

LEFTTRUNCATED | **LT=***variable-name* < (*left-truncation-options*) >

LEFTTRUNCATED | **LT=***number* < (*left-truncation-options*) >

specifies the left-truncation variable or a global left-truncation threshold.

Using the first form, you can specify a data set variable that contains the left-truncation threshold. If the value of this variable is missing or 0 for some observations, then PROC SEVERITY assumes that such observations are not left-truncated.

Alternatively, using the second form, you can specify a left-truncation threshold that applies to all the observations in the data set. This threshold must be a nonzero positive number.

It is assumed that the response variable contains the *observed* values. By definition of left-truncation, you can observe only a value that is greater than the truncation threshold. If a response variable value is less than or equal to the threshold, a warning is printed to the SAS log, and the observation is ignored. More details about left-truncation are provided in the section “[Censoring and Truncation](#)” on page 1540.

The following left-truncation option can be specified for an alternative interpretation of the left-truncation threshold:

PROBOBSERVED | **POBS=***number*

specifies the probability of observability, which is defined as the probability that the underlying severity event gets observed (and recorded) for the specified left-threshold value.

The specified number must lie in the (0.0, 1.0] interval. A value of 1.0 is equivalent to specifying that there is no left-truncation, because it means that no severity events can occur with a value less than or equal to the threshold. If you specify value of 1.0, PROC SEVERITY prints a warning to the SAS log and proceeds by assuming that LEFTTRUNCATED= option is not specified.

More details about the probability of observability are provided in the section “[Probability of Observability](#)” on page 1540.

RIGHTCENSORED | **RC=***variable-name* < (*number list*) >

RIGHTCENSORED | **RC=***number*

specifies the right-censoring variable with indicator values, or a global right-censoring limit.

Using the first form, you can specify a data set variable that contains the censoring indicator values. By default, a value of 0 for the censor indicator variable indicates that the observed value of the response variable is censored on the right. In other words, the actual value is greater than or equal to the recorded value. You can optionally specify a list of censor indicator values. If the censor indicator variable has a missing value, then that observation is treated as uncensored.

Alternatively, using the second form, you can specify a limit value for right-censoring that applies to all the observations in the data set. If the response variable value recorded for an observation is greater than or equal to the specified limit, then that observation is assumed to be censored at the limit. Otherwise, the observation is assumed to be uncensored. More details about right-censoring are provided in the section “[Censoring and Truncation](#)” on page 1540.

The following *fit-options* can be used in the MODEL statement after a slash (/):

CRITERION | CRITERIA | CRIT=*criterion-option*

specifies the model selection criterion.

If two or more models are specified for estimation, then the one with the best value for the selection criterion is chosen as the best model. If the OUTMODELINFO= data set is specified, then the best model's observation has a value of 1 for the `_SELECTED_` variable. You can specify one of the following *criterion-options*:

LOGLIKELIHOOD LL	specifies $-2 * \log(L)$ as the selection criterion, where L is the likelihood of the data. A lower value is deemed better. This is the default.
AIC	specifies the Akaike's information criterion (AIC) as the selection criterion. A lower value is deemed better.
AICC	specifies the finite-sample corrected Akaike's information criterion (AICC) as the selection criterion. A lower value is deemed better.
BIC	specifies Schwarz Bayesian information criterion (BIC) as the selection criterion. A lower value is deemed better.
KS	specifies the Kolmogorov-Smirnov (KS) statistic value, which is computed by using the empirical distribution function (EDF) estimate, as the selection criterion. A lower value is deemed better.
AD	specifies the Anderson-Darling (AD) statistic value, which is computed by using the empirical distribution function (EDF) estimate, as the selection criterion. A lower value is deemed better.
CVM	specifies the Cramér-von-Mises (CvM) statistic value, which is computed by using the empirical distribution function (EDF) estimate, as the selection criterion. A lower value is deemed better.

More details about these options are provided in the section “[Statistics of Fit](#)” on page 1549.

EMPIRICALCDF | EDF=*method*

specifies the method to use for computing the nonparametric or empirical estimate of the cumulative distribution function of the data. The following methods can be specified:

AUTOMATIC | AUTO

specifies that the method be chosen automatically based on the data specification. This option is the default. If no right-censoring or left-truncation is specified, then the standard empirical estimation method (STANDARD) is chosen. If either right-censoring or left-truncation is specified, then the Kaplan-Meier method (KAPLANMEIER) is chosen.

STANDARD | STD

specifies that the standard empirical estimation method be used. This ignores any censoring or truncation information even if specified, and can thus result in estimates that are more biased than those obtained with other methods more suitable for such data.

KAPLANMEIER | KM

specifies that the product limit estimator proposed by Kaplan and Meier (1958) be used.

MODIFIEDKM | MKM <(options)>

specifies that the modified product limit estimator be used. This method allows the estimates to be more robust by ignoring the contributions to the estimate due to small risk-set sizes. The risk set is the set of observations at the risk of failing, where an observation is said to fail if it has not been processed yet and might experience censoring or truncation. The minimum risk-set size that makes it eligible to be included in the estimation can be specified either as an absolute lower bound on the size (RSLB= option) or a relative lower bound determined by the formula cn^α proposed by Lai and Ying (1991). Values of c and α can be specified by using the C= and ALPHA= options respectively. By default, the relative lower bound is used with values of $c = 1$ and $\alpha = 0.5$. However, you can modify the default by using the following options:

RSLB=number

specifies the absolute lower bound on the risk set size to be included in the estimate.

C=number

specifies the value to use for c when the lower bound on the risk set size is defined as cn^α . This value must satisfy $c > 0$.

ALPHA | A=number

specifies the value to use for α when the lower bound on the risk set size is defined as cn^α . This value must satisfy $0 < \alpha < 1$.

More details about each of the methods are provided in the section “[Empirical Distribution Function Estimation Methods](#)” on page 1547.

DIST Statement

DIST *distribution-name* <(*distribution-options*)> ;

This statement specifies a candidate distribution to be estimated by the SEVERITY procedure. Each distribution must be specified by using a separate DIST statement. If the distribution is not a predefined distribution, then the CMPLIB= system option must be submitted with appropriate libraries prior to submitting the PROC SEVERITY step to enable the procedure to find the model functions defined with the FCMP procedure.

If no DIST statement is specified, then the SEVERITY procedure estimates all the predefined distributions for your convenience. The description of the default distributions is provided in the section “[Predefined Distribution Models](#)” on page 1530.

The following *distribution-options* can be used in the DIST statement:

INIT=(name=value ... name=value)

specifies the initial values to be used for the distribution parameters to start the parameter estimation process. The values must be specified by parameter names. The parameter names must match the names used in the model definition. For example, let a model M's definition contain a M_PDF function with following signature:

```
function M_PDF(x, alpha, beta);
```

For this model, the names **alpha** and **beta** must be used for the INIT option. The names are case-insensitive. If you do not specify initial values for some parameters in the INIT statement, then a default value of 0.001 is assumed for those parameters. If you specify an incorrect parameter, PROC SEVERITY prints a warning to the SAS log and does not fit the model. All specified values must be nonmissing.

If you are modeling regression effects, then the initial value of the first distribution parameter (**alpha** in the preceding example) should be the initial *base* value of the scale parameter or log-transformed scale parameter. More details are provided in the section “[Estimating Regression Effects](#)” on page 1543.

The use of INIT= option is one of the three methods available for initializing the parameters. You can find more details in the section “[Parameter Initialization](#)” on page 1546. If none of the initialization methods is used, then PROC SEVERITY initializes all parameters to 0.001.

NLOPTIONS Statement

NLOPTIONS *options* ;

The SEVERITY procedure uses the nonlinear optimization (NLO) subsystem to perform the nonlinear optimization of the likelihood function to obtain the estimates of distribution and regression parameters. You can use the NLOPTIONS statement to control different aspects of this optimization process. For most problems, the default settings of the optimization process are adequate. However, in some cases it might be useful to change the optimization technique or to change the maximum number of iterations. The following statement uses the MAXITER= option to set the maximum number of iterations to 200 and uses the TECH= option to change the optimization technique to the double-dogleg optimization (DBLDOG) rather than the default technique, the trust region optimization (TRUREG), used in the SEVERITY procedure:

```
nloptions tech=dbldog maxiter=200;
```

A discussion of the full range of options that can be used with the NLOPTIONS statement is given in Chapter 6, “[Nonlinear Optimization Methods](#).” The SEVERITY procedure supports all of those options except the options that are related to displaying the optimization information. You can use the PRINT= option in the PROC SEVERITY statement to request the optimization summary and iteration history.

Details: SEVERITY Procedure

Defining a Distribution Model with the FCMP Procedure

A severity *distribution model* consists of a set of functions and subroutines that are defined using the FCMP procedure. The FCMP procedure is part of Base SAS software. Each function or subroutine must be named as *<distribution-name>_<keyword>*, where *distribution-name* is the identifying short name of the distribution and *keyword* identifies one of the functions or subroutines. The total length of the name should not exceed 32. Each function or subroutine must have a specific signature, which consists of the number of arguments, sequence and types of arguments, and return value type. The summary of all the recognized function and subroutine names and their expected behavior is given in [Table 22.2](#).

Consider following points when you define a distribution model:

- When you define a function or subroutine requiring parameter arguments, the names and order of those arguments must be the same. Arguments other than the parameter arguments can have any name, but they must satisfy the requirements on their type and order.
- When the SEVERITY procedure invokes any function or subroutine, it provides the necessary input values according to the specified signature, and expects the function or subroutine to prepare the output and return it according to the specification of the return values in the signature.
- You can typically use most of the SAS programming statements and SAS functions that you can use in a DATA step for defining the FCMP functions and subroutines. However, there are a few differences in the capabilities of the DATA step and the FCMP procedure. Refer to the documentation of the FCMP procedure to learn more.
- As indicated in [Table 22.2](#), the only required functions are the PDF and the CDF functions. It is strongly recommended that you define the PARMINIT subroutine to provide a good set of initial values for the parameters. The information provided by PROC SEVERITY to the PARMINIT subroutine enables you to use popular initialization approaches based on the method of moments and the method of percentile matching, but you can implement any algorithm to initialize the parameters by using the values of the response variable and the estimate of its empirical distribution function.
- The LOWERBOUNDS subroutines should be defined if the lower bound on at least one distribution parameter is different from the default lower bound of 0. If you define a LOWERBOUNDS subroutine but do not set a lower bound for some parameter inside the subroutine, then that parameter is assumed to have no lower bound (or a lower bound of $-\infty$). Hence, it is recommended that you explicitly return the lower bound for each parameter when you define the LOWERBOUNDS subroutine.
- The UPPERBOUNDS subroutines should be defined if the upper bound on at least one distribution parameter is different from the default upper bound of ∞ . If you define an

UPPERBOUNDS subroutine but do not set an upper bound for some parameter inside the subroutine, then that parameter is assumed to have no upper bound (or a upper bound of ∞). Hence, it is recommended that you explicitly return the upper bound for each parameter when you define the UPPERBOUNDS subroutine.

- If you want to use the distribution in a model with regression effects, then make sure that the first parameter of the distribution is the scale parameter itself or a log-transformed scale parameter. If the first parameter is a log-transformed scale parameter, then you must define the SCALETRANSFORM function.
- In general, it is not necessary to define the gradient and Hessian functions for the PDF and the CDF, because PROC SEVERITY uses an internal system of evaluating their derivatives. The internal system typically computes the derivatives analytically. But, if it is unable to do so for some components of the PDF or the CDF function, then a note is written to the SAS log that finite difference approximation was used to evaluate the derivative of such components. This can especially be true if your definitions of the PDF and the CDF functions use other functions defined by you or some SAS functions that the internal system cannot differentiate analytically. PROC SEVERITY does reasonably well with these finite difference approximations. But, if you know of a way to compute the derivative of that component analytically, then you should define the gradient and Hessian functions by using the analytic method.

Table 22.2 shows functions and subroutines that define a distribution model, and subsections after the table provide more detail. The required functions are listed first, and the others are listed in alphabetical order of the keyword suffix.

Table 22.2 List of Functions and Subroutines That Define a Distribution Model

Keyword Suffix	Type	Required	Expected to Return
CDF	Function	YES	Cumulative distribution function value
PDF	Function	YES	Probability distribution function value
CDFGRADIENT	Subroutine	NO	Gradient of the CDF
CDFHESSIAN	Subroutine	NO	Hessian of the CDF
CONSTANTPARM	Subroutine	NO	Constant parameters
DESCRIPTION	Function	NO	Description of the distribution
LOWERBOUNDS	Subroutine	NO	Lower bounds on parameters
PARMINIT	Subroutine	NO	Initial values for parameters
PDFGRADIENT	Subroutine	NO	Gradient of the PDF
PDFHESSIAN	Subroutine	NO	Hessian of the PDF
SCALETRANSFORM	Function	NO	Type of relationship between the first distribution parameter and the scale parameter
UPPERBOUNDS	Subroutine	NO	Upper bounds on parameters

The signature syntax and semantics of each function or subroutine are as follows:

dist_CDF

defines a function that returns the value of the cumulative distribution function (CDF) of the distribution at the specified values of the random variable and distribution parameters.

- *Type:* Function
- *Required:* YES
- *Number of arguments:* $m + 1$, where m is the number of distribution parameters
- *Sequence and type of arguments:*
 - x Numeric value of the random variable at which the CDF value should be evaluated
 - p_1 Numeric value of the first parameter
 - p_2 Numeric value of the second parameter
 -
 - p_m Numeric value of the m th parameter
- *Return value:* Numeric value that contains the CDF value $F(x; p_1, p_2, \dots, p_m)$

If you want to consider this distribution as a candidate distribution when estimating a response variable model with regression effects, then the first parameter of this distribution must be a scale parameter or log-transformed scale parameter. In other words, if the distribution has a scale parameter, then the following equation must be satisfied:

$$F(x; p_1, p_2, \dots, p_m) = F\left(\frac{x}{p_1}; 1, p_2, \dots, p_m\right)$$

If the distribution has a log-transformed scale parameter, then the following equation must be satisfied:

$$F(x; p_1, p_2, \dots, p_m) = F\left(\frac{x}{\exp(p_1)}; 0, p_2, \dots, p_m\right)$$

Here is a sample structure of the function for a distribution named 'FOO':

```
function FOO_CDF(x, P1, P2);
  /* Code to compute CDF by using x, P1, and P2 */

  F = <computed CDF>;
  return (F);
endsub;
```

dist_PDF

defines a function that returns the value of the probability density function (PDF) of the distribution at the specified values of the random variable and distribution parameters.

- *Type:* Function
- *Required:* YES
- *Number of arguments:* $m + 1$, where m is the number of distribution parameters

- *Sequence and type of arguments:*
 - x Numeric value of the random variable at which the PDF value should be evaluated
 - p1 Numeric value of the first parameter
 - p2 Numeric value of the second parameter
 -
 - pm Numeric value of the *m*th parameter
- *Return value:* Numeric value that contains the PDF value $f(x; p_1, p_2, \dots, p_m)$

If you want to consider this distribution as a candidate distribution when estimating a response variable model with regression effects, then the first parameter of this distribution must be a scale parameter or log-transformed scale parameter. In other words, if the distribution has a scale parameter, then the following equation must be satisfied:

$$f(x; p_1, p_2, \dots, p_m) = \frac{1}{p_1} f\left(\frac{x}{p_1}; 1, p_2, \dots, p_m\right)$$

If the distribution has a log-transformed scale parameter, then the following equation must be satisfied:

$$f(x; p_1, p_2, \dots, p_m) = \frac{1}{\exp(p_1)} f\left(\frac{x}{\exp(p_1)}; 0, p_2, \dots, p_m\right)$$

Here is a sample structure of the function for a distribution named 'FOO':

```
function FOO_PDF(x, P1, P2);
  /* Code to compute PDF by using x, P1, and P2 */

  f = <computed PDF>;
  return (f);
endsub;
```

dist_CDFGRADIENT

defines a subroutine that returns the gradient vector of the CDF of the distribution at the specified values of the random variable and distribution parameters.

- *Type:* Subroutine
- *Required:* NO
- *Number of arguments:* $m + 2$, where m is the number of distribution parameters
- *Sequence and type of arguments:*
 - x Numeric value of the random variable at which the gradient of the CDF should be evaluated
 - p1 Numeric value of the first parameter
 - p2 Numeric value of the second parameter
 -
 - pm Numeric value of the *m*th parameter

`grad{*}` Output numeric array of size m that contains the gradient vector evaluated at the specified values. The expected order of the values in the array is as follows: $\frac{\partial F}{\partial p_1} \frac{\partial F}{\partial p_2} \dots \frac{\partial F}{\partial p_m}$

- *Return value:* Numeric array that contains the gradient of the CDF evaluated at x for the parameter values (p_1, p_2, \dots, p_m)

Here is a sample structure of the function for a distribution named ‘FOO’:

```
subroutine FOO_CDFGRADIENT(x, P1, P2, grad{*});
  outargs grad;

  /* Code to compute gradient by using x, P1, and P2 */
  grad[1] = <partial derivative of CDF w.r.t. P1
            evaluated at x, P1, P2>;
  grad[2] = <partial derivative of CDF w.r.t. P2
            evaluated at x, P1, P2>;
endsub;
```

dist_CDFHESSIAN

defines a subroutine that returns the Hessian matrix of the CDF of the distribution evaluated at the specified values of the random variable and distribution parameters.

- *Type:* Subroutine
- *Required:* NO
- *Number of arguments:* $m + 2$, where m is the number of distribution parameters
- *Sequence and type of arguments:*
 - x Numeric value of the random variable at which the Hessian of the CDF value should be evaluated
 - $p1$ Numeric value of the first parameter
 - $p2$ Numeric value of the second parameter
 -
 - pm Numeric value of the m th parameter
- *hess{*}* Output numeric array of size $m(m + 1)/2$ that contains the lower triangular portion of the Hessian matrix in a packed vector form, evaluated at the specified values. The expected order of the values in the array is as follows:

$$\frac{\partial^2 F}{\partial p_1^2} \mid \frac{\partial^2 F}{\partial p_1 \partial p_2} \quad \frac{\partial^2 F}{\partial p_2^2} \mid \dots \mid \frac{\partial^2 F}{\partial p_1 \partial p_m} \quad \frac{\partial^2 F}{\partial p_2 \partial p_m} \dots \frac{\partial^2 F}{\partial p_m^2}$$
- *Return value:* Numeric array that contains the lower triangular portion of the Hessian of the CDF evaluated at x for the parameter values (p_1, p_2, \dots, p_m)

Here is a sample structure of the subroutine for a distribution named ‘FOO’:

```
subroutine FOO_CDFHESSIAN(x, P1, P2, hess{*});
  outargs hess;

  /* Code to compute Hessian by using x, P1, and P2 */
  hess[1] = <second order partial derivative of CDF
           w.r.t. P1 evaluated at x, P1, P2>;
  hess[2] = <second order partial derivative of CDF
           w.r.t. P1 and P2 evaluated at x, P1, P2>;
  hess[3] = <second order partial derivative of CDF
           w.r.t. P2 evaluated at x, P1, P2>;
endsub;
```

dist_CONSTANTPARM

defines a subroutine that specifies constant parameters. A parameter is *constant* if it is required for defining a distribution but is not subject to optimization in PROC SEVERITY. Constant parameters are required to be part of the model in order to compute the PDF or the CDF of the distribution. Typically, values of these parameters are known a priori or estimated using some means other than the maximum likelihood method used by PROC SEVERITY. You can estimate them inside the *dist_PARMINIT* subroutine. Once initialized, the parameters remain constant in the context of PROC SEVERITY; that is, they retain their initial value. PROC SEVERITY estimates only the nonconstant parameters.

- *Type*: Subroutine
- *Required*: NO
- *Number of arguments*: k , where k is the number of constant parameters
- *Sequence and type of arguments*:

constant parameter 1 Name of the first constant parameter

.....

constant parameter k Name of the k th constant parameter

- *Return value*: None

Here is a sample structure of the subroutine for a distribution named ‘FOO’ that has P3 and P5 as its constant parameters, assuming that distribution has at least three parameters:

```
subroutine FOO_CONSTANTPARM(p5, p3);
endsub;
```

The following points should be noted while specifying the constant parameters:

- At least one distribution parameter must be free to be optimized; that is, if a distribution has total m parameters, then k must be strictly less than m .
- If you want to use this distribution for modeling regression effects, then the first parameter must not be a constant parameter.
- The order of arguments in the signature of this subroutine does not matter as long as each argument’s name matches the name of one of the parameters that are defined in the signature of the *dist_PDF* function.

- The constant parameters must be specified in signatures of all the functions and subroutines that accept distribution parameters as their arguments.
- You must provide a nonmissing initial value for each constant parameter by using one of the supported parameter initialization methods.

***dist_*DESCRIPTION**

defines a function that returns a description of the distribution.

- *Type*: Function
- *Required*: NO
- *Number of arguments*: None
- *Sequence and type of arguments*: Not applicable
- *Return value*: Character value containing a description of the distribution

Here is a sample structure of the function for a distribution named ‘FOO’:

```
function FOO_DESCRIPTION() $48;
  length desc $48;
  desc = "A model for a continuous distribution named foo";
  return (desc);
endsub;
```

There is no restriction on the length of the description (the length of 48 used in the previous example is for illustration purposes only). However, if the length is greater than 256, then only the first 256 characters appear in the displayed output and in the `_DESCRIPTION_` variable of the `OUTMODELINFO=` data set. Hence, the recommended length of the description is less than or equal to 256.

***dist_*LOWERBOUNDS**

defines a subroutine that returns lower bounds for the parameters of the distribution. If this subroutine is not defined for a given distribution, then the SEVERITY procedure assumes a lower bound of 0 for each parameter. If a lower bound of l_i is returned for a parameter p_i , then the SEVERITY procedure assumes that $l_i < p_i$ (strict inequality). If a missing value is returned for some parameter, then the SEVERITY procedure assumes that there is no lower bound for that parameter (equivalent to a lower bound of $-\infty$).

- *Type*: Subroutine
- *Required*: NO
- *Number of arguments*: m , where m is the number of distribution parameters
- *Sequence and type of arguments*:

p1	Output argument that returns the lower bound on the first parameter. This must be specified in the OUTARGS statement inside the subroutine’s definition.
p2	Output argument that returns the lower bound on the second parameter. This must be specified in the OUTARGS statement inside the subroutine’s definition.
.....	

pm Output argument that returns the lower bound on the *m*th parameter. This must be specified in the OUTARGS statement inside the subroutine's definition.

- *Return value:* The results, lower bounds on parameter values, should be returned in the parameter arguments of the subroutine.

Here is a sample structure of the subroutine for a distribution named 'FOO':

```
subroutine FOO_LOWERBOUNDS (p1, p2);
  outargs p1, p2;

  p1 = <lower bound for P1>;
  p2 = <lower bound for P2>;
endsub;
```

dist_PARMINIT

defines a subroutine that returns the initial values for the distribution's parameters given an empirical distribution function (EDF) estimate.

- *Type:* Subroutine
- *Required:* NO
- *Number of arguments:* $m + 4$, where m is the number of distribution parameters
- *Sequence and type of arguments:*

dim Input numeric value that contains the dimension of the *x*, *nx*, and *F* array arguments

x{}* Input numeric array of dimension *dim* that contains values of the random variables at which the EDF estimate is available. It can be assumed that *x* contains values in an increasing order. In other words, if $i < j$, then $x[i] < x[j]$.

nx{}* Input numeric array of dimension *dim*. Each $nx[i]$ contains the number of observations in the original data that have the value $x[i]$.

F{}* Input numeric array of dimension *dim*. Each $F[i]$ contains the EDF estimate for $x[i]$. This estimate is computed by the SEVERITY procedure based on the `EMPIRICALCDF=` option.

p1 Output argument that returns the initial value of the first parameter. This must be specified in the OUTARGS statement inside the subroutine's definition.

p2 Output argument that returns the initial value of the second parameter. This must be specified in the OUTARGS statement inside the subroutine's definition.

.....

pm Output argument that returns the initial value of the *m*th parameter. This must be specified in the OUTARGS statement inside the subroutine's definition.

- *Return value:* The results, initial values of the parameters, should be returned in the parameter arguments of the subroutine.

Here is a sample structure of the subroutine for a distribution named 'FOO':

```
subroutine FOO_PARMINIT(dim, x{*}, nx{*}, F{*}, p1, p2);
  outargs p1, p2;

  /* Code to initialize values of P1 and P2 by using
     dim, x, nx, and F */

  p1 = <initial value for p1>;
  p2 = <initial value for p2>;
endsub;
```

dist_PDFGRADIENT

defines a subroutine that returns the gradient vector of the PDF of the distribution at the specified values of the random variable and distribution parameters.

- *Type:* Subroutine
- *Required:* NO
- *Number of arguments:* $m + 2$, where m is the number of distribution parameters
- *Sequence and type of arguments:*

x	Numeric value of the random variable at which the gradient of the PDF should be evaluated
p1	Numeric value of the first parameter
p2	Numeric value of the second parameter
....	
pm	Numeric value of the m th parameter
grad{*}	Output numeric array of size m that contains the gradient vector evaluated at the specified values. The expected order of the values in the array is as follows: $\frac{\partial f}{\partial p_1} \frac{\partial f}{\partial p_2} \dots \frac{\partial f}{\partial p_m}$
- *Return value:* Numeric array that contains the gradient of the PDF evaluated at x for the parameter values (p_1, p_2, \dots, p_m)

Here is a sample structure of the function for a distribution named 'FOO':

```
subroutine FOO_PDFGRADIENT(x, P1, P2, grad{*});
  outargs grad;

  /* Code to compute gradient by using x, P1, and P2 */
  grad[1] = <partial derivative of PDF w.r.t. P1
             evaluated at x, P1, P2>;
  grad[2] = <partial derivative of PDF w.r.t. P2
             evaluated at x, P1, P2>;
endsub;
```

dist_PDFHESSIAN

defines a subroutine that returns the Hessian matrix of the PDF of the distribution evaluated at the specified values of the random variable and distribution parameters.

- *Type:* Subroutine
- *Required:* NO
- *Number of arguments:* $m + 2$, where m is the number of distribution parameters
- *Sequence and type of arguments:*

x	Numeric value of the random variable at which the Hessian of the PDF should be evaluated
$p1$	Numeric value of the first parameter
$p2$	Numeric value of the second parameter
.....	
pm	Numeric value of the m th parameter
$hess\{*\}$	Output numeric array of size $m(m + 1)/2$ that contains the lower triangular portion of the Hessian matrix in a packed vector form, evaluated at the specified values. The expected order of the values in the array is as follows: $\frac{\partial^2 f}{\partial p_1^2} \mid \frac{\partial^2 f}{\partial p_1 \partial p_2} \quad \frac{\partial^2 f}{\partial p_2^2} \mid \cdots \mid \frac{\partial^2 f}{\partial p_1 \partial p_m} \quad \frac{\partial^2 f}{\partial p_2 \partial p_m} \cdots \frac{\partial^2 f}{\partial p_m^2}$
- *Return value:* Numeric array that contains the lower triangular portion of the Hessian of the PDF evaluated at x for the parameter values (p_1, p_2, \dots, p_m)

Here is a sample structure of the subroutine for a distribution named 'FOO':

```
subroutine FOO_PDFHESSIAN(x, P1, P2, hess{*});
  outargs hess;

  /* Code to compute Hessian by using x, P1, and P2 */
  hess[1] = <second order partial derivative of PDF
            w.r.t. P1 evaluated at x, P1, P2>;
  hess[2] = <second order partial derivative of PDF
            w.r.t. P1 and P2 evaluated at x, P1, P2>;
  hess[3] = <second order partial derivative of PDF
            w.r.t. P2 evaluated at x, P1, P2>;
endsub;
```

dist_SCALETRANSFORM

defines a function that returns a keyword to identify the transform that needs to be applied to the scale parameter to convert it to the first parameter of the distribution.

If you want to use this distribution for modeling regression effects, then the first parameter of this distribution must be a scale parameter. However, for some distributions, a typical or convenient parameterization might not have a scale parameter, but one of the parameters can be a simple transform of the scale parameter. As an example, consider a typical parameterization of the lognormal distribution with two parameters, location μ and shape σ , for which the PDF is defined as follows:

$$f(x; \mu, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{\log(x)-\mu}{\sigma}\right)^2}$$

You can reparameterize this distribution to contain a parameter θ instead of the parameter μ such that $\mu = \log(\theta)$. The parameter θ would then be a scale parameter. However, if you want to specify the distribution in terms of μ and σ (which is a more recognized form of the lognormal distribution) and still allow it as a candidate distribution for estimating regression effects, then instead of writing another distribution with parameters θ and σ , you can simply define the distribution with μ as the first parameter and specify that it is the logarithm of the scale parameter.

- *Type*: Function
- *Required*: NO
- *Number of arguments*: None
- *Sequence and type of arguments*: Not applicable
- *Return value*: Character value that contains one of the following keywords:

LOG	specifies that the first parameter is the logarithm of the scale parameter.
IDENTITY	specifies that the first parameter is a scale parameter without any transformation.

If this function is not specified, then the IDENTITY transform is assumed.

Here is a sample structure of the function for a distribution named 'FOO':

```
function FOO_SCALETRANSFORM() $8;
  length xform $8;
  xform = "IDENTITY";
  return (xform);
endsub;
```

dist_UPPERBOUNDS

defines a subroutine that returns upper bounds for the parameters of the distribution. If this subroutine is not defined for a given distribution, then the SEVERITY procedure assumes that there is no upper bound for any of the parameters. If an upper bound of u_i is returned for a parameter p_i , then the SEVERITY procedure assumes that $p_i < u_i$ (strict inequality). If a missing value is returned for some parameter, then the SEVERITY procedure assumes that there is no upper bound for that parameter (equivalent to an upper bound of ∞).

- *Type*: Subroutine
- *Required*: NO
- *Number of arguments*: m , where m is the number of distribution parameters
- *Sequence and type of arguments*:

p1	Output argument that returns the upper bound on the first parameter. This must be specified in the OUTARGS statement inside the subroutine's definition.
p2	Output argument that returns the upper bound on the second parameter. This must be specified in the OUTARGS statement inside the subroutine's definition.
.....	

pm Output argument that returns the upper bound on the *m*th parameter. This must be specified in the OUTARGS statement inside the subroutine's definition.

- *Return value*: The results, upper bounds on parameter values, should be returned in the parameter arguments of the subroutine.

Here is a sample structure of the subroutine for a distribution named 'FOO':

```
subroutine FOO_UPPERBOUNDS(p1, p2);
  outargs p1, p2;

  p1 = <upper bound for P1>;
  p2 = <upper bound for P2>;
endsub;
```

Predefined Distribution Models

A set of predefined distribution models is provided with the SEVERITY procedure. A summary of the models is provided in Table 22.3. For each distribution model, the table lists the parameters in the order in which they appear in the signature of the functions or subroutines that accept distribution parameters as input or output arguments. The table also mentions the bounds on the parameters. If the bounds are different from their default values, then the distribution model contains appropriately defined *name_LOWERBOUNDS* or *name_UPPERBOUNDS* subroutines.

All the predefined distribution models, except LOGN, are parameterized such that their first parameter is the scale parameter. For LOGN, the first parameter μ is a log-transformed scale parameter, which is specified by using the LOGN_SCALETRANSFORM subroutine. The presence of scale parameter enables you to use any of the predefined distributions as a candidate for estimating regression effects.

If you need to use the functions or subroutines defined in the predefined distributions in SAS statements other than the PROC SEVERITY step (such as in a DATA step), then they are available to you in the SASHELP.SVRTDIST library. Specify the library by using the OPTIONS global statement to set the CMPLIB= system option prior to using these functions. Note that you do not need to use the CMPLIB= option in order to use the predefined distributions with PROC SEVERITY.

Table 22.3 Predefined SEVERITY Distributions

Name	Distribution	Parameters	PDF (f) and CDF (F)
BURR	Burr	$\theta > 0, \alpha > 0,$ $\gamma > 0$	$f(x) = \frac{\alpha \gamma z^\gamma}{x(1+z^\gamma)^{(\alpha+1)}}$ $F(x) = 1 - \left(\frac{1}{1+z^\gamma}\right)^\alpha$
EXP	Exponential	$\theta > 0$	$f(x) = \frac{1}{\theta} e^{-z}$ $F(x) = 1 - e^{-z}$
GAMMA	Gamma	$\theta > 0, \alpha > 0$	$f(x) = \frac{z^\alpha e^{-z}}{x \Gamma(\alpha)}$ $F(x) = \frac{\gamma(\alpha, z)}{\Gamma(\alpha)}$
GPD	Generalized Pareto	$\theta > 0, \xi > 0$	$f(x) = \frac{1}{\theta} (1 + \xi z)^{-1-1/\xi}$ $F(x) = 1 - (1 + \xi z)^{-1/\xi}$
IGAUSS	Inverse Gaussian (Wald)	$\theta > 0, \alpha > 0$	$f(x) = \frac{1}{\theta} \sqrt{\frac{\alpha}{2\pi z^3}} e^{-\frac{\alpha(z-1)^2}{2z}}$ $F(x) = \Phi\left((z-1)\sqrt{\frac{\alpha}{z}}\right) + \Phi\left(-(z+1)\sqrt{\frac{\alpha}{z}}\right) e^{-2\alpha}$
LOGN	Lognormal	μ (no bounds), $\sigma > 0$	$f(x) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{\log(x)-\mu}{\sigma}\right)^2}$ $F(x) = \Phi\left(\frac{\log(x)-\mu}{\sigma}\right)$
PARETO	Pareto	$\theta > 0, \alpha > 0$	$f(x) = \frac{\alpha\theta^\alpha}{(x+\theta)^{\alpha+1}}$ $F(x) = 1 - \left(\frac{\theta}{x+\theta}\right)^\alpha$
WEIBULL	Weibull	$\theta > 0, \tau > 0$	$f(x) = \frac{1}{x} \tau z^\tau e^{-z^\tau}$ $F(x) = 1 - e^{-z^\tau}$

Notes:

1. $z = x/\theta$, wherever z is used.
2. θ denotes the scale parameter for all the distributions. For LOGN, $\log(\theta) = \mu$.
3. Parameters are listed in the order in which they are defined in the distribution model.
4. $\gamma(a, b) = \int_0^b t^{a-1} e^{-t} dt$ is the lower incomplete gamma function.
5. $\Phi(y) = \frac{1}{2} \left(1 + \operatorname{erf}\left(\frac{y}{\sqrt{2}}\right)\right)$ is the standard normal CDF.

Parameter Initialization for Predefined Distribution Models

The definition of each distribution model also contains a *name_PARMINIT* subroutine to initialize the parameters. The parameters are initialized by using the method of moments for all the distributions, except for the gamma and the Weibull distributions. For the gamma distribution, approximate maximum likelihood estimates are used. For the Weibull distribution, the method of percentile matching is used.

Given n observations of the severity value y_i ($1 \leq i \leq n$), the estimate of k th raw moment is denoted by m_k and computed as

$$m_k = \frac{1}{n} \sum_{i=1}^n y_i^k$$

The 100 p th percentile is denoted by π_p ($0 \leq p \leq 1$). By definition, π_p satisfies

$$F(\pi_{p-}) \leq p \leq F(\pi_p)$$

where $F(\pi_{p-}) = \lim_{h \downarrow 0} F(\pi_p - h)$. PROC SEVERITY uses the following practical method of computing π_p . Let $\hat{F}(y)$ denote the empirical distribution function (EDF) estimate at a severity value y . This estimate is computed by PROC SEVERITY and supplied to the `name_PARMINIT` subroutine. Let y_p^- and y_p^+ denote two consecutive values in the array of y values such that $\hat{F}(y_p^-) < p$ and $\hat{F}(y_p^+) \geq p$. Then, the estimate $\hat{\pi}_p$ is computed as

$$\hat{\pi}_p = y_p^- + \frac{p - \hat{F}_p^-}{\hat{F}_p^+ - \hat{F}_p^-} (y_p^+ - y_p^-)$$

where $\hat{F}_p^+ = \hat{F}(y_p^+)$ and $\hat{F}_p^- = \hat{F}(y_p^-)$.

Let ϵ denote the smallest double-precision floating-point number such that $1 + \epsilon > 1$. This machine precision constant can be obtained by using the `CONSTANT` function in Base SAS software.

The details of how parameters are initialized for each predefined distribution model are as follows:

BURR The parameters are initialized by using the method of moments. The k th raw moment of the Burr distribution is:

$$E[X^k] = \frac{\theta^k \Gamma(1 + k/\gamma) \Gamma(\alpha - k/\gamma)}{\Gamma(\alpha)}, \quad -\gamma < k < \alpha\gamma$$

Three moment equations $E[X^k] = m_k$ ($k = 1, 2, 3$) need to be solved for initializing the three parameters of the distribution. In order to get an approximate closed form solution, the second shape parameter $\hat{\gamma}$ is initialized to a value of 2. If $2m_3 - 3m_1m_2 > 0$, then simplifying and solving the moment equations yields the following feasible set of initial values:

$$\hat{\theta} = \sqrt{\frac{m_2 m_3}{2m_3 - 3m_1 m_2}}, \quad \hat{\alpha} = 1 + \frac{m_3}{2m_3 - 3m_1 m_2}, \quad \hat{\gamma} = 2$$

If $2m_3 - 3m_1m_2 < \epsilon$, then the parameters are initialized as follows:

$$\hat{\theta} = \sqrt{m_2}, \quad \hat{\alpha} = 2, \quad \hat{\gamma} = 2$$

EXP The parameters are initialized by using the method of moments. The k th raw moment of the exponential distribution is:

$$E[X^k] = \theta^k \Gamma(k + 1), \quad k > -1$$

Solving $E[X] = m_1$ yields the initial value of $\hat{\theta} = m_1$.

GAMMA The parameter α is initialized by using its *approximate* maximum likelihood (ML) estimate. For a set of n iid observations y_i ($1 \leq i \leq n$), drawn from a gamma distribution, the log likelihood, l , is defined as follows:

$$\begin{aligned}
 l &= \sum_{i=1}^n \log \left(y_i^{\alpha-1} \frac{e^{-y_i/\theta}}{\theta^\alpha \Gamma(\alpha)} \right) \\
 &= (\alpha - 1) \sum_{i=1}^n \log(y_i) - \frac{1}{\theta} \sum_{i=1}^n y_i - n\alpha \log(\theta) - n \log(\Gamma(\alpha))
 \end{aligned}$$

Using a shorter notation of \sum to denote $\sum_{i=1}^n$ and solving the equation $\partial l / \partial \theta = 0$ yields the following ML estimate of θ :

$$\hat{\theta} = \frac{\sum y_i}{n\alpha} = \frac{m_1}{\alpha}$$

Substituting this estimate in the expression of l and simplifying gives

$$l = (\alpha - 1) \sum \log(y_i) - n\alpha - n\alpha \log(m_1) + n\alpha \log(\alpha) - n \log(\Gamma(\alpha))$$

Let d be defined as follows:

$$d = \log(m_1) - \frac{1}{n} \sum \log(y_i)$$

Solving the equation $\partial l / \partial \alpha = 0$ yields the following expression in terms of the digamma function, $\psi(\alpha)$:

$$\log(\alpha) - \psi(\alpha) = d$$

The digamma function can be approximated as follows:

$$\hat{\psi}(\alpha) \approx \log(\alpha) - \frac{1}{\alpha} \left(0.5 + \frac{1}{12\alpha + 2} \right)$$

This approximation is within 1.4% of the true value for all the values of $\alpha > 0$ except when α is arbitrarily close to the positive root of the digamma function (which is approximately 1.461632). Even for the values of α that are close to the positive root, the absolute error between true and approximate values is still acceptable ($|\hat{\psi}(\alpha) - \psi(\alpha)| < 0.005$ for $\alpha > 1.07$). Solving the equation that arises from this approximation yields the following estimate of α :

$$\hat{\alpha} = \frac{3 - d + \sqrt{(d - 3)^2 + 24d}}{12d}$$

If this approximate ML estimate is infeasible, then the method of moments is used. The k th raw moment of the gamma distribution is:

$$E[X^k] = \theta^k \frac{\Gamma(\alpha + k)}{\Gamma(\alpha)}, \quad k > -\alpha$$

Solving $E[X] = m_1$ and $E[X^2] = m_2$ yields the following initial value for α :

$$\hat{\alpha} = \frac{m_1^2}{m_2 - m_1^2}$$

If $m_2 - m_1^2 < \epsilon$ (almost zero sample variance), then α is initialized as follows:

$$\hat{\alpha} = 1$$

After computing the estimate of α , the estimate of θ is computed as follows:

$$\hat{\theta} = \frac{m_1}{\hat{\alpha}}$$

Both the maximum likelihood method and the method of moments arrive at the same relationship between $\hat{\alpha}$ and $\hat{\theta}$.

GPD

The parameters are initialized by using the method of moments. Notice that for $\xi > 0$, the CDF of the generalized Pareto distribution (GPD) is:

$$\begin{aligned} F(x) &= 1 - \left(1 + \frac{\xi x}{\theta}\right)^{-1/\xi} \\ &= 1 - \left(\frac{\theta/\xi}{x + \theta/\xi}\right)^{1/\xi} \end{aligned}$$

This is equivalent to a Pareto distribution with scale parameter $\theta_1 = \theta/\xi$ and shape parameter $\alpha = 1/\xi$. Using this relationship, the parameter initialization method used for the PARETO distribution model is used to get the following initial values for the parameters of the GPD distribution model:

$$\hat{\theta} = \frac{m_1 m_2}{2(m_2 - m_1^2)}, \quad \hat{\xi} = \frac{m_2 - 2m_1^2}{2(m_2 - m_1^2)}$$

If $m_2 - m_1^2 < \epsilon$ (almost zero sample variance) or $m_2 - 2m_1^2 < \epsilon$, then the parameters are initialized as follows:

$$\hat{\theta} = \frac{m_1}{2}, \quad \hat{\xi} = \frac{1}{2}$$

IGAUSS

The parameters are initialized by using the method of moments. Note that the standard parameterization of the inverse Gaussian distribution (also known as the Wald distribution), in terms of the location parameter μ and shape parameter λ , is as follows (Klugman, Panjer, and Willmot 1998, p. 583):

$$\begin{aligned} f(x) &= \sqrt{\frac{\lambda}{2\pi x^3}} \exp\left(\frac{-\lambda(x - \mu)^2}{2\mu^2 x}\right) \\ F(x) &= \Phi\left(\left(\frac{x}{\mu} - 1\right) \sqrt{\frac{\lambda}{x}}\right) + \Phi\left(-\left(\frac{x}{\mu} + 1\right) \sqrt{\frac{\lambda}{x}}\right) \exp\left(\frac{2\lambda}{\mu}\right) \end{aligned}$$

For this parameterization, it is known that the mean is $E[X] = \mu$ and the variance is $Var[X] = \mu^3/\lambda$, which yields the second raw moment as $E[X^2] = \mu^2(1 + \mu/\lambda)$ (computed by using $E[X^2] = Var[X] + (E[X])^2$).

The predefined IGAUSS distribution model in PROC SEVERITY uses the following alternate parameterization to allow the distribution to have a scale parameter, θ :

$$\begin{aligned} f(x) &= \sqrt{\frac{\alpha\theta}{2\pi x^3}} \exp\left(\frac{-\alpha(x - \theta)^2}{2x\theta}\right) \\ F(x) &= \Phi\left(\left(\frac{x}{\theta} - 1\right) \sqrt{\frac{\alpha\theta}{x}}\right) + \Phi\left(-\left(\frac{x}{\theta} + 1\right) \sqrt{\frac{\alpha\theta}{x}}\right) \exp(2\alpha) \end{aligned}$$

The parameters θ (scale) and α (shape) of this alternate form are related to the parameters μ and λ of the preceding form such that $\theta = \mu$ and $\alpha = \lambda/\mu$. Using this relationship, the first and second raw moments of the IGAUSS distribution are:

$$E[X] = \theta$$

$$E[X^2] = \theta^2 \left(1 + \frac{1}{\alpha} \right)$$

Solving $E[X] = m_1$ and $E[X^2] = m_2$ yields the following initial values:

$$\hat{\theta} = m_1, \quad \hat{\alpha} = \frac{m_1^2}{m_2 - m_1^2}$$

If $m_2 - m_1^2 < \epsilon$ (almost zero sample variance), then the parameters are initialized as follows:

$$\hat{\theta} = m_1, \quad \hat{\alpha} = 1$$

LOGN

The parameters are initialized by using the method of moments. The k th raw moment of the lognormal distribution is:

$$E[X^k] = \exp \left(k\mu + \frac{k^2\sigma^2}{2} \right)$$

Solving $E[X] = m_1$ and $E[X^2] = m_2$ yields the following initial values:

$$\hat{\mu} = 2 \log(m_1) - \frac{\log(m_2)}{2}, \quad \hat{\sigma} = \sqrt{\log(m_2) - 2 \log(m_1)}$$

PARETO

The parameters are initialized by using the method of moments. The k th raw moment of the Pareto distribution is:

$$E[X^k] = \frac{\theta^k \Gamma(k+1) \Gamma(\alpha-k)}{\Gamma(\alpha)}, \quad -1 < k < \alpha$$

Solving $E[X] = m_1$ and $E[X^2] = m_2$ yields the following initial values:

$$\hat{\theta} = \frac{m_1 m_2}{m_2 - 2m_1^2}, \quad \hat{\alpha} = \frac{2(m_2 - m_1^2)}{m_2 - 2m_1^2}$$

If $m_2 - m_1^2 < \epsilon$ (almost zero sample variance) or $m_2 - 2m_1^2 < \epsilon$, then the parameters are initialized as follows:

$$\hat{\theta} = m_1, \quad \hat{\alpha} = 2$$

WEIBULL

The parameters are initialized by using the percentile matching method. Let q_1 and q_3 denote the estimates of the 25th and 75th percentiles, respectively. Using the formula for the CDF of Weibull distribution, they can be written as

$$1 - \exp(-(q_1/\theta)^\tau) = 0.25$$

$$1 - \exp(-(q_3/\theta)^\tau) = 0.75$$

Simplifying and solving these two equations yields the following initial values:

$$\hat{\theta} = \exp\left(\frac{r \log(q1) - \log(q3)}{r - 1}\right), \quad \hat{\tau} = \frac{\log(\log(4))}{\log(q3) - \log(\hat{\theta})}$$

where $r = \log(\log(4))/\log(\log(4/3))$. These initial values agree with those suggested in Klugman, Panjer, and Willmot (1998).

A summary of the initial values of all the parameters for all the predefined distributions is given in Table 22.4. The table also provides the names of the parameters to use in the INIT= option in the DIST statement if you want to provide a different initial value.

Table 22.4 Parameter Initialization for Predefined Distributions

Distribution	Parameter	Name for INIT option	Default Initial Value
BURR	θ	theta	$\sqrt{\frac{m_2 m_3}{2m_3 - 3m_1 m_2}}$
	α	alpha	$1 + \frac{m_3}{2m_3 - 3m_1 m_2}$
	γ	gamma	2
EXP	θ	theta	m_1
GAMMA	θ	theta	m_1/α
	α	alpha	$\frac{3-d + \sqrt{(d-3)^2 + 24d}}{12d}$
GPD	θ	theta	$m_1 m_2 / (2(m_2 - m_1^2))$
	ξ	xi	$(m_2 - 2m_1^2) / (2(m_2 - m_1^2))$
IGAUSS	θ	theta	m_1
	α	alpha	$m_1^2 / (m_2 - m_1^2)$
LOGN	μ	mu	$2 \log(m_1) - \log(m_2) / 2$
	σ	sigma	$\sqrt{\log(m_2) - 2 \log(m_1)}$
PARETO	θ	theta	$m_1 m_2 / (m_2 - 2m_1^2)$
	α	alpha	$2(m_2 - m_1^2) / (m_2 - 2m_1^2)$
WEIBULL	θ	theta	$\exp\left(\frac{r \log(q1) - \log(q3)}{r-1}\right)$
	τ	tau	$\log(\log(4)) / (\log(q3) - \log(\hat{\theta}))$

Notes:

- m_k denotes the k th raw moment
- $d = \log(m_1) - (\sum \log(y_i)) / n$
- $q1$ and $q3$ denote the 25th and 75th percentiles, respectively
- $r = \log(\log(4)) / \log(\log(4/3))$

Predefined Utility Functions

The following predefined utility functions are provided with the SEVERITY procedure and are available in the SASHELP.SVRTDIST library:

SVRTUTIL_HILLCUTOFF:

This function computes an estimate of the value where the right tail of a distribution is expected to begin. The function implements the algorithm described in Danielsson et al. 2001. The description of the algorithm uses the following notation:

n	number of observations in the original sample
B	number of bootstrap samples to draw
m_1	size of the bootstrap sample in the first step of the algorithm ($m_1 < n$)
$x_{(i)}^{j,m}$	i th order statistic of j th bootstrap sample of size m ($1 \leq i \leq m, 1 \leq j \leq B$)
$x_{(i)}$	i th order statistic of the original sample ($1 \leq i \leq n$)

Given the input sample x and values of B and m_1 , the steps of the algorithm are as follows:

1. Take B bootstrap samples of size m_1 from the original sample.
2. Find the integer k_1 that minimizes the bootstrap estimate of the mean squared error:

$$k_1 = \arg \min_{1 \leq k < m_1} Q(m_1, k)$$

3. Take B bootstrap samples of size $m_2 = m_1^2/n$ from the original sample.
4. Find the integer k_2 that minimizes the bootstrap estimate of the mean squared error:

$$k_2 = \arg \min_{1 \leq k < m_2} Q(m_2, k)$$

5. Compute the integer k_{opt} , which is used for computing the cutoff point:

$$k_{\text{opt}} = \frac{k_1^2}{k_2} \left(\frac{\log(k_1)}{2 \log(m_1) - \log(k_1)} \right)^{2 - 2 \log(k_1) / \log(m_1)}$$

6. Set the cutoff point equal to $x_{(k_{\text{opt}}+1)}$.

The bootstrap estimate of the mean squared error is computed as

$$Q(m, k) = \frac{1}{B} \sum_{j=1}^B \text{MSE}_j(m, k)$$

The mean squared error of j th bootstrap sample is computed as

$$\text{MSE}_j(m, k) = (M_j(m, k) - 2(\gamma_j(m, k))^2)^2$$

where $M_j(m, k)$ is a control variate proposed by Danielsson et al. 2001,

$$M_j(m, k) = \frac{1}{k} \sum_{i=1}^k \left(\log(x_{(m-i+1)}^{j,m}) - \log(x_{(m-k)}^{j,m}) \right)^2$$

and $\gamma_j(m, k)$ is the Hill's estimator of the tail index (Hill 1975),

$$\gamma_j(m, k) = \frac{1}{k} \sum_{i=1}^k \log(x_{(m-i+1)}^{j,m}) - \log(x_{(m-k)}^{j,m})$$

This algorithm has two tuning parameters, B and m_1 . The number of bootstrap samples B is chosen based on the availability of computational resources. The optimal value of m_1 is chosen such that the following ratio, $R(m_1)$, is minimized:

$$R(m_1) = \frac{(Q(m_1, k_1))^2}{Q(m_2, k_2)}$$

The SVRTUTIL_HILLCUTOFF utility function implements the preceding algorithm. It uses the grid search method to compute the optimal value of m_1 .

- *Type:* Function
- *Signature:* SVRTUTIL_HILLCUTOFF(n, x{*}, b, s, status)
- *Argument Description:*

n	Dimension of the array x .
x{*}	Input numeric array of dimension n that contains the sample.
b	Number of bootstrap samples used to estimate the mean squared error. If b is less than 10, then a default value of 50 is used.
s	Approximate number of steps used to search the optimal value of m_1 in the range $[n^{0.75}, n - 1]$. If s is less than or equal to 1, then a default value of 10 is used.
status	Output argument that contains the status of the algorithm. If the algorithm succeeds in computing a valid cutoff point, then <i>status</i> is set to 0. If the algorithm fails, then <i>status</i> is set to 1.
- *Return value:* The cutoff value where the right tail is estimated to start. If the size of the input sample is inadequate ($n \leq 5$), then a missing value is returned and *status* is set to a missing value. If the algorithm fails to estimate a valid cutoff value (*status* = 1), then the fifth largest value in the input sample is returned.

SVRTUTIL_PERCENTILE:

This function computes the specified percentile given the EDF estimates of a sample. Let $F(x)$ denote the EDF estimate at x . Let x_p^- and x_p^+ denote two consecutive values in the sample of x values such that $F(x_p^-) < p$ and $F(x_p^+) \geq p$. Then, the function computes the 100 p th percentile π_p as

$$\pi_p = x_p^- + \frac{p - F_p^-}{F_p^+ - F_p^-} (x_p^+ - x_p^-)$$

where $F_p^+ = F(x_p^+)$ and $F_p^- = F(x_p^-)$.

- *Type:* Function
- *Signature:* SVRTUTIL_PERCENTILE(p, n, x{*}, F{*})

- *Argument Description:*
 - p* Desired percentile. The value must be in the interval (0,1). The function returns the 100*p*th percentile.
 - n* Dimension of the *x* and *F* input arrays.
 - x{*}* Input numeric array of dimension *n* that contains distinct values of the random variable observed in the sample. These values must be sorted in increasing order.
 - F{*}* Input numeric array of dimension *n* in which each *F[i]* contains the EDF estimate for *x[i]*. These values must be sorted in nondecreasing order.
- *Return value:* The 100*p*th percentile of the input sample.

SVRTUTIL_RAWMOMENTS:

This subroutine computes the raw moments of a sample.

- *Type:* Subroutine
- *Signature:* SVRTUTIL_RAWMOMENTS(*n*, *x{*}*, *nx{*}*, *nRaw*, *raw{*}*)
- *Argument Description:*
 - n* Dimension of the *x* and *nx* input arrays.
 - x{*}* Input numeric array of dimension *n* that contains distinct values of the random variable that are observed in the sample.
 - nx{*}* Input numeric array of dimension *n* in which each *nx[i]* contains the number of observations in the sample that have the value *x[i]*.
 - nRaw* Desired number of raw moments. The output array *raw* contains the first *nRaw* raw moments.
 - raw{*}* Output array of raw moments. The *k*th element in the array (*raw{k}*) contains the *k*th raw moment, where $1 \leq k \leq nRaw$.
- *Return value:* Numeric array *raw* that contains the first *nRaw* raw moments. The array contains missing values if the sample has no observations (that is, if all the values in the *nx* array add up to zero).

SVRTUTIL_SORT:

This function sorts the given array of numeric values in an ascending or descending order.

- *Type:* Subroutine
- *Signature:* SVRTUTIL_SORT(*n*, *x{*}*, *flag*)
- *Argument Description:*
 - n* Dimension of the input array *x*.
 - x{*}* Numeric array that contains the values to be sorted at input. The subroutine uses the same array to return the sorted values.
 - flag* A numeric value that controls the sort order. If *flag* is 0, then the values are sorted in an ascending order. If *flag* has any value other than 0, then the values are sorted in descending order.
- *Return value:* Numeric array *x*, which is sorted in place (that is, the sorted array is stored in the same storage area occupied by the input array *x*).

Censoring and Truncation

One of the key features of PROC SEVERITY is that it enables you to specify whether the severity event's magnitude is observable and if it is observable, then whether the exact value of the magnitude is known. If an event is unobservable when the magnitude is in certain intervals, then it is referred to as a truncation effect. If the exact magnitude of the event is not known, but it is known to have a value in a certain interval, then it is referred to as a censoring effect.

PROC SEVERITY allows a severity event to be left-truncated and right-censored. An event is said to be left-truncated if it is observed only when $Y > T$, where Y denotes the random variable for the magnitude and T denotes a random variable for the truncation threshold. An event is said to be right-censored if it is known that the magnitude is $Y > C$, but the exact value of Y is not known. C is a random variable for the censoring limit.

PROC SEVERITY assumes that the input data is given as a triplet (y_i, t_i, δ_i) , $(i = 1, \dots, N)$, where N is the number of observations (in a BY group), y_i is the *observed* value (magnitude) of the response (event) variable, t_i is the left-truncation threshold, and δ_i is a right-censoring indicator. If δ_i is equal to one of the values specified in the RIGHTCENSORED= option (or 0 if no indicator value is specified), then it indicates that y_i is right-censored. In that case, the censoring limit c_i is assumed to be equal to the recorded value y_i . If δ_i is not equal to one of the indicator values or has a missing value, then y_i is assumed to be the exact event value; that is, the observation is uncensored.

If the global left-truncation threshold T_g is specified by using the LEFTTRUNCATED= option, then $t_i = T_g, \forall i$. If $y_i \leq t_i$ for some i , then that observation is ignored and a warning is written to the SAS log. A missing value for t_i indicates that the observation is not left-truncated.

If the global right-censoring limit C_g is specified by using the RIGHTCENSORED= option, then y_i is compared with C_g . If $y_i < C_g$, then $\delta_i = 1$ to indicate exact (uncensored) observation; otherwise, $\delta_i = 0$ to indicate right-censored observation. Note that the case of $y_i = C_g$ is considered as right-censored, because it is assumed that the actual event magnitude is greater than C_g . However, it gets recorded as C_g . If $y_i > C_g$ for some observation, then it is reduced to the limit ($y_i = C_g$) and a warning is written to the SAS log.

Specification of right-censoring and left-truncation affects the likelihood of the data (see the section “Likelihood Function” on page 1541) and how the empirical distribution function (EDF) is estimated (see the section “Empirical Distribution Function Estimation Methods” on page 1547).

Probability of Observability

For left-truncated data, PROC SEVERITY also enables you to provide additional information in the form of *probability of observability* by using the PROBOBSERVED= option. It is defined as the probability that the underlying severity event gets observed (and recorded) for the specified left-truncation threshold value. For example, if you specify a value of 0.75, then for every 75 observations recorded above a specified threshold, 25 more events have happened with a severity value less than or equal to the specified threshold. Although the exact severity value of those 25 events is not known, PROC SEVERITY can use the information about the number of those events.

In particular, for each left-truncated observation, PROC SEVERITY assumes a presence of $(1 - p)/p$ additional observations with $y_i = t_i$. These additional observations are then used for computing the likelihood (see the section “Probability of Observability and Likelihood” on page 1542) and an unconditional estimate of the empirical distribution function (see the section “EDF Estimates and Left-Truncation” on page 1549).

Parameter Estimation Method

PROC SEVERITY uses the maximum likelihood (ML) method to estimate the parameters of each model. A nonlinear optimization process is used to maximize the log of the likelihood function.

Likelihood Function

Let Y denote the random response variable, and let y denote its value recorded in an observation in the input data set. Let δ denote the censoring indicator: $\delta = 1$ indicates that the observation is uncensored (sometimes referred to as an *event* observation) and $\delta = 0$ indicates that the observation is right-censored. When $\delta = 0$, the recorded value of y is assumed to be the censoring limit, denoted by c . Let t denote the left-truncation threshold. Let $f_{\Theta}(y)$ and $F_{\Theta}(y)$ denote the PDF and CDF respectively, evaluated at y for a set of parameter values Θ . Then, the set of input observations can be categorized into the following four subsets within each BY group:

- E : the set of uncensored observations that are not left-truncated. The likelihood of an observation $i \in E$ is

$$l_{i \in E} = \Pr(Y = y_i) = f_{\Theta}(y_i)$$

- E_l : the set of uncensored observations that are left-truncated. The likelihood of an observation $j \in E_l$ is

$$l_{j \in E_l} = \Pr(Y = y_j | Y > t_j) = \frac{f_{\Theta}(y_j)}{1 - F_{\Theta}(t_j)}$$

- C : the set of right-censored observations that are not left-truncated. The likelihood of an observation $k \in C$ is

$$l_{k \in C} = \Pr(Y > c_k) = 1 - F_{\Theta}(c_k)$$

- C_l : the set of right-censored observations that are left-truncated. The likelihood of an observation $m \in C_l$ is

$$l_{m \in C_l} = \Pr(Y > c_m | Y > t_m) = \frac{1 - F_{\Theta}(c_m)}{1 - F_{\Theta}(t_m)}$$

Note that $(E \cup E_l) \cap (C \cup C_l) = \emptyset$. Also, the sets E_l and C_l are empty when left-truncation is not specified, and the sets C and C_l are empty when right-censoring is not specified.

Given this, the likelihood of the data L is as follows:

$$L = \prod_{i \in E} f_{\Theta}(y_i) \prod_{j \in E_l} \frac{f_{\Theta}(y_j)}{1 - F_{\Theta}(t_j)} \prod_{k \in C} 1 - F_{\Theta}(c_k) \prod_{m \in C_l} \frac{1 - F_{\Theta}(c_m)}{1 - F_{\Theta}(t_m)}$$

The maximum likelihood procedure used by PROC SEVERITY finds an optimal set of parameter values $\hat{\Theta}$ that maximizes $\log(L)$ subject to the boundary constraints on parameter values. Note that for a distribution *dist*, such boundary constraints can be specified by using the *dist_LOWERBOUNDS* and *dist_UPPERBOUNDS* subroutines. Some aspects of the optimization process can be controlled by using the *NLOPTIONS* statement.

Probability of Observability and Likelihood

If probability of observability is specified for the left-truncation, then PROC SEVERITY uses a modified likelihood function for each truncated observation. If the probability of observability is $p \in (0.0, 1.0]$, then for each left-truncated observation with truncation threshold t , there exist $(1 - p)/p$ observations with a response variable value less than or equal to t . Each such observation has a probability of $\Pr(Y \leq t) = F_{\Theta}(t)$. Thus, following the notation of the section “Likelihood Function” on page 1541, the likelihood of the data is as follows:

$$L = \prod_{i \in E} f_{\Theta}(y_i) \prod_{j \in E_l} f_{\Theta}(y_j) F_{\Theta}(t_j)^{\frac{1-p}{p}} \prod_{k \in C} 1 - F_{\Theta}(c_k) \prod_{m \in C_l} (1 - F_{\Theta}(c_m)) F_{\Theta}(t_m)^{\frac{1-p}{p}}$$

Note that the likelihood of the observations that are not left-truncated (observations in sets E and C) is not affected.

Estimating Covariance and Standard Errors

PROC SEVERITY computes an estimate of the covariance matrix of the parameters by using the asymptotic theory of the maximum likelihood estimators (MLE). If N denotes the number of observations used for estimating a parameter vector θ , then the theory states that as $N \rightarrow \infty$, the distribution of $\hat{\theta}$, the estimate of θ , converges to a normal distribution with mean θ and covariance \hat{C} such that $\mathbf{I}(\theta) \cdot \hat{C} \rightarrow 1$, where $\mathbf{I}(\theta) = -E [\nabla^2 \log(L(\theta))]$ is the information matrix for the likelihood of the data, $L(\theta)$. The covariance estimate is obtained by using the inverse of the information matrix.

In particular, if $\mathbf{G} = \nabla^2 \log(L(\theta))$ denotes the Hessian matrix of the log likelihood, then the covariance estimate is computed as

$$\hat{C} = \frac{N}{d} \mathbf{G}^{-1}$$

where d is a denominator determined by the *VARDEF=* option. If *VARDEF=N*, then $d = N$, which yields the asymptotic covariance estimate. If *VARDEF=DF*, then $d = N - k$, where k is number of

parameters (the model's degrees of freedom). The VARDEF=DF option is the default, because it attempts to correct the potential bias introduced by the finite sample.

The standard error s_i of the parameter θ_i is computed as the square root of the i th diagonal element of the estimated covariance matrix; that is, $s_i = \sqrt{\hat{C}_{ii}}$.

Note that covariance and standard error estimates might not be available if the Hessian matrix is found to be singular at the end of the optimization process. This can especially happen if the optimization process stops without converging.

Estimating Regression Effects

The SEVERITY procedure enables you to estimate the effects of regressor (exogenous) variables while fitting a distribution model if the distribution has a scale parameter or a log-transformed scale parameter.

Let x_j ($j = 1, \dots, k$) denote the k regressor variables. Let β_j denote the regression parameter that corresponds to the regressor x_j . If regression effects are not specified, then the model for the response variable Y is of the form

$$Y \sim \mathcal{F}(\Theta)$$

where \mathcal{F} is the distribution of Y with parameters Θ . This model is typically referred to as the error model. The regression effects are modeled by extending the error model to the following form:

$$Y \sim \exp\left(\sum_{j=1}^k \beta_j x_j\right) \cdot \mathcal{F}(\Theta)$$

Under this model, the distribution of Y is valid and belongs to the same parametric family as \mathcal{F} if and only if \mathcal{F} has a scale parameter. Let θ denote the scale parameter and Ω denote the set of nonscale distribution parameters of \mathcal{F} . Then the model can be rewritten as

$$Y \sim \mathcal{F}(\theta, \Omega)$$

such that θ is affected by the regressors as

$$\theta = \theta_0 \cdot \exp\left(\sum_{j=1}^k \beta_j x_j\right)$$

where θ_0 is the *base* value of the scale parameter. Thus, the regression model consists of the following parameters: θ_0 , Ω , and β_j ($j = 1, \dots, k$).

Given this form of the model, distributions without a scale parameter cannot be considered when regression effects are to be modeled. If a distribution does not have a direct scale parameter, then PROC SEVERITY accepts it only if it has a log-transformed scale parameter — that is, if it has a parameter $p = \log(\theta)$. You must define the `SCALETRANSFORM` function to specify the log-transformation when you define the distribution model.

Parameter Initialization for Regression Models

Let a random variable Y be distributed as $\mathcal{F}(\theta, \Omega)$, where θ is the scale parameter. By definition of the scale parameter, a random variable $W = Y/\theta$ is distributed as $\mathcal{G}(\Omega)$ such that $\mathcal{G}(\Omega) = \mathcal{F}(1, \Omega)$. Given a random error term e that is generated from a distribution $\mathcal{G}(\Omega)$, a value y from the distribution of Y can be generated as

$$y = \theta \cdot e$$

Taking the logarithm of both sides and using the relationship of θ with the regressors yields:

$$\log(y) = \log(\theta_0) + \sum_{j=1}^k \beta_j x_j + \log(e)$$

If you do not provide initial values for the regression and distribution parameters, then PROC SEVERITY makes use of the preceding relationship to initialize parameters of a regression model with distribution *dist* as follows:

1. The following linear regression problem is solved to obtain initial estimates of β_0 and β_j :

$$\log(y) = \beta_0 + \sum_{j=1}^k \beta_j x_j$$

The estimates of β_j ($j = 1, \dots, k$) in the solution of this regression problem are used to initialize the respective regression parameters of the model.

The results of this regression are also used to detect whether any regressors are linearly dependent on the other regressors. If any such regressors are found, then a warning is written to the SAS log and the corresponding regressor is eliminated from further analysis. The estimates for linearly dependent regressors are denoted by a special missing value of .R in the OUTEST= data set and in any displayed output.

2. Each input value y_i of the response variable is transformed to its scale-normalized version w_i as

$$w_i = \frac{y_i}{\exp(\beta_0 + \sum_{j=1}^k \beta_j x_{ij})}$$

where x_{ij} denotes the value of j th regressor in the i th input observation. These w_i values are used to compute the input arguments for the *dist_PARMINIT* subroutine. The values that are computed by the subroutine for nonscale parameters are used as their respective initial values. Let s_0 denote the value of the scale parameter that is computed by the subroutine. If the distribution has a log-transformed scale parameter P , then s_0 is computed as $s_0 = \exp(l_0)$, where l_0 is the value of P computed by the subroutine.

3. The value of θ_0 is initialized as

$$\theta_0 = s_0 \cdot \exp(\beta_0)$$

If you provide initial values for the regression parameters, then you must provide valid, nonmissing initial values for θ_0 and β_j parameters.

You can use only the INEST= data set to specify the initial values for β_j . You can use the .R special missing value to denote redundant regressors if any such regressors are specified in the MODEL statement.

Initial values for θ_0 and other distribution parameters can be specified using either the INEST= data set or the INIT= option in the DIST statement. If the distribution has a direct scale parameter (no transformation), then the initial value for the first parameter of the distribution is used as an initial value for θ_0 . If the distribution has a log-transformed scale parameter, then the initial value for the first parameter of the distribution is used as an initial value for $\log(\theta_0)$.

Reporting Estimates of Regression Parameters

When you request estimates to be written to the output (either ODS displayed output or in the OUTEST= data set), the estimate of the base value of the first distribution parameter is reported. If the first parameter is the log-transformed scale parameter, then the estimate of $\log(\theta_0)$ is reported; otherwise, the estimate of θ_0 is reported. The transform of the first parameter of a distribution *dist* is controlled by the *dist_SCALETRANSFORM* function that is defined for it.

CDF and PDF Estimates with Regression Effects

When regression effects are estimated, the estimate of the scale parameter depends on the values of the regressors and estimates of the regression parameters. This results in a potentially different distribution for each observation. In order to make estimates of the cumulative distribution function (CDF) and probability density function (PDF) comparable across distributions and comparable to the empirical distribution function (EDF), PROC SEVERITY reports the CDF and PDF estimates from a mixture distribution. This mixture distribution is an equally weighted mixture of N distributions, where N is the number of observations used for estimation. Each component of the mixture differs only in the value of the scale parameter.

In particular, let $f(y; \hat{\theta}_i, \hat{\Omega})$ and $F(y; \hat{\theta}_i, \hat{\Omega})$ denote the PDF and CDF, respectively, of the component distribution due to observation i , where y denotes the value of the response variable, $\hat{\theta}_i$ denotes the estimate of the scale parameter due to observation i , and $\hat{\Omega}$ denotes the set of estimates of all other parameters of the distribution. The value of θ_i is computed as

$$\hat{\theta}_i = \hat{\theta}_0 \cdot \exp\left(\sum_{j=1}^k \hat{\beta}_j x_{ij}\right)$$

where $\hat{\theta}_0$ is an estimate of the base value of the scale parameter, $\hat{\beta}_j$ are the estimates of regression coefficients, and x_{ij} is the value of regressor j in observation i . Then, the PDF and CDF estimates, $f^*(y)$ and $F^*(y)$, respectively, of the mixture distribution at y are computed as follows:

$$f^*(y) = \frac{1}{N} \sum_{i=1}^N f(y; \hat{\theta}_i, \hat{\Omega})$$

$$F^*(y) = \frac{1}{N} \sum_{i=1}^N F(y; \hat{\theta}_i, \hat{\Omega})$$

The CDF estimates reported in OUTCDF= data set and plotted in CDF plots are the $F^*(y)$ values. The PDF estimates plotted in PDF plots are the $f^*(y)$ values.

If left-truncation is specified without the probability of observability, then the conditional CDF estimate from the mixture distribution is computed as follows: Let $F^*(y)$ denote an unconditional mixture estimate of the CDF at y and t_{\min} be the smallest value of the left-truncation threshold. Let $F^*(t_{\min})$ denote an unconditional mixture estimate of the CDF at t_{\min} . Then, the conditional mixture estimate of the CDF at y is computed as $F^{*c}(y) = (F^*(y) - F^*(t_{\min})) / (1 - F^*(t_{\min}))$.

Parameter Initialization

PROC SEVERITY enables you to initialize parameters of a model in different ways. There can be two kinds of parameters in a model: distribution parameters and regression parameters.

The distribution parameters can be initialized by using one of the following three methods:

PARMINIT subroutine	You can define a PARMINIT subroutine in the distribution model.
INEST= data set	You can use the INEST= data set.
INIT= option	You can use the INIT= option in the DIST statement.

Note that only one of the initialization methods is used. You cannot combine them. They are used in the following order:

- The method of using the INIT= option takes the highest precedence. If you use the INIT= option to provide an initial value for at least one parameter, then other initialization methods (INEST= and PARMINIT) are not used. If you specify initial values for some but not all the parameters by using the INIT= option, then the uninitialized parameters are initialized to the default value of 0.001.
If this option is used when regression effects are specified, then the value of the first distribution parameter must be related to the initial value for the *base* value of the scale or log-transformed scale parameter. See the section “[Estimating Regression Effects](#)” on page 1543 for details.
- The method of using the INEST= data set takes the second precedence. If there is a nonmissing value specified for even one distribution parameter, then the PARMINIT method is not used and any uninitialized parameters are initialized to the default value of 0.001.
- If none of the distribution parameters are initialized by using the INIT= option or the INEST= data set, but the distribution model defines a PARMINIT subroutine, then PROC SEVERITY invokes that subroutine with appropriate inputs to initialize the parameters. If the PARMINIT subroutine returns missing values for some parameters, then those parameters are initialized to the default value of 0.001.
- If none of the initialization methods are used, each distribution parameter is initialized to the default value of 0.001.

The regression parameters can be initialized by using the INEST= data set or the default method. If you use the INEST= data set, then you must specify nonmissing initial values for all the regressors. The only missing value allowed is the special missing value .R, which indicates that the regressor is linearly dependent on other regressors. If you specify .R for a regressor for one distribution in a BY group, you must specify it so for all the distributions in that BY group.

If you do not provide initial values for regressors by using the INEST= data set, then PROC SEVERITY computes them by fitting a linear regression model for $\log(y)$ on all the regressors with an intercept in the model, where y denotes the response variable. If it finds any linearly dependent regressors, warnings are printed to the SAS log and those regressors are dropped from the model. Details about estimating regression effects are provided in the section “[Estimating Regression Effects](#)” on page 1543.

Empirical Distribution Function Estimation Methods

The empirical distribution function (EDF) is a nonparametric estimate of the cumulative distribution function (CDF) of the distribution. PROC SEVERITY uses EDF estimates for computing the EDF-based statistics in addition to providing a nonparametric estimate of the CDF to the PARMINIT subroutine.

Let there be a set of N observations, each containing a triplet of values (y_i, t_i, δ_i) , $i = 1, \dots, N$, where y_i is the value of the response variable, t_i is the value of the left-truncation threshold, and δ_i is the indicator of right-censoring. A missing value for t_i indicates no left-truncation. $\delta_i = 0$ indicates a right-censored observation, in which case y_i is assumed to record the right-censoring limit c_i . $\delta_i \neq 0$ indicates an uncensored observation.

In the following definitions, an indicator function $I[e]$ is used, which takes a value of 1 or 0 if the expression e is true or false, respectively.

Given this notation, the EDF is estimated as follows:

$$F_n(y) = \begin{cases} 0 & \text{if } y < y^{(1)} \\ \hat{F}_n(y^{(k)}) & \text{if } y^{(k)} \leq y < y^{(k+1)}, k = 1, \dots, N-1 \\ \hat{F}_n(y^{(N)}) & \text{if } y^{(N)} \leq y \end{cases}$$

where $y^{(k)}$ denotes the k th order statistic of the set $\{y_i\}$ and $\hat{F}_n(y^{(k)})$ is the estimate computed at that value. The definition of \hat{F}_n depends on the estimation method. You can specify a particular method or let PROC SEVERITY choose an appropriate method by using the `EMPIRICALCDF=` option in the MODEL statement. Each method computes \hat{F}_n as follows:

STANDARD

This method is the standard way of computing EDF. The EDF estimate at observation i is computed as follows:

$$\hat{F}_n(y_i) = \frac{1}{N} \sum_{j=1}^N I[y_j \leq y_i]$$

This method ignores any censoring and truncation information, even if it is specified. When no censoring or truncation information is specified, this is the default method chosen.

KAPLANMEIER

This method is suitable primarily when left-truncation or right-censoring is specified. The Kaplan-Meier (KM) estimator, also known as the product-limit estimator, was first introduced by Kaplan and Meier (1958) for censored data. Lynden-Bell (1971) derived a similar estimator for left-truncated data. PROC SEVERITY uses the definition that combines both censoring and truncation information (Klein and Moeschberger 1997, Lai and Ying 1991).

The EDF estimate at observation i is computed as

$$\hat{F}_n(y_i) = 1 - \prod_{\tau \leq y_i} \left(1 - \frac{n_\tau}{R_n(\tau)}\right)$$

where n_τ and $R_n(\tau)$ are defined as follows:

- $n_\tau = \sum_{k=1}^N I[y_k = \tau \text{ and } \delta_k \neq 0]$, which is the number of uncensored observations with response variable value equal to τ .
- $R_n(\tau) = \sum_{k=1}^N I[y_k \geq \tau > t_k]$, which is the size (cardinality) of the risk set at τ . The term *risk set* has its origins in survival analysis; it contains the events that are at the risk of failure at a given time, τ . In other words, it contains the events that have survived up to time τ and might fail at or after τ . For PROC SEVERITY, *time* is equivalent to the magnitude of the event and *failure* is equivalent to an uncensored and observable event, where observable means it satisfies the left-truncation threshold.

If you specify either right-censoring or left-truncation and do not explicitly specify a method of computing EDF, then this is the default method used.

MODIFIEDKM

The product-limit estimator used by the KAPLANMEIER method does not work well if the risk set size becomes very small. This can happen for right-censored data towards the right tail, and for left-truncated data at the left tail and propagate to the entire range of data. This was demonstrated by Lai and Ying (1991). They proposed a modification to the estimator that ignores the effects due to small risk set sizes.

The EDF estimate at observation i is computed as

$$\hat{F}_n(y_i) = 1 - \prod_{\tau \leq y_i} \left(1 - \frac{n_\tau}{R_n(\tau)} \cdot I[R_n(\tau) \geq cN^\alpha]\right)$$

where the definitions of n_τ and $R_n(\tau)$ are identical to those used for the KAPLANMEIER method described previously.

You can specify the values of c and α by using the **C=** and **ALPHA=** options. If you do not specify a value for c , the default value used is $c = 1$. If you do not specify a value for α , the default value used is $\alpha = 0.5$.

As an alternative, you can also specify an absolute lower bound, say L , on the risk set size by using the **RSLB=** option, in which case $I[R_n(\tau) \geq cN^\alpha]$ is replaced by $I[R_n(\tau) \geq L]$ in the definition.

EDF Estimates and Left-Truncation

If left-truncation is specified *without* the probability of observability, the estimate $\hat{F}_n(y)$ computed by KAPLANMEIER and MODIFIEDKM methods is a conditional estimate. In other words, $\hat{F}_n(y) = \Pr(Y \leq y | Y > \tau_G)$, where G denotes the (unknown) distribution function of t_i and $\tau_G = \inf\{s : G(s) > 0\}$. In other words, τ_G is the smallest threshold with a nonzero cumulative probability. For computational purposes, PROC SEVERITY computes τ_G as $\tau_G = \min\{t_k : 1 \leq k \leq N\}$.

If left-truncation is specified *with* the probability of observability p , then PROC SEVERITY uses the additional information provided by p to compute an unconditional estimate of the EDF. In particular, for each left-truncated observation i with response variable value y_i and truncation threshold t_i , an observation j is added with *weight* $w_j = (1 - p)/p$ and $y_j = t_j$. Each added observation is assumed to be uncensored; that is, $\delta_j = 1$. Weight on each original observation i is assumed to be 1; that is, $w_i = 1$. Let N^a denote the number of observations in this *appended* set of observations. Then, the specified EDF method is used by assuming no left-truncation. For the KAPLANMEIER and MODIFIEDKM methods, definitions of n_τ and $R_n(\tau)$ are modified to account for the weights on the observations. n_τ is now defined as $n_\tau = \sum_{k=1}^{N^a} w_k I[y_k = \tau \text{ and } \delta_k \neq 0]$, and $R_n(\tau)$ is defined as $R_n(\tau) = \sum_{k=1}^{N^a} w_k I[y_k \geq \tau]$. From the definition of $R_n(\tau)$, note that each observation in the appended set is assumed to be observed; that is, the left-truncation information is not used, because it was used along with p to add the observations. The estimate that is obtained using this method is an unconditional estimate of the EDF.

Statistics of Fit

PROC SEVERITY computes and reports various statistics of fit to indicate how well the estimated model fits the data. The statistics belong to two categories: likelihood-based statistics and EDF-based statistics. Statistics Neg2LogLike, AIC, AICC, and BIC are likelihood-based statistics, and statistics KS, AD, and CvM are EDF-based statistics. The following subsections provide definitions of each.

Likelihood-Based Statistics

Let $y_i, i = 1, \dots, N$ denote the response variable values. Let L be the likelihood as defined in the section “Likelihood Function” on page 1541. Let p denote the number of model parameters estimated. Note that $p = p_d + (k - k_r)$, where p_d is the number of distribution parameters, k is the number of regressors, if any, specified in the MODEL statement, and k_r is the number of regressors found to be linearly dependent (redundant) on other regressors. Given this notation, the likelihood-based statistics are defined as follows:

Neg2LogLike The log likelihood is reported as

$$\text{Neg2LogLike} = -2 \log(L)$$

The multiplying factor -2 makes it easy to compare it to the other likelihood-based statistics. A model with a smaller value of Neg2LogLike is deemed better.

AIC The Akaike's information criterion (AIC) is defined as

$$\text{AIC} = -2 \log(L) + 2p$$

A model with a smaller value of AIC is deemed better.

AICC The corrected Akaike's information criterion (AICC) is defined as

$$\text{AICC} = -2 \log(L) + \frac{2Np}{N - p - 1}$$

A model with a smaller value of AICC is deemed better. It corrects the finite-sample bias that AIC has when N is small compared to p . AICC is related to AIC as

$$\text{AICC} = \text{AIC} + \frac{2p(p + 1)}{N - p - 1}$$

As N becomes large compared to p , AICC converges to AIC. AICC is usually recommended over AIC as a model selection criterion.

BIC The Schwarz Bayesian information criterion (BIC) is defined as

$$\text{BIC} = -2 \log(L) + p \log(N)$$

A model with a smaller value of BIC is deemed better.

EDF-Based Statistics

This class of statistics is based on the difference between the estimate of the cumulative distribution function (CDF) and the estimate of the empirical distribution function (EDF). Let $y_i, i = 1, \dots, N$ denote the sample of N values of the response variable. Let $r_i = \sum_{j=1}^N I[y_j \leq y_i]$ denote the number of observations with a value less than or equal to y_i , where I is an indicator function. Let $F_n(y_i)$ denote the EDF estimate that is computed by using the method specified in the [EMPIRICALCDF=](#) option. Let $Z_i = \hat{F}(y_i)$ denote the estimate of the CDF. Let $F_n(Z_i)$ denote the EDF estimate of Z_i values that are computed using the same method that is used to compute the EDF of y_i values. Using the probability integral transformation, if $F(y)$ is the true distribution of the random variable Y , then the random variable $Z = F(y)$ is uniformly distributed between 0 and 1 (D'Agostino and Stephens 1986, Ch. 4). Thus, comparing $F_n(y_i)$ with $\hat{F}(y_i)$ is equivalent to comparing $F_n(Z_i)$ with $\hat{F}(Z_i) = Z_i$ (uniform distribution).

Note the following two points regarding which CDF estimates are used for computing the test statistics:

- If regressor variables are specified, then the CDF estimates Z_i used for computing the EDF test statistics are from a mixture distribution. See the section "[CDF and PDF Estimates with Regression Effects](#)" on page 1545 for details.
- If left-truncation is specified without the probability of observability and the method for computing the EDF estimate is [KAPLANMEIER](#) or [MODIFIEDKM](#), then $F_n(z_i)$ is a conditional estimate of the EDF, as noted in the section "[EDF Estimates and Left-Truncation](#)" on

page 1549. However, Z_i is an unconditional estimate of the CDF. So, a conditional estimate of the CDF needs to be used for computing the EDF-based statistics. It is denoted by $\hat{F}^c(y_i)$ and defined as:

$$\hat{F}^c(y_i) = \frac{\hat{F}(y_i) - \hat{F}(t_{\min})}{1 - \hat{F}(t_{\min})}$$

where $t_{\min} = \min_i \{t_i\}$ is the smallest value of the left-truncation threshold.

Note that if regressors are specified, then both $\hat{F}(y_i)$ and $\hat{F}(t_{\min})$ are computed from a mixture distribution, as indicated previously.

In the following, it is assumed that Z_i denotes an appropriate estimate of the CDF if left-truncation or regression effects are specified.

Given this, the EDF-based statistics of fit are defined as follows:

KS The Kolmogorov-Smirnov (KS) statistic computes the largest vertical distance between the CDF and the EDF. It is formally defined as follows:

$$KS = \sup_y |F_n(y) - F(y)|$$

If the STANDARD method is used to compute the EDF, then the following formula is used:

$$D^+ = \max_j \left(\frac{r_j}{N} - Z_j \right)$$

$$D^- = \max_j \left(Z_j - \frac{r_{j-1}}{N} \right)$$

$$KS = \sqrt{N} \max(D^+, D^-) + \frac{0.19}{\sqrt{N}}$$

Note that r_0 is assumed to be 0.

If the method used to compute the EDF is any method other than the STANDARD method, then the following formula is used:

$$D^+ = \max_j (F_n(Z_j) - Z_j), \text{ if } F_n(Z_j) \geq Z_j$$

$$D^- = \max_j (Z_j - F_n(Z_j)), \text{ if } F_n(Z_j) < Z_j$$

$$KS = \sqrt{N} \max(D^+, D^-) + \frac{0.19}{\sqrt{N}}$$

AD The Anderson-Darling (AD) statistic is a quadratic EDF statistic that is proportional to the expected value of the weighted squared difference between the EDF and CDF. It is formally defined as follows:

$$AD = N \int_{-\infty}^{\infty} \frac{(F_n(y) - F(y))^2}{F(y)(1 - F(y))} dF(y)$$

If the STANDARD method is used to compute the EDF, then the following formula is used:

$$AD = -N - \frac{1}{N} \sum_{i=1}^N [(2r_i - 1) \log(Z_i) + (2N + 1 - 2r_i) \log(1 - Z_i)]$$

If the method used to compute the EDF is any method other than the STANDARD method, then the statistic can be computed by using the following two pieces of information:

- The EDF estimate is a step function. In the interval $[Z_{i-1}, Z_i]$, it is equal to $F_n(Z_{i-1})$.
- Using the probability integral transform $z = F(y)$, the formula simplifies to

$$AD = N \int_{-\infty}^{\infty} \frac{(F_n(z) - z)^2}{z(1-z)} dz$$

The computation formula can then be derived from the following approximation:

$$AD = N \sum_{i=1}^{N+1} \int_{Z_{i-1}}^{Z_i} \frac{(F_n(Z_{i-1}) - z)^2}{z(1-z)} dz$$

Assuming $Z_0 = 0$, $Z_{N+1} = 1$, $F_n(0) = 0$, and $F_n(Z_N) = 1$ yields the following computation formula:

$$AD = -N - N \log(1 - Z_1) - N \log(Z_N) \\ + N \sum_{i=2}^N [F_n(Z_{i-1})^2 B_i - (F_n(Z_{i-1}) - 1)^2 C_i]$$

where $B_i = \log(Z_i) - \log(Z_{i-1})$ and $C_i = \log(1 - Z_i) - \log(1 - Z_{i-1})$.

CvM

The Cramér-von-Mises (CvM) statistic is a quadratic EDF statistic that is proportional to the expected value of the squared difference between the EDF and CDF. It is formally defined as follows:

$$CvM = N \int_{-\infty}^{\infty} (F_n(y) - F(y))^2 dF(y)$$

If the STANDARD method is used to compute the EDF, then the following formula is used:

$$CvM = \frac{1}{12N} + \sum_{i=1}^N \left(Z_i - \frac{(2r_i - 1)}{2N} \right)^2$$

If the method used to compute the EDF is any method other than the STANDARD method, then the statistic can be computed by using the following two pieces of information:

- The EDF estimate is a step function. In the interval $[Z_{i-1}, Z_i]$, it is equal to $F_n(Z_{i-1})$.
- Using the probability integral transform $z = F(y)$, the formula simplifies to:

$$CvM = N \int_{-\infty}^{\infty} (F_n(z) - z)^2 dz$$

The computation formula can then be derived from the following approximation:

$$CvM = N \sum_{i=1}^{N+1} \int_{Z_{i-1}}^{Z_i} (F_n(Z_{i-1}) - z)^2 dz$$

Assuming $Z_0 = 0$, $Z_{n+1} = 1$, and $F_n(0) = 0$ yields the following computation formula:

$$\text{CvM} = \frac{N}{3} + N \sum_{i=2}^{N+1} [F_n(Z_{i-1})^2(Z_i - Z_{i-1}) - F_n(Z_{i-1})(Z_i^2 - Z_{i-1}^2)]$$

This formula is similar to the one proposed by Koziol and Green (1976).

Output Data Sets

PROC SEVERITY writes OUTEST=, OUTSTAT=, OUTCDF=, and OUTMODELINFO= data sets when requested with respective options. The data sets and their contents are described in the following sections.

OUTEST= Data Set

The OUTEST= data set records the estimates of the model parameters. It also contains estimates of their standard errors and optionally, their covariance structure. If BY variables are specified, then the data are organized in BY groups and the data set contains variables specified in the BY statement.

If the COVOUT option is not specified, then the data set contains the following variables:

<code>_MODEL_</code>	identifying name of the distribution model. The observation contains information about this distribution.
<code>_TYPE_</code>	type of the estimates reported in this observation. It can take one of the following two values:
EST	point estimates of model parameters
STDERR	standard error estimates of model parameters
<code>_STATUS_</code>	status of the reported estimates. The possible values are listed in the section “ _STATUS_ Variable Values ” on page 1556.

<Parameter 1> ... <Parameter M>

M variables, named after the parameters of all candidate distributions, containing estimates of the respective parameters. M is the cardinality of the union of parameter name sets from all candidate distributions. In an observation, estimates are populated only for parameters that correspond to the distribution specified by the `_MODEL_` variable. If `_TYPE_` is EST, then the estimates are missing if the model does not converge. If `_TYPE_` is STDERR, then the estimates are missing if covariance estimates cannot be obtained.

If regressors are specified, then the estimate reported for the first parameter of each distribution is the estimate of the base value of the scale or log-transformed scale parameter. See the section “[Estimating Regression Effects](#)” on page 1543 for details.

<Regressor 1> ... <Regressor K>

If K regressors are specified in the **MODEL** statement, then the OUTEST= data set contains K variables that are named for each regressor. The variables contain estimates for their respective regression coefficients. If a regressor is deemed to be linearly dependent on other regressors for a given BY group, then a warning message is printed to the SAS log and a special missing value of .R is written in the respective variable. If _TYPE_ is EST, then the estimates are missing if the model does not converge. If _TYPE_ is STDERR, then the estimates are missing if covariance estimates cannot be obtained.

If the COVOUT option is specified, then the OUTEST= data set contains additional observations that contain the estimates of the covariance structure. Given the symmetric nature of the covariance structure, only the lower triangular portion is reported. In addition to the variables listed and described previously, the data set contains the following variables that are either new or have a modified description:

TYPE	type of the estimates reported in this observation. For observations that contain rows of the covariance structure, the value is COV.
STATUS	status of the reported estimates. For observations that contain rows of the covariance structure, the status is 0 if covariance estimation was successful. If estimation fails, the status is 1 and a single observation is reported with _TYPE_=COV and missing values for all the parameter variables.
NAME	Name of the parameter for the row of covariance matrix reported in the current observation.

OUTSTAT= Data Set

The OUTSTAT= data set records statistics of fit and model selection information. If BY variables are specified, then the data are organized in BY groups and the data set contains variables specified in the BY statement. The data set contains the following variables:

MODEL	identifying name of the distribution model. The observation contains information about this distribution.
NMODELPARAM	number of parameters in the distribution.
NESTPARAM	number of estimated parameters. This includes the regression parameters, if any regressors are specified.
NOBS	number of nonmissing observations used for parameter estimation.
STATUS	status of the parameter estimation process for this model. The possible values are listed in the section “_STATUS_ Variable Values” on page 1556.
SELECTED	indicator of the best distribution model. If the value is 1, then this model is the best model for the current BY group according to the specified model selection criterion. This value is missing if parameter estimation process does not converge for this model.

Neg2LogLike	value of the log likelihood, multiplied by -2 , that is attained at the end of the parameter estimation process. This value is missing if parameter estimation process does not converge for this model.
AIC	value of the Akaike's information criterion (AIC) that is attained at the end of the parameter estimation process. This value is missing if parameter estimation process does not converge for this model.
AICC	value of the corrected Akaike's information criterion (AICC) that is attained at the end of the parameter estimation process. This value is missing if parameter estimation process does not converge for this model.
BIC	value of the Schwarz Bayesian information criterion (BIC) that is attained at the end of the parameter estimation process. This value is missing if parameter estimation process does not converge for this model.
KS	value of the Kolmogorov-Smirnov (KS) statistic that is attained at the end of the parameter estimation process. This value is missing if parameter estimation process does not converge for this model.
AD	value of the Anderson-Darling (AD) statistic that is attained at the end of the parameter estimation process. This value is missing if parameter estimation process does not converge for this model.
CVM	value of the Cramér-von-Mises (CvM) statistic that is attained at the end of the parameter estimation process. This value is missing if parameter estimation process does not converge for this model.

OUTCDF= Data Set

The OUTCDF= data set records the estimates of the cumulative distribution function (CDF) of each of the specified model distributions and an estimate of the empirical distribution function (EDF).

If BY variables are specified, then the data are organized in BY groups and the data set contains variables specified in the BY statement. In addition, it contains the following variables:

<response variable>

value of the response variable. The values are sorted. If there are multiple BY groups, the values are sorted within each BY group.

OBSNUM observation number in the DATA= data set.

EDF estimate of the empirical distribution function (EDF). This estimate is computed by using the [EMPIRICALCDF=](#) option specified in the MODEL statement.

<distribution1>_CDF ... <distributionD>_CDF

estimate of the cumulative distribution function (CDF) for each of the D candidate distributions, computed by using the final parameter estimates for that distribution. This value is missing if parameter estimation process does not converge for the given distribution.

If regressor variables are specified, then the reported estimates are from a mixture distribution. See the section "[CDF and PDF Estimates with Regression Effects](#)" on page 1545 for details.

If left-truncation is specified and the probability of observability is not specified, then the data set contains the following additional variables:

<distribution1>_COND_CDF ... <distributionD>_COND_CDF

estimate of the conditional CDF for each of the D candidate distributions, computed by using the final parameter estimates for that distribution. This value is missing if parameter estimation process does not converge for the distribution. If $\hat{F}(y)$ denotes an unconditional CDF at y and t_{\min} is the smallest left-truncation threshold value, then the conditional CDF is $\hat{F}^c(y) = (\hat{F}(y) - \hat{F}(t_{\min})) / (1 - \hat{F}(t_{\min}))$.

OUTMODELINFO= Data Set

The OUTMODELINFO= data set records the information about each specified distribution. If BY variables are specified, then the data are organized in BY groups and the data set contains variables specified in the BY statement. In addition, it contains the following variables:

<code>_MODEL_</code>	identifying name of the distribution model. The observation contains information about this distribution.
<code>_DESCRIPTION_</code>	descriptive name of the model. This has a nonmissing value only if the DESCRIPTION function has been defined for this model.
<code>_PARAMNAME1 ... _PARAMNAMEM</code>	M variables that contain names of parameters of the distribution model, where M is the maximum number of parameters across all the specified distribution models. For a given distribution with m parameters, values of variables <code>_PARAMNAMEj</code> ($j > m$) are missing.

`_STATUS_` Variable Values

The `_STATUS_` variable in the OUTEST= and OUTSTAT= data sets contains a value that indicates the status of the parameter estimation process for the respective distribution model. The variable can take the following values in the OUTEST= data set for `_TYPE_=EST` observations and in the OUTSTAT= data set:

- 0 The parameter estimation process converged for this model.
- 301 The parameter estimation process might not have converged for this model because there is no improvement in the objective function value. This might indicate that the initial values of the parameters are optimal, or you can try different convergence criteria in the `NLOPTIONS` statement.
- 302 The parameter estimation process might not have converged for this model because the number of iterations exceeded the maximum allowed value. You can try setting a larger value for the `MAXITER=` options in the `NLOPTIONS` statement.
- 303 The parameter estimation process might not have converged for this model because the number of objective function evaluations exceeded the maximum allowed value. You can try setting a larger value for the `MAXFUNC=` options in the `NLOPTIONS` statement.

- 304 The parameter estimation process might not have converged for this model because the time taken by the process exceeded the maximum allowed value. You can try setting a larger value for the MAXTIME= option in the NLOPTIONS statement.
- 400 The parameter estimation process did not converge for this model.

The _STATUS_ variable can take the following values in the OUTEST= data set for _TYPE_=STDERR and _TYPE_=COV observations:

- 0 The covariance and standard error estimates are available and valid.
- 1 The covariance and standard error estimates are not available, because the process of computing covariance estimates failed.

Input Data Sets

PROC SEVERITY accepts DATA= and INEST= data sets as input data sets. This section details the information they are expected to contain.

DATA= Data Set

The DATA= data set is expected to contain the values of the analysis variables specified in the MODEL statement.

If BY variables are specified in the BY statement, then the DATA= data set must contain all the variables specified in the BY statement and the data set must be sorted by the BY variables unless the NOTSORTED option is used in the BY statement.

The data set must also contain the following variables:

<response variable>

the response variable that is specified in the MODEL statement.

<Regressor 1> ... <Regressor K>

K regressor variables that are specified in the MODEL statement. K can be 0.

<left-truncation variable>

If a left-truncation variable is specified by using the LEFTTRUNCATED= option in the MODEL statement, then that variable must be present.

<right-censoring variable>

If a right-censoring indicator variable is specified by using the RIGHTCENSORED= option in the MODEL statement, then that variable must be present.

INEST= Data Set

The INEST= data set is expected to contain the initial values of the parameters for the parameter estimation process.

If BY variables are specified in the BY statement, then the INEST= data set must contain all the variables specified in the BY statement. If the NOTSORTED option is not specified in the BY statement, then the INEST= data set must be sorted by the BY variables. However, it is not required to contain all the BY groups present in the DATA= data set. For the BY groups that are not present in the INEST= data set, the default parameter initialization method is used. If the NOTSORTED option is specified in the BY statement, then the INEST= data set must contain all the BY groups that are present in the DATA= data set and they must appear in the same order as they appear in the DATA= data set.

In addition to any variables specified in the BY statement, the data set must contain the following variables:

`_MODEL_` identifying name of the distribution for which the estimates are provided.
`_TYPE_` type of the estimate. The value of this variable must be EST for an observation to be valid.

<Parameter 1> ... <Parameter M>

M variables, named after the parameters of all candidate distributions, that contain initial values of the respective parameters. M is the cardinality of the union of parameter name sets from all candidate distributions. In an observation, estimates are read only from variables for parameters that correspond to the distribution specified by the `_MODEL_` variable.

If you specify a missing value for some parameters, then default initial values are used unless the parameter is initialized by using the `INIT=` option in the DIST statement. If you want to use the `dist_PARMINIT` subroutine for initializing the parameters of a model, then you should either not specify the model in the INEST= data set or specify missing values for all the distribution parameters in the INEST= data set and not use the `INIT=` option in the DIST statement.

If regressors are specified, then the initial value provided for the first parameter of each distribution must be the base value of the scale or log-transformed scale parameter. See the section “[Estimating Regression Effects](#)” on page 1543 for details.

<Regressor 1> ... <Regressor K>

If K regressors are specified in the `MODEL` statement, then the INEST= data set must contain K variables that are named for each regressor. The variables contain initial values of the respective regression coefficients. If a regressor is linearly dependent on other regressors for a given BY group, then you can indicate this by providing a special missing value of `.R` for the respective variable. In a given BY group, if a variable is marked as linearly dependent for one model, then it must be marked so for all the models. Similarly, if a variable is not marked as linearly dependent for one model, then it must be marked so for all the models.

Displayed Output

The SEVERITY procedure optionally produces displayed output by using the Output Delivery System (ODS). By default, the procedure produces no displayed output. All output is controlled by the PRINT= option in the PROC SEVERITY statement. Table 22.5 relates the PRINT= options to ODS tables.

Table 22.5 ODS Tables Produced in PROC SEVERITY

ODS Table Name	Description	Option
DescStats	Descriptive statistics for the response variable	PRINT=DESCSTATS
RegDescStats	Descriptive statistics for the regressor variables	PRINT=DESCSTATS
ModelSelection	Model selection summary	PRINT=SELECTION
AllFitStatistics	Statistics of fit for all the distribution models	PRINT=ALLFITSTATS
InitialValues	Initial parameter values and bounds	PRINT=INITIALVALUES
ConvergenceStatus	Convergence status of parameter estimation process	PRINT=CONVSTATUS
IterationHistory	Optimization iteration history	PRINT=NLOHISTORY
OptimizationSummary	Optimization summary	PRINT=NLOSUMMARY
StatisticsOfFit	Statistics of fit	PRINT=STATISTICS
ParameterEstimates	Final parameter estimates	PRINT=ESTIMATES

PRINT=DESCSTATS

displays the descriptive statistics for the response variable. If regressor variables are specified, a table with their descriptive statistics is also displayed.

PRINT=SELECTION

displays the model selection table. The table shows the convergence status of each candidate model, and the value of the selection criterion along with an indication of the selected model.

PRINT=ALLFITSTATS

displays the comparison of all the statistics of fit for all the models in one table. The table does not include the models whose parameter estimation process does not converge. If all the models fail to converge, then this table is not produced. If the table contains more than one model, then the best model according to each statistic is indicated with an asterisk (*) in that statistic's column.

PRINT=INITIALVALUES

displays the initial values and bounds used for estimating each model.

PRINT=CONVSTATUS

displays the convergence status of the parameter estimation process.

PRINT=NLOHISTORY

displays the iteration history of the nonlinear optimization process used for estimating the parameters.

PRINT=NLOSUMMARY

displays the summary of the nonlinear optimization process used for estimating the parameters.

PRINT=STATISTICS

displays the statistics of fit for each model. The statistics of fit are not displayed for models whose parameter estimation process does not converge.

PRINT=ESTIMATES

displays the final estimates of parameters. The estimates are not displayed for models whose parameter estimation process does not converge.

ODS Graphics

This section describes the use of ODS for creating graphics with the SEVERITY procedure.

To request these graphs, you must specify the ODS GRAPHICS statement. In addition, you can specify the PLOTS= option in the PROC SEVERITY statement as described in [Table 22.6](#).

ODS Graph Names

PROC SEVERITY assigns a name to each graph it creates by using ODS. You can use these names to selectively reference the graphs. The names are listed in [Table 22.6](#).

Table 22.6 ODS Graphics Produced by PROC SEVERITY

ODS Graph Name	Plot Description	PLOTS= Option
CDFPlot	Comparative CDF Plot	CDF
CDFDistPlot	CDF Plot per Distribution	CDFPERDIST
PDFPlot	Comparative PDF Plot	PDF
PDFDistPlot	PDF Plot per Distribution	PDFPERDIST
PPPlot	P-P Plot of CDF and EDF	PP

Comparative CDF Plot

The comparative CDF plot helps you visually compare the cumulative distribution function (CDF) estimates of all the candidate distribution models and the empirical distribution function (EDF) estimate. The plot does not contain CDF estimates for models whose parameter estimation process does not converge. The horizontal axis represents the values of the response variable. The vertical axis represents the values of the CDF or EDF estimates.

If left-truncation is specified and the probability of observability is not specified, then conditional CDF estimates are plotted. Otherwise, unconditional CDF estimates are plotted. If $\hat{F}(y)$ denotes an unconditional estimate of the CDF at y and t_{\min} is the smallest value of the left-truncation threshold, then the conditional CDF at y is $\hat{F}^c(y) = (\hat{F}(y) - \hat{F}(t_{\min})) / (1 - \hat{F}(t_{\min}))$.

If left-truncation is specified and the MARKTRUNCATED option is specified, then the left-truncated observations are marked in the plot. If right-censoring is specified and the MARKCENSORED option is specified, then the right-censored observations are marked in the plot.

If regressor variables are specified, then the plotted CDF estimates are from a mixture distribution. See the section “[CDF and PDF Estimates with Regression Effects](#)” on page 1545 for details.

CDF Plot per Distribution

The CDF plot per distribution shows the CDF estimates of each candidate distribution model unless that model’s parameter estimation process does not converge. The plot also contains estimates of the EDF. The horizontal axis represents the values of the response variable. The vertical axis represents the values of the CDF or EDF estimates.

If left-truncation is specified and the probability of observability is not specified, then conditional CDF estimates are plotted. Otherwise unconditional CDF estimates are plotted. If $\hat{F}(y)$ denotes an unconditional estimate of the CDF at y and t_{\min} is the smallest value of the left-truncation threshold, then the conditional CDF at y is $\hat{F}^c(y) = (\hat{F}(y) - \hat{F}(t_{\min})) / (1 - \hat{F}(t_{\min}))$.

If left-truncation is specified and the MARKTRUNCATED option is specified, then the left-truncated observations are marked in the plot. If right-censoring is specified and the MARKCENSORED option is specified, then the right-censored observations are marked in the plot.

If regressor variables are specified, then the plotted CDF estimates are from a mixture distribution. See the section “CDF and PDF Estimates with Regression Effects” on page 1545 for details.

Comparative PDF Plot

The comparative PDF plot helps you visually compare the probability density function (PDF) estimates of all the candidate distribution models. The plot does not contain PDF estimates for models whose parameter estimation process does not converge. The horizontal axis represents the values of the response variable. The vertical axis represents the values of the PDF estimates.

If the HISTOGRAM option is specified, then the plot also contains the histogram of response variable values. If the KERNEL option is specified, then the plot also contains the kernel density estimate for the response variable values.

If regressor variables are specified, then the plotted PDF estimates are from a mixture distribution. See the section “CDF and PDF Estimates with Regression Effects” on page 1545 for details.

PDF Plot per Distribution

The PDF plot per distribution shows the PDF estimates of each candidate distribution model unless that model’s parameter estimation process does not converge. The horizontal axis represents the values of the response variable. The vertical axis represents the values of the PDF estimates.

If the HISTOGRAM option is specified, then the plot also contains the histogram of response variable values. If the KERNEL option is specified, then the plot also contains the kernel density estimate for the response variable values.

If regressor variables are specified, then the plotted PDF estimates are from a mixture distribution. See the section “CDF and PDF Estimates with Regression Effects” on page 1545 for details.

P-P Plot of CDF and EDF

The P-P plot of CDF and EDF is the probability-probability plot that compares the CDF estimates of a distribution with the EDF estimates. A plot is not prepared for models whose parameter estimation process does not converge. The horizontal axis represents the CDF estimates of a candidate distribution and the vertical axis represents the EDF estimates.

This plot can be interpreted as displaying the data that is used for computing the EDF-based statistics of fit for the given candidate distribution. As described in the section “EDF-Based Statistics” on page 1550, these statistics are computed by comparing the EDF, denoted by $F_n(y)$, and the CDF, denoted by $F(y)$, at each of the response variable values y . Using the probability inverse transform $z = F(y)$, this is equivalent to comparing the EDF of the z , denoted by $F_n(z)$, and the CDF of z , denoted by $F(z)$ (D’Agostino and Stephens 1986, Ch. 4). Given that the CDF of z is a uniform

distribution ($F(z) = z$), the EDF-based statistics can be computed by comparing the EDF estimate of z with the estimate of z . The horizontal axis of the plot represents the estimated CDF $\hat{z} = \hat{F}(y)$. The vertical axis represents the estimated EDF of z , $\hat{F}_n(z)$. The plot contains a scatter plot of $(\hat{z}, \hat{F}_n(z))$ points and a reference line $F_n(z) = z$ that represents the expected uniform distribution of z . Points scattered closer to the reference line indicate a better fit than the points scattered away from the reference line.

If left-truncation is specified and the probability of observability is not specified, then the EDF estimates are conditional as described in the section “EDF Estimates and Left-Truncation” on page 1549. The displayed CDF estimates are also conditional estimates. If $\hat{F}(y)$ denotes an unconditional estimate of the CDF at y and t_{\min} is the smallest value of the left-truncation threshold, then the conditional estimate of the CDF at y is $\hat{F}^c(y) = (\hat{F}(y) - \hat{F}(t_{\min})) / (1 - \hat{F}(t_{\min}))$.

If regressor variables are specified, then the displayed CDF estimates, both unconditional and conditional, are from a mixture distribution. See the section “CDF and PDF Estimates with Regression Effects” on page 1545 for details.

Examples: SEVERITY Procedure

Example 22.1: Defining a Model for Gaussian Distribution

Suppose you want to fit a distribution model other than one of the predefined ones available to you. Suppose you want to define a model for the Gaussian distribution with the following typical parameterization of the PDF (f) and CDF (F):

$$f(x; \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x - \mu)^2}{2\sigma^2}\right)$$

$$F(x; \mu, \sigma) = \frac{1}{2} \left(1 + \operatorname{erf}\left(\frac{x - \mu}{\sigma\sqrt{2}}\right)\right)$$

For PROC SEVERITY, a *distribution model* consists of a set of functions and subroutines that are defined with the FCMP procedure. Each function and subroutine should be written following certain rules. The details are provided in the section “Defining a Distribution Model with the FCMP Procedure” on page 1519.

The following SAS statements define a distribution model named NORMAL for the Gaussian distribution. The OUTLIB= option in the PROC FCMP statement stores the compiled versions of the functions and subroutines in the ‘models’ package of the WORK.SEVEXMPL library. The LIBRARY= option in the PROC FCMP statement enables this PROC FCMP step to use the SVRTUTIL_RAWMOMENTS utility subroutine that is available in the SASHELP.SVRTDIST library. The subroutine is described in the section “Predefined Utility Functions” on page 1537.

```

/*----- Define Normal Distribution with PROC FCMP -----*/
proc fcmp library=sashelp.svrtldist outlib=work.sevexmpl.models;
  function normal_pdf(x,Mu,Sigma);
    /* Mu      : Location */
    /* Sigma   : Standard Deviation */
    return ( exp(-(x-Mu)**2/(2 * Sigma**2)) /
             (Sigma * sqrt(2*constant('PI')))) );
  endsub;

  function normal_cdf(x,Mu,Sigma);
    /* Mu      : Location */
    /* Sigma   : Standard Deviation */
    z = (x-Mu)/Sigma;
    return (0.5 + 0.5*erf(z/sqrt(2)));
  endsub;

  subroutine normal_parminit(dim, x[*], nx[*], F[*], Mu, Sigma);
    outargs Mu, Sigma;
    array m[2] / nosymbols;

    /* Compute estimates by using method of moments */
    call svrtutil_rawmoments(dim, x, nx, 2, m);
    Mu      = m[1];
    Sigma   = sqrt(m[2] - m[1]**2);
  endsub;

  subroutine normal_lowerbounds(Mu, Sigma);
    outargs Mu, Sigma;
    Mu = .; /* Mu has no lower bound */
    Sigma = 0; /* Sigma > 0 */
  endsub;
quit;

```

The statements define the two functions required of any distribution model (NORMAL_PDF and NORMAL_CDF) and two optional subroutines (NORMAL_PARMINIT and NORMAL_LOWERBOUNDS). The name of each function or subroutine must follow a specific structure. It should start with the model's short or identifying name, which is 'NORMAL' in this case, followed by an underscore '_', followed by a keyword suffix such as 'PDF'. Each function or subroutine has a specific purpose. The details of all the functions and subroutines that you can define for a distribution model are provided in the section [“Defining a Distribution Model with the FCMP Procedure”](#) on page 1519. Following is the description of each function and subroutine defined in this example:

- The PDF and CDF suffixes define functions that return the probability density function and cumulative distribution function values, respectively, given the values of the random variable and the distribution parameters.
- The PARMINIT suffix defines a subroutine that returns the initial values for the parameters by using the sample data or the empirical distribution function (EDF) estimate computed from it. In this example, the parameters are initialized by using the method of moments. Hence, you do not need to use the EDF estimates, which are available in the F array. The first two raw

moments of the Gaussian distribution are as follows:

$$E[x] = \mu, \quad E[x^2] = \mu^2 + \sigma^2$$

Given the sample estimates, m_1 and m_2 , of these two raw moments, you can solve the equations $E[x] = m_1$ and $E[x^2] = m_2$ to get the following estimates for the parameters: $\hat{\mu} = m_1$ and $\hat{\sigma} = \sqrt{m_2 - m_1^2}$. The NORMAL_PARMINIT subroutine implements this solution. It uses the SVRTUTIL_RAWMOMENTS utility subroutine to compute the first two raw moments.

- The LOWERBOUNDS suffix defines a subroutine that returns the lower bounds on the parameters. PROC SEVERITY assumes a default lower bound of 0 for all the parameters when a LOWERBOUNDS subroutine is not defined. For the parameter μ (*Mu*), there is no lower bound, so you need to define the NORMAL_LOWERBOUNDS subroutine. It is recommended that you assign bounds for all the parameters when you define the LOWERBOUNDS subroutine or its counterpart, the UPPERBOUNDS subroutine. Any unassigned value is returned as a missing value, which is interpreted by PROC SEVERITY to mean that the parameter is unbounded, and that might not be what you want.

You can now use this distribution model with PROC SEVERITY. Let the following DATA step statements simulate a normal sample with $\mu = 10$ and $\sigma = 2.5$.

```
/*----- Simulate a Normal sample -----*/
data testnorm(keep=y);
  call streaminit(12345);
  do i=1 to 100;
    y = rand('NORMAL', 10, 2.5);
    output;
  end;
run;
```

Prior to using your distribution with PROC SEVERITY, you must communicate the location of the library that contains the definition of the distribution and the locations of libraries that contain any functions and subroutines used by your distribution model. The following OPTIONS statement sets the CMLIB= system option to include the FCMP library WORK.SEVEXMPL in the search path used by PROC SEVERITY to find FCMP functions and subroutines.

```
/*--- Set the search path for functions defined with PROC FCMP ---*/
options cmlib=(work.sevexmpl);
```

Now, you are ready to fit the NORMAL distribution model with PROC SEVERITY. The following statements fit the model to the values of Y in the WORK.TESTNORM data set:

```
/*--- Fit models with PROC SEVERITY ---*/
proc severity data=testnorm print=all;
  model y;
  dist Normal;
run;
```

The DIST statement specifies the identifying name of the distribution model, which is 'NORMAL'. Neither is the INEST= option specified in the PROC SEVERITY statement nor is the INIT= option specified in the DIST statement. So, PROC SEVERITY initializes the parameters by invoking the NORMAL_PARMINIT subroutine.

Some of the results prepared by the preceding PROC SEVERITY step are shown in [Output 22.1.1](#) and [Output 22.1.2](#). The descriptive statistics of variable Y and the model selection table, which includes just the normal distribution, are shown in [Output 22.1.1](#).

Output 22.1.1 Summary of Results for Fitting the Normal Distribution

The SEVERITY Procedure			
Input Data Set			
Name	WORK.TESTNORM		
Descriptive Statistics for Variable y			
Number of Observations			100
Number of Observations Used for Estimation			100
Minimum			3.88249
Maximum			16.00864
Mean			10.02059
Standard Deviation			2.37730
Model Selection Table			
Distribution	Converged	-2 Log Likelihood	Selected
Normal	Yes	455.97541	Yes

The initial values for the parameters, the optimization summary, and the final parameter estimates are shown in [Output 22.1.2](#). No iterations are required to arrive at the final parameter estimates, which are identical to the initial values. This confirms the fact that the maximum likelihood estimates for the Gaussian distribution are identical to the estimates obtained by the method of moments that was used to initialize the parameters in the NORMAL_PARMINIT subroutine.

Output 22.1.2 Details of the Fitted Normal Distribution Model

Output 22.1.2 *continued*

Optimization Summary for Normal Distribution				
Optimization Technique		Trust Region		
Number of Iterations				0
Number of Function Evaluations				2
Log Likelihood				-227.98770
Parameter Estimates for Normal Distribution				
Parameter	Estimate	Standard Error	t Value	Approx Pr > t
Mu	10.02059	0.23894	41.94	<.0001
Sigma	2.36538	0.16896	14.00	<.0001

The NORMAL distribution defined and illustrated here has no scale parameter, because all the following inequalities are true:

$$f(x; \mu, \sigma) \neq \frac{1}{\mu} f\left(\frac{x}{\mu}; 1, \sigma\right)$$

$$f(x; \mu, \sigma) \neq \frac{1}{\sigma} f\left(\frac{x}{\sigma}; \mu, 1\right)$$

$$F(x; \mu, \sigma) \neq F\left(\frac{x}{\mu}; 1, \sigma\right)$$

$$F(x; \mu, \sigma) \neq F\left(\frac{x}{\sigma}; \mu, 1\right)$$

This implies that you cannot estimate the effect of regressors on a model for the response variable based on this distribution.

Example 22.2: Defining a Model for Gaussian Distribution with a Scale Parameter

If you want to estimate the effects of regressors, then the model needs to be parameterized to have a scale parameter. While this might not be always possible, for the case of the Gaussian distribution it is possible by replacing the location parameter μ with another parameter, $\alpha = \mu/\sigma$, and defining the PDF (f) and the CDF (F) as follows:

$$f(x; \sigma, \alpha) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{1}{2}\left(\frac{x}{\sigma} - \alpha\right)^2\right)$$

$$F(x; \sigma, \alpha) = \frac{1}{2} \left(1 + \operatorname{erf}\left(\frac{1}{\sqrt{2}}\left(\frac{x}{\sigma} - \alpha\right)\right)\right)$$

It can be verified that σ is the scale parameter, because both of the following equalities are true:

$$f(x; \sigma, \alpha) = \frac{1}{\sigma} f\left(\frac{x}{\sigma}; 1, \alpha\right)$$

$$F(x; \sigma, \alpha) = F\left(\frac{x}{\sigma}; 1, \alpha\right)$$

The following statements use this parameterization to define a new model named NORMAL_S. The definition is stored in the WORK.SEVEXMPL library.

```

/*----- Define Normal Distribution With Scale Parameter -----*/
proc fcmp library=sashelp.svrtldist outlib=work.sevexmpl.models;
  function normal_s_pdf(x, Sigma, Alpha);
    /* Sigma : Scale & Standard Deviation */
    /* Alpha : Scaled mean */
    return ( exp(-(x/Sigma - Alpha)**2/2) /
             (Sigma * sqrt(2*constant('PI'))) );
  endsub;

  function normal_s_cdf(x, Sigma, Alpha);
    /* Sigma : Scale & Standard Deviation */
    /* Alpha : Scaled mean */
    z = x/Sigma - Alpha;
    return (0.5 + 0.5*erf(z/sqrt(2)));
  endsub;

  subroutine normal_s_parminit(dim, x[*], nx[*], F[*], Sigma, Alpha);
    outargs Sigma, Alpha;
    array m[2] / nosymbols;

    /* Compute estimates by using method of moments */
    call svrtutil_rawmoments(dim, x, nx, 2, m);
    Sigma = sqrt(m[2] - m[1]**2);
    Alpha = m[1]/Sigma;
  endsub;

  subroutine normal_s_lowerbounds(Sigma, Alpha);
    outargs Sigma, Alpha;
    Alpha = .; /* Alpha has no lower bound */
    Sigma = 0; /* Sigma > 0 */
  endsub;
quit;

```

An important point to note is that the scale parameter *Sigma* is the first distribution parameter (after the 'x' argument) listed in the signatures of NORMAL_S_PDF and NORMAL_S_CDF functions. *Sigma* is also the first distribution parameter listed in the signatures of other subroutines. This is required by PROC SEVERITY, so that it can identify which is the scale parameter. When regressor variables are specified, PROC SEVERITY checks whether the first parameter of each candidate distribution is a scale parameter (or a log-transformed scale parameter if SCALETRANSFORM subroutine is defined for the distribution with LOG as the transform). If it is not, then an appropriate message is written the SAS log and that distribution is not fitted.

Let the following DATA step statements simulate a sample from the normal distribution where the parameter σ is affected by the regressors as follows:

$$\sigma = \exp(1 + 0.5 X1 + 0.75 X3 - 2 X4 + X5)$$

The sample is simulated such that the regressor X2 is linearly dependent on regressors X1 and X3.

```

/*--- Simulate a Normal sample affected by Regressors ---*/
data testnorm_reg(keep=y x1-x5 Sigma);
  array x{*} x1-x5;
  array b{6} _TEMPORARY_ (1 0.5 . 0.75 -2 1);
  call streaminit(34567);
  label y='Normal Response Influenced by Regressors';

  do n = 1 to 100;
    /* simulate regressors */
    do i = 1 to dim(x);
      x(i) = rand('UNIFORM');
    end;
    /* make x2 linearly dependent on x1 and x3 */
    x(2) = x(1) + 5 * x(3);

    /* compute log of the scale parameter */
    logSigma = b(1);
    do i = 1 to dim(x);
      if (i ne 2) then
        logSigma = logSigma + b(i+1) * x(i);
    end;

    Sigma = exp(logSigma);
    y = rand('NORMAL', 25, Sigma);

    output;
  end;
run;

```

The following statements use PROC SEVERITY to fit the NORMAL_S distribution model along with some of the predefined distributions to the simulated sample:

```

/*--- Set the search path for functions defined with PROC FCMP ---*/
options cmplib=(work.sevexmpl);

/*----- Fit models with PROC SEVERITY -----*/
proc severity data=testnorm_reg print=all plots=none;
  model y=x1-x5;
  dist Normal_s;
  dist burr;
  dist logn;
  dist pareto;
  dist weibull;
run;

```

The model selection table prepared by PROC SEVERITY is shown in [Output 22.2.1](#). It indicates that all the models, except the Burr distribution model, have converged. Also, only three models, Normal_s, Burr, and Weibull, seem to have a good fit for the data. The table that compares all the fit statistics indicates that Normal_s model is the best according to the likelihood-based statistics; however, the Burr model is the best according to the EDF-based statistics.

Output 22.2.1 Summary of Results for Fitting the Normal Distribution with Regressors

The SEVERITY Procedure					
Input Data Set					
Name	WORK.TESTNORM_REG				
Model Selection Table					
Distribution	Converged	-2 Log Likelihood		Selected	
Normal_s	Yes	603.95786		Yes	
Burr	Maybe	612.80861		No	
Logn	Yes	749.20125		No	
Pareto	Yes	841.07013		No	
Weibull	Yes	612.77496		No	
All Fit Statistics Table					
Distribution	-2 Log Likelihood	AIC	AICC	BIC	KS
Normal_s	603.95786*	615.95786*	616.86108*	631.58888*	1.56822*
Burr	612.80861	626.80861	628.02600	645.04480	1.59005
Logn	749.20125	761.20125	762.10448	776.83227	2.89985
Pareto	841.07013	853.07013	853.97336	868.70115	4.83826
Weibull	612.77496	624.77496	625.67819	640.40598	1.59176
All Fit Statistics Table					
Distribution	AD	CvM			
Normal_s	4.25257	0.75658			
Burr	4.21979*	0.71880*			
Logn	16.57630	3.13174			
Pareto	31.60773	6.84091			
Weibull	4.22441	0.71985			

This prompts for further evaluation of why the model with Burr distribution has not converged. The initial values, convergence status, and the optimization summary for the Burr distribution are shown in [Output 22.2.2](#). The initial values table indicates that the regressor X2 is redundant, which is expected. More importantly, the convergence status indicates that it requires more than 50 iterations. PROC SEVERITY enables you to change several settings of the optimizer by using the **NLOPTIONS** statement. In this case, you can increase the limit of 50 on the iterations, change the convergence criterion, or change the technique to something other than the default trust-region technique.

Output 22.2.2 Details of the Fitted Burr Distribution Model

The SEVERITY Procedure			
Distribution Information			
Name	Burr		
Description	Burr Distribution		
Number of Distribution Parameters	3		
Number of Regression Parameters	4

x2	Redundant	.	.
x3	-0.14056	-709.78271	709.78271
x4	0.27064	-709.78271	709.78271
x5	-0.23230	-709.78271	709.78271
Convergence Status for Burr Distribution			
Needs more than 50 iterations.			
Optimization Summary for Burr Distribution			
Optimization Technique	Trust Region		
Number of Iterations	50		
Number of Function Evaluations	130		
Log Likelihood	-306.40430		

The following PROC SEVERITY step uses the NLOPTIONS statement to change the convergence criterion and the limits on the iterations and function evaluations, exclude the lognormal and Pareto distributions that have been confirmed previously to fit the data poorly, and exclude the redundant regressor X2 from the model:

```

/*--- Enable ODS graphics processing ---*/
ods graphics on;

/*--- Refit and compare models with higher limit on iterations ---*/
proc severity data=testnorm_reg print=all plots=pp;
  model y=x1 x3-x5;
  dist Normal_s;
  dist burr;
  dist weibull;
  nloptions absfconv=2.0e-5 maxiter=100 maxfunc=500;
run;

```

The results shown in [Output 22.2.3](#) indicate that the Burr distribution has now converged and that the Burr and Weibull distributions have an almost identical fit for the data. The NORMAL_S distribution is still the best distribution according to the likelihood-based criteria.

Output 22.2.3 Summary of Results after Changing Maximum Number of Iterations

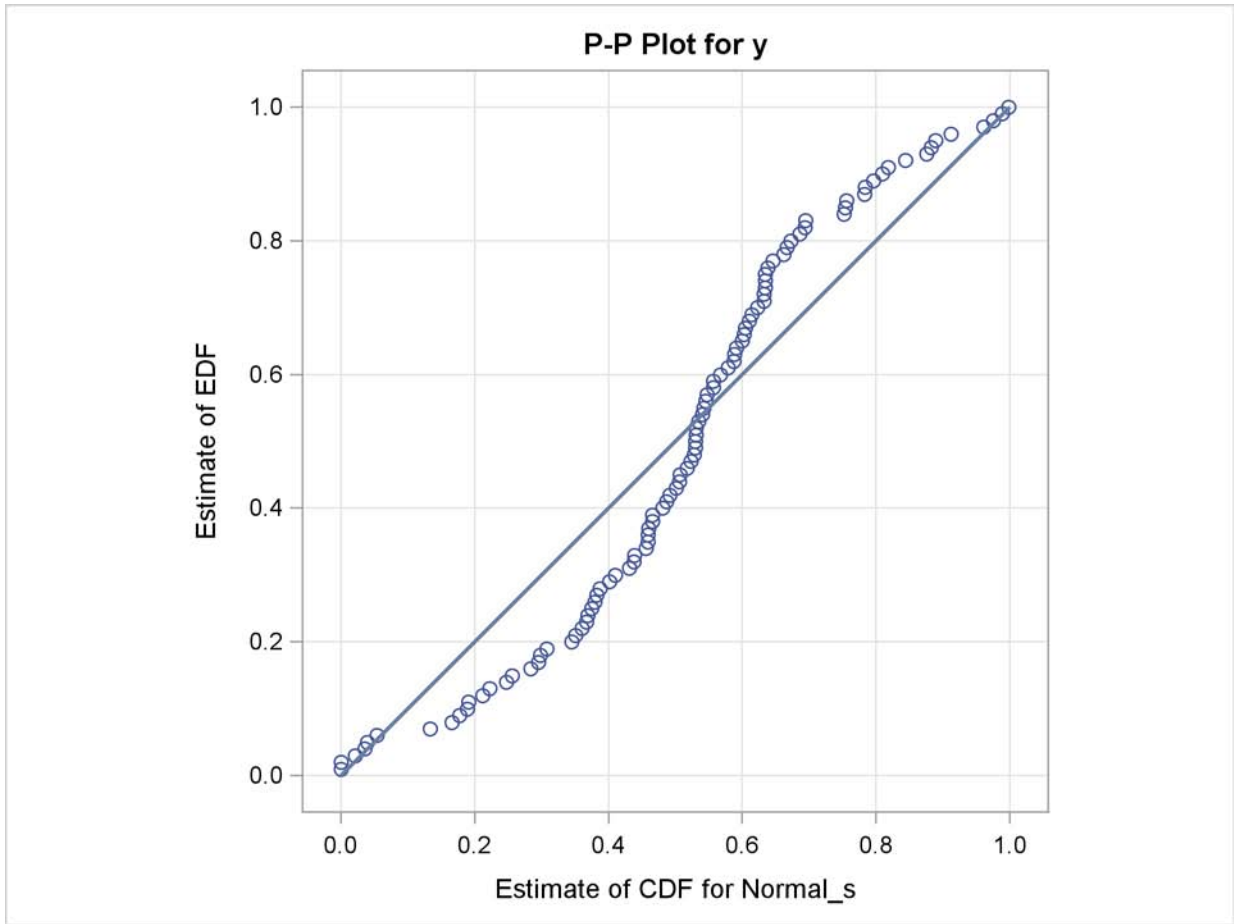

The SEVERITY Procedure					
Input Data Set					
Name		WORK.TESTNORM_REG			
Model Selection Table					
Distribution	Converged	-2 Log Likelihood		Selected	
Normal_s	Yes	603.95786		Yes	
Burr	Yes	612.78605		No	
Weibull	Yes	612.77496		No	
All Fit Statistics Table					
Distribution	-2 Log Likelihood	AIC	AICC	BIC	KS
Normal_s	603.95786*	615.95786*	616.86108*	631.58888*	1.56822*
Burr	612.78605	626.78605	628.00344	645.02224	1.59154
Weibull	612.77496	624.77496	625.67819	640.40598	1.59176
All Fit Statistics Table					
Distribution	AD	CvM			
Normal_s	4.25257	0.75658			
Burr	4.22313*	0.71959*			
Weibull	4.22441	0.71985			

The comparison of the PDF estimates of all the candidates is shown in [Output 22.2.4](#). Each plotted PDF estimate is an average computed over the N PDF estimates that are obtained with the scale parameter determined by each of the N observations in the input data set. The PDF plot shows that the Burr and Weibull models result in almost identical estimates. All the estimates have a slight left skew with the mode closer to $Y=25$, which is the mean of the simulated sample.

Output 22.2.4 Comparison of EDF and CDF Estimates of the Fitted Models

The P-P plots for the Normal_s and Burr distributions are shown in [Output 22.2.5](#). These plots show how the EDF estimates compare against the CDF estimates. Each plotted CDF estimate is an average computed over the N CDF estimates that are obtained with the scale parameter determined by each of the N observations in the input data set. Comparing the P-P plots of Normal_s and Burr distributions indicates that both fit the data almost similarly, but the Burr distribution fits the right tail slightly better, which explains why the EDF-based statistics prefer it over the Normal_s distribution.

Output 22.2.5 Comparison of EDF and CDF Estimates of the Fitted Models

Output 22.2.5 continued

Example 22.3: Defining a Model for Mixed Tail Distributions

In some applications, a few severity values tend to be extreme as compared to the typical values. The extreme values represent the worst case scenarios and cannot be discarded as outliers. Instead, their distribution must be modeled to prepare for their occurrences. In such cases, it is often useful to fit one distribution to the non-extreme values and another distribution to the extreme values. The *mixed tail* distribution mixes two distributions: one for the *body* region, which contains the non-extreme values, and another for the *tail* region, which contains the extreme values. The tail distribution is typically a generalized Pareto distribution (GPD), because it is usually good for modeling the conditional excess severity above a threshold. The body distribution can be any distribution. The following definitions are used in describing a generic formulation of a mixed tail distribution:

- $g(x)$ PDF of the body distribution
- $G(x)$ CDF of the body distribution
- $h(x)$ PDF of the tail distribution
- $H(x)$ CDF of the tail distribution

θ	scale parameter for the body distribution
Ω	set of nonscale parameters for the body distribution
ξ	shape parameter for the GPD tail distribution
x_r	normalized value of the response variable at which the tail starts
p_n	mixing probability

Given these notations, the PDF $f(x)$ and the CDF $F(x)$ of the mixed tail distribution are defined as

$$f(x) = \begin{cases} \frac{p_n}{G(x_b)}g(x) & \text{if } x \leq x_b \\ (1 - p_n)h(x - x_b) & \text{if } x > x_b \end{cases}$$

$$F(x) = \begin{cases} \frac{p_n}{G(x_b)}G(x) & \text{if } x \leq x_b \\ p_n + (1 - p_n)H(x - x_b) & \text{if } x > x_b \end{cases}$$

where $x_b = \theta x_r$ is the value of the response variable at which the tail starts.

These definitions indicate the following:

- The body distribution is conditional on $X \leq x_b$, where X denotes the random response variable.
- The tail distribution is the generalized Pareto distribution of the $(X - x_b)$ values.
- The probability that a response variable value belongs to the body is p_n . Consequently the probability that the value belongs to the tail is $(1 - p_n)$.

The parameters of this distribution are θ , Ω , ξ , x_r , and p_n . The scale of the GPD tail distribution θ_t is computed as

$$\theta_t = \frac{G(x_b; \theta, \Omega) (1 - p_n)}{g(x_b; \theta, \Omega) p_n} = \theta \frac{G(x_r; \theta = 1, \Omega) (1 - p_n)}{g(x_r; \theta = 1, \Omega) p_n}$$

The parameter x_r is typically estimated using a tail index estimation algorithm. One such algorithm is the Hill's algorithm (Danielsson et al. 2001), which is implemented by the predefined utility function SVRTUTIL_HILLCUTOFF available to you in the SASHELP.SVRTDIST library. The algorithm and the utility function are described in detail in the section "Predefined Utility Functions" on page 1537. The function computes an estimate of x_b , which can be used to compute an estimate of x_r because $x_r = x_b/\hat{\theta}$, where $\hat{\theta}$ is the estimate of the scale parameter of the body distribution.

The parameter p_n is typically determined by the domain expert based on the fraction of losses that are expected to belong to the tail.

The following SAS statements define the LOGNGPD distribution model for a mixed tail distribution with the lognormal distribution as the body distribution and GPD as the tail distribution:

```

/*----- Define Lognormal Body-GPD Tail Mixed Distribution -----*/
proc fcmp library=sashelp.svrtdist outlib=work.sevexmpl.models;
    function LOGNGPD_DESCRIPTION() $256;
        length desc $256;

```

```

desc1 = "Lognormal Body-GPD Tail Distribution.";
desc2 = " Mu, Sigma, and Xi are free parameters.";
desc3 = " Xr and Pn are constant parameters.";
desc = desc1 || desc2 || desc3;
return(desc);
endsub;

function LOGNGPD_SCALETRANSFORM() $3;
length xform $3;
xform = "LOG";
return (xform);
endsub;

subroutine LOGNGPD_CONSTANTPARM(Xr,Pn);
endsub;

function LOGNGPD_PDF(x, Mu, Sigma, Xi, Xr, Pn);
cutoff = exp(Mu) * Xr;
p = CDF('LOGN', cutoff, Mu, Sigma);
if (x < cutoff + constant('MACEPS')) then do;
return ((Pn/p)*PDF('LOGN', x, Mu, Sigma));
end;
else do;
gpd_scale = p*((1-Pn)/Pn)/PDF('LOGN', cutoff, Mu, Sigma);
h = (1+Xi*(x-cutoff)/gpd_scale)**(-1-(1/Xi))/gpd_scale;
return ((1-Pn)*h);
end;
endsub;

function LOGNGPD_CDF(x, Mu, Sigma, Xi, Xr, Pn);
cutoff = exp(Mu) * Xr;
p = CDF('LOGN', cutoff, Mu, Sigma);
if (x < cutoff + constant('MACEPS')) then do;
return ((Pn/p)*CDF('LOGN', x, Mu, Sigma));
end;
else do;
gpd_scale = p*((1-Pn)/Pn)/PDF('LOGN', cutoff, Mu, Sigma);

endsub;

subroutine LOGNGPD_LOWERBOUNDS (Mu, Sigma, Xi, Xr, Pn);
    outargs Mu, Sigma, Xi, Xr, Pn;

    Mu    = .; /* Mu has no lower bound */
    Sigma = 0; /* Sigma > 0 */
    Xi    = 0; /* Xi > 0 */
endsub;
quit;

```

The following points should be noted regarding the LOGNGPD definition:

- The parameters x_r and p_n are not estimated with the maximum likelihood method used by PROC SEVERITY, so you need to specify them as *constant* parameters by defining the `dist_CONSTANTPARM` subroutine. The signature of LOGNGPD_CONSTANTPARM subroutine lists only the constant parameters X_r and P_n .
- The parameter x_r is estimated by first using the SVRTUTIL_HILLCUTOFF utility function to compute an estimate of the cutoff point \hat{x}_b and then computing $x_r = \hat{x}_b/e^{\hat{\mu}}$. If SVRTUTIL_HILLCUTOFF fails to compute a valid estimate, then the SVRTUTIL_PERCENTILE utility function is used to set \hat{x}_b to the p_n th percentile of the data. The parameter p_n is fixed to 0.8.

- The SASHELP.SVRTDIST library is specified with the LIBRARY= option in the PROC FCMP statement to enable the LOGNGPD_PARMINIT subroutine to use the predefined utility functions (SVRTUTIL_HILLCUTOFF and SVRTUTIL_PERCENTILE) and parameter initialization subroutines (LOGN_PARMINIT and GPD_PARMINIT).
- The LOGNGPD_LOWERBOUNDS subroutine defines the lower bounds for all parameters. This subroutine is required because the parameter μ has a non-default lower bound. The bounds for σ and ξ must be specified. If they are not specified, they are returned as missing values, which get interpreted as having no lower bound by PROC SEVERITY. You need not specify any bounds for the constant parameters X_r and P_n , because they are not subject to optimization.

The following DATA step statements simulate a sample from a mixed tail distribution with a lognormal body and GPD tail. The parameter p_n is fixed to 0.8, the same value used in the LOGNGPD_PARMINIT subroutine defined previously:

```

/*----- Simulate a sample for the mixed tail distribution -----*/
data testmixdist(keep=y label='Lognormal Body-GPD Tail Sample');
  call streaminit(45678);
  label y='Response Variable';
  N = 100;
  Mu = 1.5;
  Sigma = 0.25;
  Xi = 1.5;
  Pn = 0.8;

  /* Generate data comprising the lognormal body */
  Nbody = N*Pn;
  do i=1 to Nbody;
    y = exp(Mu) * rand('LOGNORMAL')**Sigma;
    output;
  end;

  /* Generate data comprising the GPD tail */
  cutoff = quantile('LOGNORMAL', Pn, Mu, Sigma);
  gpd_scale = (1-Pn) / pdf('LOGNORMAL', cutoff, Mu, Sigma);
  do i=Nbody+1 to N;
    y = cutoff + ((1-rand('UNIFORM'))**(-Xi) - 1)*gpd_scale/Xi;
    output;
  end;
run;

```

The following statements use PROC SEVERITY to fit the LOGNGPD distribution model to the simulated sample. They also fit three other predefined distributions (BURR, LOGN, and GPD). The final parameter estimates are written to the WORK.PARMEST data set.

```

/*--- Enable ODS graphics processing ---*/
ods graphics on;

/*--- Set the search path for functions defined with PROC FCMP ---*/
options cmplib=(work.sevexmpl);

/*----- Fit LOGNGPD model with PROC SEVERITY -----*/
proc severity data=testmixdist print=all plots(histogram kernel)=all
  outest=parmest;
  model y;
  dist logngpd;
  dist burr;
  dist logn;
  dist gpd;
run;

```

Some of the results prepared by PROC SEVERITY are shown in [Output 22.3.1](#) through [Output 22.3.4](#). The model selection table of [Output 22.3.1](#) indicates that all models converged. The table in [Output 22.3.1](#) shows that the model with LOGNGPD distribution has the best fit according to almost all the statistics of fit. The Burr distribution model is the closest contender to the LOGNGPD model, but the GPD distribution model fits the data very poorly.

Output 22.3.1 Summary of Fitting Mixed Tail Distribution

The SEVERITY Procedure				
Input Data Set				
Name	WORK.TESTMIXDIST			
Label	Lognormal Body-GPD Tail Sample			
Model Selection Table				
Distribution	Converged	-2 Log Likelihood	Selected	
logngpd	Yes	418.78232	Yes

Gpd	Yes	558.13444	No	

Output 22.3.1 *continued*

All Fit Statistics Table					
Distribution	-2 Log Likelihood	AIC	AICC	BIC	KS
logngpd	418.78232*	428.78232*	429.42062*	441.80817	0.62140*
Burr	424.93728	430.93728	431.18728	438.75280*	0.71373
Logn	459.43471	463.43471	463.55842	468.64505	1.55267
Gpd	558.13444	562.13444	562.25815	567.34478	3.43470

All Fit Statistics Table		
Distribution	AD	CvM
logngpd	0.31670*	0.04972*
Burr	0.57649	0.07860
Logn	3.27122	0.48448
Gpd	16.74156	3.31860

The plots in [Output 22.3.2](#) show that both the lognormal and GPD distributions fit the data poorly, GPD being the worst. The Burr distribution fits the data as well as the LOGNGPD mixed distribution in the body region, but has a poorer fit in the tail region than the LOGNGPD mixed distribution.

Output 22.3.2 Comparison of the CDF and PDF Estimates of the Fitted Models

Output 22.3.2 continued

The P-P plots of [Output 22.3.3](#) provide a better visual confirmation that the LOGNGPD distribution fits the tail region better than the Burr distribution.

Output 22.3.3 P-P Plots for the LOGNGPD and BURR Distribution Models

Output 22.3.3 continued

The detailed results for the LOGNGPD distribution are shown in [Output 22.3.4](#). The initial values table indicates the values computed by LOGNGPD_PARMINIT subroutine for the Xr and Pn parameters. It also uses the bounds columns to indicate the constant parameters. The last table in the figure shows the final parameter estimates. The estimates of all free parameters are significantly different than 0. As expected, the final estimates of the constant parameters Xr and Pn have not changed from their initial values.

Output 22.3.4 Detailed Results for the LOGNGPD Distribution

Parameter Estimates for logngpd Distribution				
Parameter	Estimate	Standard Error	t Value	Approx Pr > t
Mu	1.57921	0.06426	24.57	<.0001
Sigma	0.31868	0.04459	7.15	<.0001
Xi	1.03771	0.38205	2.72	0.0078
Xr	1.27395	Constant	.	.
Pn	0.80000	Constant	.	.

The following SAS statements use the parameter estimates to compute the value where the tail region is estimated to start ($x_b = e^{\hat{\mu}} \hat{x}_r$) and the scale of the GPD tail distribution ($\theta_t = \frac{G(x_b)(1-p_n)}{g(x_b)p_n}$):

```

/*----- Compute tail cutoff and tail distribution's scale -----*/
data xb_thetat(keep=x_b theta_t);
  set parmesest(wher=(MODEL='logngpd' and _TYPE_='EST'));
  x_b = exp(Mu) * Xr;
  theta_t = (CDF('LOGN', x_b, Mu, Sigma) / PDF('LOGN', x_b, Mu, Sigma)) *
            ((1-Pn) / Pn);
run;

proc print data=xb_thetat noobs;
run;

```

Output 22.3.5 Start of the Tail and Scale of the GPD Tail Distribution

Obs	x_b	theta_t
1	6.18005	1.27865

The computed values of x_b and θ_t are shown as x_b and $theta_t$ in [Output 22.3.5](#). Equipped with this additional derived information, you can now interpret the results of fitting the mixed tail distribution as follows:

- The tail starts at $y \approx 6.18$. The primary benefit of using the scale-normalized cutoff (x_r) as the constant parameter instead of using the actual cutoff (x_b) is that the absolute cutoff gets optimized by virtue of optimizing the scale of the body region ($\theta = e^{\mu}$).
- The values $y \leq 6.18$ follow the lognormal distribution with parameters $\mu \approx 1.58$ and $\sigma \approx 0.32$. These parameter estimates are reasonably close to the parameters used for simulating the sample.
- The values $y_t = y - 6.18$ ($y_t > 0$) follow the GPD distribution with scale $\theta_t \approx 1.28$ and shape $\xi \approx 1.04$.

Overview: SIMILARITY Procedure

The SIMILARITY procedure computes similarity measures associated with time-stamped data, time series, and other sequentially ordered numeric data. PROC SIMILARITY computes similarity measures for time-stamped transactional data (transactions) with respect to time by accumulating the data into a time series format, and it computes similarity measures for sequentially ordered numeric data (sequences) by respecting the ordering of the data.

Given two ordered numeric sequences (input and target), a similarity measure is a metric that measures the distance between the input and target sequences while taking into account the ordering of the data. The SIMILARITY procedure computes similarity measures between an input sequence and a target sequence, in addition to similarity measures that “slide” the target sequence with respect to the input sequence. The “slides” can be by observation index (sliding-sequence similarity measures) or by seasonal index (seasonal-sliding-sequence similarity measures).

In order to compare the raw input and the raw target time-stamped data, the raw data must be accumulated to a time series format. After the input and target time series are formed, the two accumulated time series can be compared as two ordered numeric sequences.

For raw time-stamped data, after the transactional data are accumulated to form time series and any missing values are interpreted, each accumulated time series can be functionally transformed, if desired. Transformations are useful when you want to stabilize the time series before computing the similarity measures. Transformations performed by the SIMILARITY procedure include the following:

- log (LOG)
- square-root (SQRT)
- logistic (LOGISTIC)
- Box-Cox (BOXCOX)
- user-defined transformations

Each time series can be transformed further by using simple differencing or seasonal differencing or both. Additional time series transformations can be performed by using various time series transformation and analysis techniques provided by this procedure or other SAS/ETS procedures.

After optionally transforming each time series, the accumulated and transformed time series can be stored in an output data set (OUT= data set).

After optional accumulation and transformation, each of these time series are the “working series,” which can now be analyzed as sequences of numeric data. Each of these sequences can be a target sequence, an input sequence, or both a target and an input sequence. Throughout the remainder of this chapter, the term “original sequence” applies to both the original input and target sequence. The term “working sequence” applies to a version of both the original input and target sequence under investigation.

Each original sequence can be normalized prior to similarity analysis. Normalizations are useful when you want to compare the “shape” or “profile” of the time series. Normalizations performed by the SIMILARITY procedure include the following:

- standard (STANDARD)
- absolute (ABSOLUTE)
- user-defined normalizations

After each original sequence is optionally normalized, each working input sequence can be scaled to the target sequence prior to similarity analysis. Scaling is useful when you want to compare the input sequence to the target sequence while discounting the variation of the target sequence. Input sequence scaling performed by the SIMILARITY procedure include the following:

- standard (STANDARD)
- absolute (ABSOLUTE)
- user-defined scaling

After the working input sequence is optionally scaled to the target sequence, similarity measures can be computed. Similarity measures computed by the SIMILARITY procedure include:

- squared deviation (SQRDEV)
- absolute deviation (ABSDEV)
- mean square deviation (MSQRDEV)
- mean absolute deviation (MABSDEV)
- user-defined similarity measures

In computing the similarity measure between two time series, tasks are needed for transforming time series, normalizing sequences, scaling sequences, and computing metrics or measures. The SIMILARITY procedure provides built-in routines to perform these tasks. The SIMILARITY procedure also enables you to extend the procedure with user-defined routines.

All results of the similarity analysis can be stored in output data sets, printed, or graphed using the Output Delivery System (ODS).

The SIMILARITY procedure can process large amounts of time-stamped transactional data, time series, or sequential data. Therefore, the analysis results are useful for large-scale time series analysis, analogous time series forecasting, new product forecasting, or time series (temporal) data mining.

The SAS/ETS EXPAND procedure can be used for frequency conversion and transformations of time series. The TIMESERIES procedure can be used for large-scale time series analysis. The SAS/STAT DISTANCE procedure can be used to compute various measures of distance, dissimilarity, or similarity between observations (rows) of a SAS data set.

Getting Started: SIMILARITY Procedure

This section outlines the use of the SIMILARITY procedure and gives a cursory description of some of the analysis techniques that can be performed on time-stamped transactional data, time series, or sequentially ordered numeric data.

Given an input data set that contains numerous transaction variables recorded over time at no specific frequency, the SIMILARITY procedure can form equally spaced input and target time series as follows:

```
PROC SIMILARITY DATA=<input-data-set>
                OUT=<output-data-set>
                OUTSUM=<summary-data-set>;
  ID <time-ID-variable> INTERVAL=<frequency>
    ACCUMULATE=<statistic>;
  INPUT <input-time-stamp-variables>;
  TARGET <target-time-stamp-variables>;
RUN;
```

The SIMILARITY procedure forms time series from the input time-stamped transactional data. It can provide results in output data sets or in other output formats using the Output Delivery System (ODS). The examples in this section are more fully illustrated in the section “[Examples: SIMILARITY Procedure](#)” on page 1633.

Time-stamped transactional data are often recorded at no fixed interval. Analysts often want to use time series analysis techniques that require fixed-time intervals. Therefore, the transactional data must be accumulated to form a fixed-interval time series.

Suppose that a bank wants to analyze the transactions that are associated with each of its customers over time. Further, suppose that the data set WORK.TRANSACTIONS contains three variables that are related to the customer transactions (CUSTOMER, DATE, and WITHDRAWAL) and one variable that contains an example fraudulent behavior (FRAUD).

The following statements illustrate how to use the SIMILARITY procedure to accumulate time-stamped transactional data to form a daily time series based on the accumulated daily totals of each type of transaction (WITHDRAWALS and FRAUD):

```
proc similarity data=transactions out=timedata;
  by customer;
  id date interval=day accumulate=total;
  input withdrawals;
  target fraud;
run;
```

The OUT=TIMEDATA option specifies that the resulting time series data for each customer are to be stored in the data set WORK.TIMEDATA. The INTERVAL=DAY option specifies that the transactions are to be accumulated on a daily basis. The ACCUMULATE=TOTAL option specifies that the sum of the transactions are to be accumulated. After the transactional data are accumulated into a time series format, the time series data can be normalized so that the “shape” or “profile” is analyzed.

For example, the following statements build on the previous statements and demonstrate normalization of the accumulated time series:

```
proc similarity data=transactions out=timedata;
  by customer;
  id date interval=day accumulate=total;
  input withdrawals / NORMALIZE=STANDARD;
  target fraud      / NORMALIZE=STANDARD;
run;
```

The NORMALIZE=STANDARD option specifies that each accumulated time series observation is normalized by subtracting the mean and then dividing by the standard deviation of the accumulated time series. The WORK.TIMEDATA data set now contains the accumulated and normalized time series data for each customer.

After the transactional data are accumulated into a time series format and normalized to a mean of zero and standard deviation of one, similarity analysis can be performed on the accumulated and normalized time series.

For example, the following statements build on the previous statements and demonstrate similarity analysis of the accumulated and normalized time series:

```
proc similarity data=transactions
  out=timedata OUTSUM=SUMMARY;
  by customer;
  id date interval=day accumulate=total;
  input withdrawals / normalize=standard;
  target fraud      / normalize=standard MEASURE=MABSDEV;
run;
```

The MEASURE=MABSDEV option specifies the accumulated and normalized time series data that are associated with the variables WITHDRAWALS and FRAUD are to be compared by using

mean absolute deviation. The OUTSUM=SUMMARY option specifies that the similarity analysis summary for each customer is to be stored in the data set WORK.SUMMARY.

Syntax: SIMILARITY Procedure

The following statements are used with the SIMILARITY procedure.

```
PROC SIMILARITY options ;
  BY variables ;
  ID variable INTERVAL=interval options ;
  FCMPOPT options ;
  INPUT variable-list / options ;
  TARGET variable-list / options ;
```

Functional Summary

The statements and options that control the SIMILARITY procedure are summarized in the following table.

Table 23.1 SIMILARITY Functional Summary

Description	Statement	Option

Specifies the ordering of the processing of the input and target variables	PROC SIMILARITY	ORDER=

PROC SIMILARITY Statement

PROC SIMILARITY *options* ;

The following options can be used in the PROC SIMILARITY statement.

DATA=*SAS-data-set*

names the SAS data set that contains the time series, transactional, or sequence input data for the procedure. If the DATA= option is not specified, the most recently created SAS data set is used.

ORDER=*order-option*

specifies the order in which the variables listed in the INPUT and TARGET statements are to be processed. This ordering affects the OUTSEQUENCE=, OUTPATH=, OUTMEASURE=, and OUTSUM= data sets, in addition to the printed and graphical output. The SORTNAMES option also affects the ordering of the analysis. You must specify one of the following *order-options*:

INPUT	specifies that each INPUT variable be processed and then the TARGET variables be processed. The results are stored and printed based only on the INPUT variables.
INPUTTARGET	specifies that each INPUT variable be processed and then the TARGET variables be processed. The results are stored and printed based on both the INPUT and TARGET variables. This is the default.
TARGET	specifies that each TARGET variable be processed and then the INPUT variables be processed. The results are stored and printed based only on the TARGET variables.
TARGETINPUT	specifies that each TARGET variable be processed and then the INPUT variables be processed. The results are stored and printed based on both the TARGET and INPUT variables.

OUT=*SAS-data-set*

names the output data set to contain the time series variables specified in the subsequent INPUT and TARGET statements. If an ID variable is specified in the ID statement, it is also included in the OUT= data set. The values are accumulated based on the ID statement INTERVAL= option or the ACCUMULATE= options or both. The values are transformed based on the INPUT or TARGET statement TRANSFORM=, DIF=, and SDIF= options in this order. The OUT= data set is particularly useful when you want to further analyze, model, or forecast the resulting time series with other SAS/ETS procedures.

OUTMEASURE=*SAS-data-set*

names the output data set to contain the detailed similarity measures by time ID value. The form of the OUTMEASURE= data set is determined by the PROC SIMILARITY statement SORTNAMES and ORDER= options.

OUTPATH=*SAS-data-set*

names the output data set to contain the path used to compute the similarity measures for

each slide and warp. The form of the OUTPATH= data set is determined by the PROC SIMILARITY statement SORTNAMES and ORDER= options. If a user-defined similarity measure is specified, the path cannot be determined; therefore, the OUTPATH= data set does not contain information related to this measure.

OUTSEQUENCE=*SAS-data-set*

names the output data set to contain the sequences used to compute the similarity measures for each slide and warp. The form of the OUTSEQUENCE= data set is determined by the PROC SIMILARITY statement SORTNAMES and ORDER= options.

OUTSUM=*SAS-data-set*

names the output data set to contain the similarity measure summary. The OUTSUM= data set is particularly useful when analyzing large numbers of series and only the summary of the results are needed. The form of the OUTSUM= data set is determined by the PROC SIMILARITY statement SORTNAMES and ORDER= options.

PLOTS=*option*

PLOTS=(*options ...*)

specifies the graphical output desired. To specify multiple *options*, separate them by spaces and enclose the group in parentheses. By default, the SIMILARITY procedure produces no graphical output. The following graphical *options* are available:

COSTS	plots graphics for time warp costs.
DISTANCES	plots graphics for similarity absolute and relative distances (OUTPATH= data set).
INPUTS	plots graphics for input variable time series (OUT= data set).
MAPS	plots graphics for time warp maps (OUTPATH= data set).
MEASURES	plots graphics for similarity measures (OUTMEASURE= data set).
NORMALIZED	plots graphics for both the input and target variable normalized sequence. These plots are displayed only when the INPUT or TARGET statement NORMALIZE= option is specified.
PATHS	plots time warp paths graphics (OUTPATH= data set).
SCALED	plots graphics for both the input variable scaled sequence. These plots are displayed only when the INPUT statement SCALE= option is specified.
SEQUENCES	plots graphics for both the input and target variable sequence (OUTSEQUENCE= data set).
TARGETS	plots graphics for the target variable time series (OUT= data set).
WARPS	plots graphics for time warps (OUTPATH= data set).
ALL	is the same as PLOTS=(INPUTS TARGETS SEQUENCES NORMALIZED SCALED DISTANCES PATHS MAPS WARPS COST MEASURES).

PRINT=option

PRINT=(options ...)

specifies the printed output desired. To specify multiple *options*, separate them by spaces and enclose the group in parentheses. By default, the SIMILARITY procedure produces no printed output. The following printing options are available:

DESCSTATS	prints the descriptive statistics for the working time series.
PATHS	prints the path statistics table. If a user-defined similarity measure is specified, the path cannot be determined; therefore, the PRINT=PATHS table is not printed for this measure.
COSTS	prints the cost statistics table.
WARPS	prints the warp summary table.
SLIDES	prints the slides summary table.
SUMMARY	prints the similarity measure summary table.
ALL	is the same as PRINT=(DESCSTATS PATHS COSTS WARPS SLIDES SUMMARY).

PRINTDETAILS

specifies that the output requested with the PRINT= option be printed in greater detail.

SEASONALITY=integer

specifies the length of the seasonal cycle where *integer* ranges from one to 10,000. For example, SEASONALITY=3 means that every group of three time periods forms a seasonal cycle. By default, the length of the seasonal cycle is 1 (no seasonality) or the length implied by the INTERVAL= option specified in the ID statement. For example, INTERVAL=MONTH implies that the length of the seasonal cycle is 12.

SORTNAMES

specifies that the variables specified in the INPUT and TARGET statements be processed in alphabetical order of the variable names. By default, the SIMILARITY procedure processes the variables in the order in which they are listed. The ORDER= option also affects the ordering in which the analysis is performed.

BY Statement

A BY statement can be used with PROC SIMILARITY to obtain separate dummy variable definitions for groups of observations defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.

- Specify the option NOTSORTED or DESCENDING in the BY statement for the SIMILARITY procedure. The NOTSORTED option does not mean that the data are unsorted, but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY-group processing, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FCMPOPT Statement

FCMPOPT *options* ;

The FCMPOPT statement specifies the following *options* that are related to user-defined functions and subroutines:

QUIET=ON | OFF

specifies whether the nonfatal errors and warnings that are generated by the user-defined SAS language functions and subroutines are printed to the log. Nonfatal errors are usually associated with operations with missing values. The default is QUIET=ON.

TRACE=ON | OFF

specifies whether the user-defined SAS language functions and subroutines tracings are printed to the log. Tracings are the results of every operation executed. This option is generally used for debugging. The default is TRACE=OFF.

ID Statement

ID *variable* **INTERVAL=** *interval options* ;

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date, time, or datetime values. In addition, the ID statement specifies the (desired) frequency associated with the time series. The ID statement options also specify how the observations are accumulated and how the time ID values are aligned to form the time series. The options specified affect all variables listed in subsequent INPUT and TARGET statements. If an ID statement is specified, the INTERVAL= option must also be specified. The other ID statement options are optional. If an ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID.

The following options can be used with the ID statement:

ACCUMULATE=*option*

specifies how the data set observations are accumulated within each time period. The frequency

(width of each time interval) is specified by the INTERVAL= option. The ID variable contains the time ID values. Each time ID variable value corresponds to a specific time period. The accumulated values form the time series, which is used in subsequent analysis.

The ACCUMULATE= option is particularly useful when there are zero or more than one input observations that coincide with a particular time period (for example, time-stamped transactional data). The EXPAND procedure offers additional frequency conversions and transformations that can also be useful in creating a time series.

The following *options* determine how the observations are accumulated within each time period based on the ID variable and the frequency specified by the INTERVAL= option:

NONE	No accumulation occurs; the ID variable values must be equally spaced with respect to the frequency. This is the default option.
TOTAL	Observations are accumulated based on the total sum of their values.
AVERAGE AVG	Observations are accumulated based on the average of their values.
MINIMUM MIN	Observations are accumulated based on the minimum of their values.
MEDIAN MED	Observations are accumulated based on the median of their values.
MAXIMUM MAX	Observations are accumulated based on the maximum of their values.
N	Observations are accumulated based on the number of nonmissing observations.
NMISS	Observations are accumulated based on the number of missing observations.
NOBS	Observations are accumulated based on the number of observations.
FIRST	Observations are accumulated based on the first of their values.
LAST	Observations are accumulated based on the last of their values.
STDDEV STD	Observations are accumulated based on the standard deviation of their values.
CSS	Observations are accumulated based on the corrected sum of squares of their values.
USS	Observations are accumulated based on the uncorrected sum of squares of their values.

If the ACCUMULATE= option is specified, the SETMISSING= option is useful for specifying how accumulated missing values are treated. If missing values should be interpreted as zero, then SETMISSING=0 should be used. The section “[Details: SIMILARITY Procedure](#)” on page 1610 describes accumulation in greater detail.

ALIGN=option

controls the alignment of SAS dates that are used to identify output observations. The

ALIGN= option accepts the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. ALIGN=BEGINNING is the default.

END=option

specifies a SAS date, datetime, or time value that represents the end of the data. If the last time ID variable value is less than the END= value, the series is extended with missing values. If the last time ID variable value is greater than the END= value, the series is truncated. For example, END="&sysdate"D uses the automatic macro variable SYSDATE to extend or truncate the series to the current date. The START= and END= options can be used to ensure that data that are associated within each BY group contain the same number of observations.

FORMAT=format

specifies the SAS format for the time ID values. If the FORMAT= option is not specified, the default format is implied by the INTERVAL= option. For example, FORMAT=DATE9. specifies that the DATE9. SAS format be used. Notice that the terminating "." is required when specifying a SAS format.

INTERVAL= interval

specifies the frequency of the accumulated time series. For example, if the input data set consists of quarterly observations, then INTERVAL=QTR should be used. If the SEASONALITY= option is not specified, the length of the seasonal cycle is implied from the INTERVAL= option. For example, INTERVAL=QTR implies a seasonal cycle of length 4. If the ACCUMULATE= option is also specified, the INTERVAL= option determines the time periods for the accumulation of observations.

NOTSORTED

specifies that the time ID values are not in sorted order. The SIMILARITY procedure sorts the data with respect to the time ID prior to analysis if the NOTSORTED option is specified.

SETMISSING=option | number

specifies how missing values (either actual or accumulated) are interpreted in the accumulated time series. If a *number* is specified, missing values are set to that number. If a missing value indicates an unknown value, the SETMISSING= option should not be used. If a missing value indicates no value, then SETMISSING=0 should be used. You typically use SETMISSING=0 for transactional data, because no recorded data usually implies no activity. The following *options* can also be used to determine how missing values are assigned:

MISSING	Missing values are set to missing. This is the default option.
AVERAGE AVG	Missing values are set to the accumulated average value.
MINIMUM MIN	Missing values are set to the accumulated minimum value.
MEDIAN MED	Missing values are set to the accumulated median value.
MAXIMUM MAX	Missing values are set to the accumulated maximum value.
FIRST	Missing values are set to the accumulated first nonmissing value.
LAST	Missing values are set to the accumulated last nonmissing value.
PREVIOUS PREV	Missing values are set to the previous period's accumulated nonmissing value. Missing values at the beginning of the accumulated series remain missing.

NEXT Missing values are set to the next period's accumulated nonmissing value. Missing values at the end of the accumulated series remain missing.

START=option

specifies a SAS date, datetime, or time value that represents the beginning of the data. If the first time ID variable value is greater than the START= value, the series is prepended with missing values. If the first time ID variable value is less than the START= value, the series is truncated. The START= and END= options can be used to ensure that data that are associated with each BY group contain the same number of observations.

ZEROMISS=option

specifies how beginning and ending zero values (either actual or accumulated) are interpreted in the accumulated time series. The following *options* can also be used to determine how beginning and ending zero values are assigned:

NONE	Beginning and ending zeros are unchanged. This is the default.
LEFT	Beginning zeros are set to missing.
RIGHT	Ending zeros are set to missing.
BOTH	Both beginning and ending zeros are set to missing.

If the accumulated series is all missing or zero, the series is not changed.

INPUT Statement

INPUT *variable-list* < / *options* > ;

The INPUT statement lists the input numeric variables in the DATA= data set whose values are to be accumulated to form the time series or represent ordered numeric sequences (when no ID statement is specified).

An input data set variable can be specified in only one INPUT or TARGET statement. Any number of INPUT statements can be used. The following *options* can be used with an INPUT statement:

ACCUMULATE=option

specifies how the data set observations are accumulated within each time period for the variables listed in the INPUT statement. If the ACCUMULATE= option is not specified in the INPUT statement, accumulation is determined by the ACCUMULATE= option of the ID statement. If the ACCUMULATE= option is not specified in the ID statement or the INPUT statement, no accumulation is performed. See the ID statement ACCUMULATE= option for more details.

DIF=(numlist)

specifies the differencing to be applied to the accumulated time series. The list of differencing orders must be separated by spaces or commas. For example, DIF=(1,3) specifies first,

then third order, differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the DIF= option. Simple differencing is useful when you want to detrend the time series before computing the similarity measures.

NORMALIZE=option

specifies the sequence normalization to be applied to the working input sequence. The following normalization *options* are provided:

NONE	No normalization is applied. This option is the default.
ABSOLUTE	Absolute normalization is applied.
STANDARD	Standard normalization is applied.
<i>User-Defined</i>	Normalization is computed by a user-defined subroutine that is created using the FCMP procedure, where <i>User-Defined</i> is the subroutine name.

Normalization is applied to the working input sequence, which can be a subset of the working input time series if the SLIDE=INDEX or SLIDE=SEASON option is specified.

SCALE=option

specifies the scaling of the working input sequence with respect to the working target sequence. Scaling is performed after normalization. The following scaling *options* are provided:

NONE	No scaling is applied. This option is the default.
ABSOLUTE	Absolute scaling is applied.
STANDARD	Standard scaling is applied.
<i>User-Defined</i>	Scaling is computed by a user-defined subroutine that is created using the FCMP procedure, where <i>User-Defined</i> is the subroutine name.

Scaling is applied to the working input sequence, which can be a subset of the working input time series if the SLIDE=INDEX or SLIDE=SEASON option is specified.

SDIF=(numlist)

specifies the seasonal differencing to be applied to the accumulated time series. The list of seasonal differencing orders must be separated by spaces or commas. For example, SDIF=(1,3) specifies first, then third, order seasonal differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the SDIF= option. Seasonal differencing is useful when you want to deseasonalize the time series before computing the similarity measures.

SETMISSING=option | number

SETMISS=option | number

specifies how missing values (either actual or accumulated) are interpreted in the accumulated time series or ordered sequence for variables listed in the INPUT statement. If the SETMISSING= option is not specified in the INPUT statement, missing values are set based on the SETMISSING= option in the ID statement. If the SETMISSING= option is not specified in the ID statement or the INPUT statement, no missing value interpretation is performed. See the ID statement SETMISSING= option for more details.

TRANSFORM=option

specifies the time series transformation to be applied to the accumulated time series. The following transformations are provided:

NONE	No transformation is applied. This option is the default.
LOG	Logarithmic transformation is applied.
SQRT	Square-root transformation is applied.
LOGISTIC	Logistic transformation is applied.
BOXCOX(<i>number</i>)	Box-Cox transformation with parameter is applied, where the real <i>number</i> is between -5 and 5.
<i>User-Defined</i>	Transformation is computed by a user-defined subroutine that is created using the FCMP procedure, where <i>User-Defined</i> is the subroutine name.

When the TRANSFORM= option is specified, the time series must be strictly positive unless a user-defined function is used.

TRIMMISSING=option**TRIMMISSING=option**

specifies how missing values (either actual or accumulated) are trimmed from the accumulated time series or ordered sequence for variables that are listed in the INPUT statement. The following trimming options are provided:

NONE	No missing value trimming is applied.
LEFT	Beginning missing values are trimmed.
RIGHT	Ending missing values are trimmed.
BOTH	Both beginning and ending missing value are trimmed. This is the default.

ZEROMISS=option

specifies how beginning and ending zero values (either actual or accumulated) are interpreted in the accumulated time series or ordered sequence for variables listed in the INPUT statement. If the ZEROMISS= option is not specified in the INPUT statement, beginning and ending zero values are set based on the ZEROMISS= option of the ID statement. If the ZERO= option is not specified in the ID statement or the INPUT statement, no zero value interpretation is performed. See the ID statement ZEROMISS= option for more details.

TARGET Statement

TARGET *variable-list* < / *options* > ;

The TARGET statement lists the numeric target variables in the DATA= data set whose values are to be accumulated to form the time series or represent ordered numeric sequences (when no ID statement is specified).

An input data set variable can be specified in only one INPUT or TARGET statement. Any number of TARGET statements can be used. The following *options* can be used with a TARGET statement:

ACCUMULATE=option

specifies how the data set observations are accumulated within each time period for the variables listed in the TARGET statement. If the ACCUMULATE= option is not specified in the TARGET statement, accumulation is determined by the ACCUMULATE= option in the ID statement. If the ACCUMULATE= option is not specified in the ID statement or the TARGET statement, no accumulation is performed. See the ID statement ACCUMULATE= option for more details.

COMPRESS=option | (options)

specifies the sliding sequence (global) and warping (local) compression range of the target sequence with respect to the input sequence. Compression of the target sequence is the same as expansion of the input sequence and vice versa. The compression limits are defined based on the length of the target sequence and are imposed on the target sequence. The following compression options are provided:

GLOBALABS=integer specifies the absolute global compression, where *integer* ranges from zero to 10,000. GLOBALABS=0 implies no global compression, which is the default unless the GLOBALPCT= option is specified.

GLOBALPCT=number specifies global compression as a percentage of the length of the target sequence, where *number* ranges from zero to 100. GLOBALPCT=0 implies no global compression, which is the default. GLOBALPCT=100 implies maximum allowable compression.

LOCALABS=integer specifies the absolute local compression, where *integer* ranges from zero to 10,000. The default is maximum allowable absolute local compression unless the LOCALPCT= option is specified.

LOCALPCT=number specifies local compression as a percentage of the length of the input sequence, where *number* ranges from zero to 100. The percentage specified by the LOCALPCT= option must be less than the GLOBALPCT= option. LOCALPCT=0 implies no local compression. LOCALPCT=100 implies maximum allowable local compression. The default is LOCALPCT=100.

If the SLIDE=NONE or the SLIDE=SEASON option is specified in the TARGET statement, the global compression options are ignored. To disallow local compression, use the option COMPRESS=(LOCALPCT=0 LOCALABS=0).

If the SLIDE=INDEX option is specified, the global compression options are not ignored. To completely disallow both global and local compression, use the option COMPRESS=(GLOBALPCT=0 LOCALPCT=0) or COMPRESS=(GLOBALABS=0 LOCALABS=0). To allow only local compression, use the option COMPRESS=(GLOBALPCT=0 GLOBALABS=0). These are the default compression options.

The preceding options can be used in combination to specify the desired amount of global and local compression as the following examples illustrate, where L_c denotes the global compression limit and l_c denotes the local compression limit:

- COMPRESS=(GLOBALPCT=20) allows the global and local compression to range from zero to $L_c = \min(\lfloor 0.2N_y \rfloor, (N_y - 1))$.
- COMPRESS=(GLOBALPCT=20 GLOBALABS=10) allows the global and local compression to range from zero to $L_c = \min(\lfloor 0.2N_y \rfloor, \min((N_y - 1), 10))$.
- COMPRESS=(LOCALPCT=10) allows the local compression to range from zero to $l_c = \min(\lfloor 0.1N_y \rfloor, (N_y - 1))$.
- COMPRESS=(LOCALPCT=20 LOCALABS=5) allows the local compression to range from zero to $l_c = \min(\lfloor 0.2N_y \rfloor, \min((N_y - 1), 5))$.
- COMPRESS=(GLOBALPCT=20 LOCALPCT=20) allows the global compression to range from zero to $L_c = \min(\lfloor 0.2N_y \rfloor, (N_y - 1))$ and allows the local compression to range from zero to $l_c = \min(\lfloor 0.2N_y \rfloor, (N_y - 1))$.
- COMPRESS=(GLOBALPCT=20 GLOBALABS=10 LOCALPCT=10 LOCALABS=5) allows the global compression to range from zero to $L_c = \min(\lfloor 0.2N_y \rfloor, \min((N_y - 1), 10))$ and allows the local compression to range from zero to $l_c = \min(\lfloor 0.1N_y \rfloor, \min((N_y - 1), 5))$.

Suppose T_z is the length of the input time series and N_y is the length of the target sequence. The *valid* global compression limit, L_c , is always limited by the length of the target sequence: $0 \leq L_c < N_y$.

Suppose N_x is the length of the input sequence and N_y is the length of the target sequence. The *valid* local compression limit, l_c , is always limited by the lengths of the input and target sequence: $\max(0, (N_y - N_x)) \leq l_c < N_y$.

DIF=(numlist)

specifies the differencing to be applied to the accumulated time series. The list of differencing orders must be separated by spaces or commas. For example, DIF=(1,3) specifies first, then third, order differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the DIF= option. Simple differencing is useful when you want to detrend the time series before computing the similarity measures.

EXPAND=option | (options)

specifies the sliding sequence (global) and warping (local) expansion range of the target sequence with respect to the input sequence. Expansion of the target sequence is the same as compression of the input sequence and vice versa. The expansion limits are defined based on the length of the input sequence, but are imposed on the target sequence. The following expansion options are provided:

GLOBALABS=*integer* specifies the absolute global expansion, where *integer* ranges from zero to 10,000. GLOBALABS=0 implies no global expansion, which is the default unless the GLOBALPCT= option is specified.

GLOBALPCT=*number* specifies global expansion as a percentage of the length of the target sequence, where *number* ranges from zero to 100. GLOBALPCT=0 implies no global expansion, which is the default unless the GLOBALABS= option is specified. GLOBALPCT=100 implies maximum allowable global expansion.

LOCALABS=*integer* specifies the absolute local expansion, where *integer* ranges from zero to 10,000. The default is the maximum allowable absolute local expansion unless the LOCALPCT= option is specified.

LOCALPCT=*number* specifies local expansion as a percentage of the length of the target sequence, where *number* ranges from zero to 100. LOCALPCT=0 implies no local expansion. LOCALPCT=100 implies maximum allowable local expansion. The default is LOCALPCT=100.

If the SLIDE=NONE or the SLIDE=SEASON option is specified in the TARGET statement, the global expansion options are ignored. To disallow local expansion, use the option EXPAND=(LOCALPCT=0 LOCALABS=0).

If the SLIDE=INDEX option is specified, the global expansion options are not ignored. To completely disallow both global and local expansion, use the option EXPAND=(GLOBALPCT=0 LOCALPCT=0) or EXPAND=(GLOBALABS=0 LOCALABS=0). To allow only local expansion, use the option EXPAND=(GLOBALPCT=0 GLOBALABS=0). These are the default expansion options.

The preceding options can be used in combination to specify the desired amount of global and local expansion as the following examples illustrate, where L_e denotes the global expansion limit and l_e denotes the local expansion limit:

- EXPAND=(GLOBALPCT=20) allows the global and local expansion to range from zero to $L_e = \min(\lfloor 0.2N_y \rfloor, (N_y - 1))$.
- EXPAND=(GLOBALPCT=20 GLOBALABS=10) allows the global and local expansion to range from zero to $L_e = \min(\lfloor 0.2N_y \rfloor, \min((N_y - 1), 10))$.
- EXPAND=(LOCALPCT=10) allows the local expansion to range from zero to $l_e = \min(\lfloor 0.1N_y \rfloor, (N_y - 1))$.
- EXPAND=(LOCALPCT=10 LOCALABS=5) allows the local expansion to range from zero to $l_e = \min(\lfloor 0.1N_y \rfloor, \min((N_y - 1), 5))$.
- EXPAND=(GLOBALPCT=20 LOCALPCT=10) allows the global expansion to range from zero to $L_e = \min(\lfloor 0.2N_y \rfloor, (N_y - 1))$ and allows the local expansion to range from zero to $l_e = \min(\lfloor 0.1N_y \rfloor, (N_y - 1))$.
- EXPAND=(GLOBALPCT=20 GLOBALABS=10 LOCALPCT=10 LOCALABS=5) allows the global expansion to range from zero to $L_e = \min(\lfloor 0.2N_y \rfloor, \min((N_y - 1), 10))$ and allows the local expansion to range from zero to $l_e = \min(\lfloor 0.1N_y \rfloor, \min((N_y - 1), 5))$.

Suppose T_z is the length of the input time series and N_y is the length of the target sequence. The *valid* global expansion limit, L_e , is always limited by the length of the input time series: $0 \leq L_e < T_z$.

Suppose N_x is the length of the input sequence and N_y is the length of the target sequence. The *valid* local expansion limit, l_e , is always limited by the lengths of the input and target sequence: $\max(0, (N_x - N_y)) \leq l_e < N_x$.

MEASURE=*option*

specifies the similarity measure to be computed by using the working input and target sequences. The following similarity measures are provided:

SQRDEV	squared deviation. This option is the default.
ABSDEV	absolute deviation
MSQRDEV	mean squared deviation
MSQRDEVINP	mean squared deviation relative to the length of the input sequence
MSQRDEVTAR	mean squared deviation relative to the length of the target sequence
MSQRDEVMIN	mean squared deviation relative to the minimum valid path length
MSQRDEVMAX	mean squared deviation relative to the maximum valid path length
MABSDEV	mean absolute deviation
MABSDEVINP	mean absolute deviation relative to the length of the input sequence
MABSDEVTAR	mean absolute deviation relative to the length of the target sequence
MABSDEVMIN	mean absolute deviation relative to the minimum valid path length
MABSDEVMAX	mean absolute deviation relative to the maximum valid path length
<i>User-Defined</i>	The measure is computed by a user-defined function created by using the FCMP procedure, where <i>User-Defined</i> is the function name.

NORMALIZE=option

specifies the sequence normalization to be applied to the working target sequence. The following normalization options are provided:

NONE	No normalization is applied. This option is the default.
ABSOLUTE	Absolute normalization is applied.
STANDARD	Standard normalization is applied.
<i>User-Defined</i>	Normalization is computed by a user-defined subroutine that is created by using the FCMP procedure, where <i>User-Defined</i> is the subroutine name.

PATH=option

specifies the similarity measure and warping path information to be computed using the working input and target sequences. The following similarity measures and warping path are provided:

<i>User-Defined</i>	The measure and path are computed by a user-defined subroutine that is created by using the FCMP procedure, where <i>User-Defined</i> is the subroutine name
---------------------	--

For computational efficiency, the PATH= option should be only used when you want to compute both the similarity measure and the warping path information. If only the similarity measure is needed, use the MEASURE= option. If you specify both the MEASURE= and PATH= option in the TARGET statement, the PATH= option takes precedence.

SDIF=(numlist)

specifies the seasonal differencing to be applied to the accumulated time series. The list of seasonal differencing orders must be separated by spaces or commas. For example, SDIF=(1,3)

specifies first, then third, order seasonal differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the SDIF= option. Seasonal differencing is useful when you want to deseasonalize the time series before computing the similarity measures.

SETMISSING=*option* | *number*

SETMISS=*option* | *number*

option specifies how missing values (either actual or accumulated) are interpreted in the accumulated time series for variables that are listed in the TARGET statement. If the SETMISSING= option is not specified in the TARGET statement, missing values are set based on the SETMISSING= option in the ID statement. If the SETMISSING= option is not specified in the ID statement or the TARGET statement, no missing value interpretation is performed. See the ID statement SETMISSING= option for more details.

SLIDE=*option*

specifies the sliding of the target sequence with respect to the input sequence. The following slides are provided:

NONE	No sequence sliding. The input time series is compared with the target sequence directly with no sliding. This option is the default.
INDEX	Slide by time index. The input time series is compared with the target sequence by observation index.
SEASON	Slide by seasonal index. The input time series is compared with the target sequence by seasonal index.

The SLIDE= option takes precedence over the COMPRESS= and EXPAND= options.

TRANSFORM=*option*

specifies the time series transformation to be applied to the accumulated time series. The following transformations are provided:

NONE	No transformation is applied. This option is the default.
LOG	Logarithmic transformation is applied.
SQRT	Square-root transformation is applied.
LOGISTIC	Logistic transformation is applied.
BOXCOX(<i>number</i>)	Box-Cox transformation with parameter <i>number</i> is applied, where the real <i>number</i> is between -5 and 5
<i>User-Defined</i>	Transformation is computed by a user-defined subroutine that is created by using the FCMP procedure, where <i>User-Defined</i> is the subroutine name.

When the TRANSFORM= option is specified, the time series must be strictly positive unless a user-defined function is used.

TRIMMISSING=option**TRIMMISS= option**

specifies how missing values (either actual or accumulated) are trimmed from the accumulated time series or ordered sequence for variables that are listed in the TARGET statement. The following trimming options are provided:

NONE	No missing value trimming is applied.
LEFT	Beginning missing values are trimmed.
RIGHT	Ending missing values are trimmed.
BOTH	Both beginning and ending missing values are trimmed. This is the default.

ZEROMISS=option

specifies how beginning and ending zero values (either actual or accumulated) are interpreted in the accumulated time series or ordered sequence for variables listed in the TARGET statement. If the ZEROMISS= option is not specified in the TARGET statement, beginning and ending values are set based on the ZEROMISS= option in the ID statement. See the ID statement ZEROMISS= option for more details.

Details: SIMILARITY Procedure

You can use the SIMILARITY procedure to do the following functions, which are done in the order shown. First, you can form time series data from transactional data with the options shown:

1. accumulation ACCUMULATE= option
2. missing value interpretation SETMISSING= option
3. zero value interpretation ZEROMISS= option

Next, you can transform the accumulated time series to form the working time series with the following options. Transformations are useful when you want to stabilize the time series before computing the similarity measures. Simple and seasonal differencing are useful when you want to detrend or deseasonalize the time series before computing the similarity measures. Often, but not always, the TRANSFORM=, DIF=, and SDIF= options should be specified in the same way for both the target and input variables.

4. time series transformation TRANSFORM= option
5. time series differencing DIF= and SDIF= option
6. time series missing value trimming TRIMMISSING= option
7. time series descriptive statistics PRINT=DESCSTATS option

After the working series is formed, you can treat it as an ordered sequence that can be normalized or scaled. Normalizations are useful when you want to compare the “shape” or “profile” of the time series. Scaling is useful when you want to compare the input sequence to the target sequence while discounting the variation of the target sequence.

- | | |
|------------------|-------------------|
| 8. normalization | NORMALIZE= option |
| 9. scaling | SCALE= option |

After the working sequences are formed, you can compute similarity measures between input and target sequences:

- | | |
|------------------------|------------------------------|
| 10. sliding | SLIDE= option |
| 11. warping | COMPRESS= and EXPAND= option |
| 12. similarity measure | MEASURE= and PATH= option |

The SLIDE= option specifies observation-index sliding, seasonal-index sliding, or no sliding. The COMPRESS= and EXPAND= options specify the warping limits. The MEASURE= and PATH= options specify how the similarity measures are computed.

Accumulation

If the ACCUMULATE= option is specified in the ID, INPUT, or TARGET statement, data set observations are accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option in the ID statement. The ID variable contains the time ID values. Each time ID value corresponds to a specific time period. Accumulation is particularly useful when the input data set contains transactional data, whose observations are not spaced with respect to any particular time interval. The accumulated values form the time series, which is used in subsequent analyses.

For example, suppose a data set contains the following observations:

19MAR1999	10
19MAR1999	30
11MAY1999	50
12MAY1999	20
23MAY1999	20

If the INTERVAL=MONTH is specified, all of the preceding observations fall within three time periods of March 1999, April 1999, and May 1999. The observations are accumulated within each time period as follows:

If the ACCUMULATE=NONE option is specified, an error is generated because the ID variable values are not equally spaced with respect to the specified frequency (MONTH).

If the ACCUMULATE=TOTAL option is specified, the data are accumulated as follows:

```
O1MAR1999    40
O1APR1999    .
O1MAY1999    90
```

If the ACCUMULATE=AVERAGE option is specified, the data are accumulated as follows:

```
O1MAR1999    20
O1APR1999    .
O1MAY1999    30
```

If the ACCUMULATE=MINIMUM option is specified, the data are accumulated as follows:

```
O1MAR1999    10
O1APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=MEDIAN option is specified, the data are accumulated as follows:

```
O1MAR1999    20
O1APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=MAXIMUM option is specified, the data are accumulated as follows:

```
O1MAR1999    30
O1APR1999    .
O1MAY1999    50
```

If the ACCUMULATE=FIRST option is specified, the data are accumulated as follows:

```
O1MAR1999    10
O1APR1999    .
O1MAY1999    50
```

If the ACCUMULATE=LAST option is specified, the data are accumulated as follows:

```
O1MAR1999    30
O1APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=STDDEV option is specified, the data are accumulated as follows:

```

O1MAR1999    14.14
O1APR1999    .
O1MAY1999    17.32

```

As can be seen from the preceding examples, even though the data set observations contain no missing values, the accumulated time series can have missing values.

Missing Value Interpretation

Sometimes missing values should be interpreted as unknown values. But sometimes missing values are known, such as when missing values are created from accumulation and no observations should be interpreted as no (zero) value. In the former case, the SETMISSING= option in the ID, INPUT, or TARGET statement can be used to interpret how missing values are treated. The SETMISSING=0 option should be used when missing observations are to be treated as no (zero) values. In other cases, missing values should be interpreted as global values, such as minimum or maximum values of the accumulated series. The accumulated and interpreted time series is used in subsequent analyses.

The SETMISSING=0 option should be used with missing observations are to be treated as a zero value. In other cases, missing values should be interpreted as global values, such as minimum or maximum values of the accumulated series. The accumulated and interpreted time series is then used in subsequent analyses.

Zero Value Interpretation

When querying certain databases for time-stamped data based on a particular time range, time periods that contain no data are sometimes assigned zero values. For certain analyses, it is more desirable to assign these values to missing. Often, these beginning or ending zero values need to be interpreted as missing values. The ZEROMISS= option in the ID, INPUT, or TARGET statement specifies that the beginning, ending, or both the beginning and ending values are to be interpreted as zero values.

Time Series Transformation

Transformations are useful when you want to stabilize the time series before computing the similarity measures. There are four transformations available, for strictly positive series only. Let $y_t > 0$ be the original time series, and let w_t be the transformed series. The transformations are defined as follows:

Log is the logarithmic transformation,

$$w_t = \ln(y_t)$$

Logistic is the logistic transformation,

$$w_t = \ln(cy_t/(1 - cy_t))$$

where the scaling factor c is

$$c = (1 - e^{-6})10^{-\text{ceil}(\log_{10}(\max(y_t)))}$$

and $\text{ceil}(x)$ is the smallest integer greater than or equal to x .

Square root is the square root transformation,

$$w_t = \sqrt{y_t}$$

Box-Cox is the Box-Cox transformation,

$$w_t = \begin{cases} \frac{y_t^\lambda - 1}{\lambda} & \lambda \neq 0 \\ \ln(y_t) & \lambda = 0 \end{cases}$$

User-Defined is the transformation computed by a user-defined subroutine that is created by using the FCMP procedure, where *User-Defined* is the subroutine name.

Other time series transformations can be performed prior to invoking the SIMILARITY procedure by using the SAS/ETS EXPAND procedure or the DATA step.

Time Series Differencing

After optionally transforming the series, the accumulated series can be simply or seasonally differenced using the INPUT or TARGET statement DIF= and SDIF= options. Simple and seasonal differencing are useful when you want to detrend or deseasonalize the time series before computing the similarity measures.

For example, suppose y_t is a monthly time series. The following examples of the DIF= and SDIF= options demonstrate how to simply and seasonally difference the time series: DIF=(1,3) specifies first, then third, order differencing; SDIF=(1,3) specifies first, then third, order seasonal differencing.

Additionally, assuming that y_t is strictly positive, the INPUT or TARGET statement TRANSFORM= option and the DIF= and SDIF= options can be combined.

Time Series Missing Value Trimming

In some instances, missing values should be interpreted as an unknown observation, but other times, missing values are known and should be interpreted as a zero value. This is the case when missing values are created from accumulation, and a missing observation should be interpreted as having no value (meaning a value of zero). In the former case, the SETMISSING=option in the ID, INPUT, or TARGET, statement can be used to interpret how missing observations should be treated. By default, missing values, at the beginning and ending of the data set, are trimmed from the data set prior to analysis. This can be performed using TRIMMISS=both.

Time Series Descriptive Statistics

After a series has been optionally accumulated and transformed with missing values interpreted, descriptive statistics can be computed for the resulting working series by specifying the PRINT=DESCSTATS option. This option produces an ODS table that contains the sum, mean, minimum, maximum, and standard deviation of the working series.

Input and Target Sequences

After the input and target working series are formed, they can be treated as two ordered sequences. Given an input time sequence, x_i , for $i = 1$ to N_x , where i is the input sequence index, and a target time sequence, y_j , for $j = 1$ to N_y , where j is the target sequence index, these sequences are analyzed for similarity.

Sliding Sequences

Similarity measures can be computed between the target sequence and any contiguous subsequences of the input time series.

There are three types of sequence sliding:

- no sliding
- slide by time index
- slide by season index

For more information, see Leonard, Elsheimer, and Sloan (2008).

Time Warping

Time warping allows for the comparison between target and input sequences of differing lengths by compressing or expanding the input sequence with respect to the target sequence while respecting the order of the sequence elements.

For more information, see Leonard, Elsheimer, and Sloan (2008).

Sequence Normalization

The working (input or target) sequence can be normalized prior to further analysis. Let q_i be the original sequence with mean μ_q and standard deviation σ_q , and let r_t be the normalized sequence. The normalizations are defined as follows:

- Standard is the standard normalization

$$r_i = (q_i - \mu_q) / \sigma_q$$

- Absolute is the absolute normalization

$$r_i = (q_i - \min(q_i)) / (\max(q_i) - \min(q_i))$$

- User-defined is a user-defined normalization created by the FCMP procedure.

Sequence Scaling

The working input sequence can be scaled to the working target sequence. Sequence scaling is applied after normalization. Let y_j be the working target sequence with mean μ_y and standard deviation σ_y . Let x_i be the working input sequence and let q_i be the scaled sequence. The scaling is defined as follows:

- Standard is the standard normalization

$$q_i = (x_i - \mu_y) / \sigma_y$$

- Absolute is the absolute scaling

$$q_i = (x_i - \min(y_j)) / (\max(y_j) - \min(y_j))$$

- User-defined is a user-defined scaling created by the FCMP procedure.

Similarity Measures

The working input sequence can be compared to the working target sequence to create a similarity. For more information, see Leonard, Elsheimer, and Sloan (2008).

User-Defined Functions and Subroutines

A user-defined routine can be written in the SAS language by using the FCMP procedure or in the C language by using both the FCMP procedure and the PROTO procedure, respectively. The SIMILARITY procedure cannot use C language routines directly. The procedure can use only SAS language routines that might or might not call C language routines. Creating user-defined routines is more completely described in the FCMP procedure and the PROTO procedure documentation. The FCMP and PROTO procedures are part of Base SAS software.

The SAS language provides integrated memory management and exception handling such as operations on missing values. The C language provides flexibility and allows the integration of existing C language libraries. However, proper memory management and exception handling are solely the responsibility of the user. Additionally, the support for standard C libraries is restricted. If you have a choice, it is highly recommended that you write user-defined functions and subroutines in the SAS language using the FCMP procedure.

For each of the tasks previously described, the following sections describe the required subroutine or function signature and provide examples of using a user-defined routine with the SIMILARITY procedure.

Time Series Transformations

A user-defined transformation subroutine has the following subroutine signature:

```
SUBROUTINE <SUBROUTINE-NAME> ( <ARRAY-NAME>[*] );
```

where the array-name is the time series to be transformed.

For example, to duplicate the functionality of the built-in TRANSFORM=LOG option in the INPUT and TARGET statement, the following SAS statements create a user-defined version of this transformation called MYTRANSFORM and store this subroutine in the catalog SASUSER.MYSIMILAR.

```
proc fcmp outlib=sasuser.mysimilar.package;

  subroutine mytransform( series[*] );

    outargs series;

    length = DIM(series);

    do i = 1 to length;
      value = series[i];
      if value > 0 then do;
        series[i] = log( value );
      end;
      else do;
        series[i] = .;
      end;
    end;
  endsubr;
endproc;
```

```

        end;
    end;

endsub;

run;

```

This user-defined subroutine can be specified in the TRANSFORM= option in the INPUT or TARGET statement as follows:

```

options cmlib = sasuser.mysimilar;

proc similarity ...;
...
input myinput / transform=mytransform;
target mytarget / transform=mytransform;
...
run;

```

Sequence Normalizations

A user-defined normalization subroutine has the following signature:

```

SUBROUTINE <SUBROUTINE-NAME> ( <ARRAY-NAME>[*] );

```

where the array-name is the sequence to be normalized.

For example, to duplicate the functionality of the built-in NORMALIZE=ABSOLUTE option in the INPUT and TARGET statement, the following SAS statements create a user-defined version of this normalization called MYNORMALIZE and store this subroutine in the catalog SASUSER.MYSIMILAR.

```

proc fcmp outlib=sasuser.mysimilar.package;

subroutine mynormalize( sequence[*] );

    outargs sequence;

    length = DIM(sequence);
    minimum = .; maximum = .;

    do i = 1 to length;
        value = sequence[i];
        if nmiss(minimum) | nmiss(maximum) then do;
            minimum = value;
            maximum = value;
        end;
        if nmiss(value) = 0 then do;
            if value < minimum then minimum = value;
            if value > maximum then maximum = value;
        end;
    end;
end;

```

```

        end;
    end;

    do i = 1 to length;
        value = sequence[i];
        if nmiss( value ) | minimum > maximum then do;
            sequence[i] = .;
        end;
        else do;
            sequence[i] = (value - minimum) / (maximum - minimum);
        end;
    end;

endsub;

run;

```

This user-defined subroutine can be specified in the NORMALIZE= option in the INPUT or TARGET statement as follows:

```

options cmlib = sasuser.mysimilar;

proc similarity ...;
    ...
    input myinput / normalize=mynormalize;
    target mytarget / normalize=mynormalize;
    ...
run;

```

Sequence Scaling

A user-defined scaling subroutine has the following signature:

```

SUBROUTINE <SUBROUTINE-NAME> ( <ARRAY-NAME>[*], <ARRAY-NAME>[*] );

```

where the first array-name is the target sequence and the second array-name is the input sequence to be scaled.

For example, to duplicate the functionality of the built-in SCALE=ABSOLUTE option in the INPUT statement, the following SAS statements create a user-defined version of this scaling called MYSCALE and store this subroutine in the catalog SASUSER.MYSIMILAR.

```

proc fcmp outlib=sasuser.mysimilar.package;

    subroutine myscale( target[*], input[*] );

        outargs input;

        length = DIM(target);

```

```

minimum = .; maximum = .;

do i = 1 to length;
  value = target[i];
  if nmiss(minimum) | nmiss(maximum) then do;
    minimum = value;
    maximum = value;
  end;
  if nmiss(value) = 0 then do;
    if value < minimum then minimum = value;
    if value > maximum then maximum = value;
  end;
end;

do i = 1 to length;
  value = input[i];
  if nmiss( value ) | minimum > maximum then do;
    input[i] = .;
  end;
  else do;
    input[i] = (value - minimum) / (maximum - minimum);
  end;
end;

endsub;

run;

```

This user-defined subroutine can be specified in the SCALE= option in the INPUT statement as follows:

```

options cmlib=sasuser.mysimilar;

proc similarity ...;
  ...
  input myinput / scale=myscale;
  ...
run;

```

Similarity Measures

A user-defined similarity measure function has the following signature:

```

FUNCTION <FUNCTION-NAME> ( <ARRAY-NAME>[*], <ARRAY-NAME>[*] );

```

where the first array-name is the target sequence and the second array-name is the input sequence. The return value of the function is the similarity measure associated with the target sequence and the input sequence.

For example, to duplicate the functionality of the built-in MEASURE=ABSDEV option in the TARGET statement with no warping, the following SAS statements create a user-defined version of this measure called MYMEASURE and store this subroutine in the catalog SASUSER.MYSIMILAR.

```
proc fcmp outlib=sasuser.mysimilar.package;

  function mymeasure( target[*], input[*] );

    length = min(DIM(target), DIM(input));
    sum = 0; num = 0;

    do i = 1 to length;
      x = input[i];
      w = target[i];
      if nmiss(x) = 0 & nmiss(w) = 0 then do;
        d = x - w;
        sum = sum + abs(d);
      end;
    end;

    if num <= 0 then return(.);

    return(sum);

  endsub;

run;
```

This user-defined function can be specified in the MEASURE= option in the TARGET statement as follows:

```
options cmlib=sasuser.mysimilar;

proc similarity ...;
  ...
  target mytarget / measure=mymeasure;
  ...
run;
```

For another example, to duplicate the functionality of the built-in MEASURE=SQRDEV and MEASURE=ABSDEV options by using the C language, the following SAS statements create a user-defined C language version of these measures called DTW_SQRDEV_C and DTW_ABSDEV_C and store these functions in the catalog SASUSER.CSIMIL.CFUNCS. DTW refers to dynamic time warping. These C language functions can be then called by SAS language functions and subroutines.

```
proc proto package=sasuser.csimil.cfuncs;

  mapmiss double = 999999999;

  double dtw_sqrdev_c( double * target / iotype=input,
```

```

        int      targetLength,
        double * input / iotype=input,
        int      inputLength );

externc dtw_sqrdev_c;
double dtw_sqrdev_c( double * target,
                    int      targetLength,
                    double * input,
                    int      inputLength )
{
    int      i, j;
    double   x, w, d;
    double * prev = (double *)malloc( sizeof(double)*targetLength);
    double * curr = (double *)malloc( sizeof(double)*inputLength);
    if ( prev == 0 || curr == 0 ) return 999999999;

    x = input[0];
    for ( j=0; j<targetLength; j++ ) {
        w = target[j];
        d = x - w;
        d = d*d;
        if ( j == 0 ) prev[j] = d;
        else          prev[j] = d + prev[j-1];
    }

    for (i=1; i<inputLength; i++ ) {
        x = input[i];

        j = 0;
        w = target[j];
        d = x - w;
        d = d*d;
        curr[j] = d + prev[j];

        for (j=1; j<targetLength; j++ ) {
            w = target[j];
            d = x - w;
            d = d*d;
            curr[j] = d + fmin( prev[j],
                               fmin( prev[j-1], curr[j]));
        }

        if ( i < targetLength ) {
            for( j=0; j<inputLength; j++ )
                prev[j] = curr[j];
        }
    }

    d = curr[inputLength-1];
    free( (char*) prev);
    free( (char*) curr);
    return( d );
}
externcend;

```

```

double dtw_absdev_c( double * target / iotype=input,
                    int      targetLength,
                    double * input / iotype=input,
                    int      inputLength );
externc dtw_absdev_c;
double dtw_absdev_c( double * target,
                    int      targetLength,
                    double * input,
                    int      inputLength )
{
    int      i,j;
    double   x,w,d;
    double * prev = (double *)malloc( sizeof(double)*targetLength);
    double * curr = (double *)malloc( sizeof(double)*inputLength);
    if ( prev == 0 || curr == 0 ) return 999999999;

    x = input[0];
    for ( j=0; j<targetLength; j++ ) {
        w = target[j];
        d = x - w;
        d = fabs(d);
        if ( j == 0 ) prev[j] = d;
        else prev[j] = d + prev[j-1];
    }

    for ( i=1; i<inputLength; i++ ) {
        x = input[i];

        j = 0;
        w = target[j];
        d = x - w;
        d = fabs(d);
        curr[j] = d + prev[j];

        for ( j=1; j<targetLength; j++ ) {
            w = target[j];
            d = x - w;
            d = fabs(d);
            curr[j] = d + fmin( prev[j],
                               fmin( prev[j-1], curr[j] ));
        }

        if ( i < inputLength ) {
            for ( j=0; j<targetLength; j++ )
                prev[j] = curr[j];
        }
    }

    d = curr[inputLength-1];
    free( (char*) prev);
    free( (char*) curr);
    return( d );
}

```

```

    }
externcend;

run;

```

The preceding SAS statements create two C language functions which can then be used in SAS language functions or subroutines or both. However, these functions cannot be directly used by the SIMILARITY procedure. In order to use these C language functions in the SIMILARITY procedure, two SAS language functions must be created that call these two C language functions. The following SAS statements create two user-defined SAS language versions of these measures called DTW_SQRDEV and DTW_ABSDEV and stores these functions in the catalog SASUSER.MYSIMILAR.FUNCS. These SAS language functions use the previously created C language function; the SAS language functions can then be used by the SIMILARITY procedure.

```

proc fcmp outlib=sasuser.mysimilar.funcs
    inlib=sasuser.cfuncs;

    function dtw_sqrdev( target[*], input[*] );
        dev = dtw_sqrdev_c(target,DIM(target),input,DIM(input));
        return( dev );
    endsub;

    function dtw_absdev( target[*], input[*] );
        dev = dtw_absdev_c(target,DIM(target),input,DIM(input));
        return( dev );
    endsub;

run;

```

This user-defined function can be specified in the MEASURE= option in the TARGET statement as follows:

```

options cmplib=sasuser.mysimilar;

proc similarity ...;
    ...
    target mytarget / measure=dtw_sqrdev;
    target yourtarget / measure=dtw_absdev;
    ...
run;

```

Similarity Measures and Warping Path

A user-defined similarity measure and warping path information function has the following signature:

```

FUNCTION <FUNCTION-NAME> ( <ARRAY-NAME>[*], <ARRAY-NAME>[*],
    <ARRAY-NAME>[*], <ARRAY-NAME>[*],
    <ARRAY-NAME>[*] );

```

where the first array-name is the target sequence, the second array-name is the input sequence, the third array-name is the returned target sequence indices, the fourth array-name is the returned input sequence indices, the fifth array-name is the returned path distances. The returned value of the function is the similarity measure. The last three returned arrays are used to compute the path and cost statistics.

The returned sequence indices must represent a valid warping path; that is, integers greater than zero and less than or equal to the sequence length and recorded in ascending order. The returned path distances must be nonnegative numbers.

Output Data Sets

The SIMILARITY procedure can create the OUT=, OUTMEASURE=, OUTPATH=, OUTSEQUENCE=, and OUTSUM= data sets. In general, these data sets contain the variables listed in the BY statement. The ID statement time ID variable is also included in the data sets when the time dimension is important. If an analysis step related to an output data step fails, then the values of this step are not recorded or are set to missing in the related output data set, and appropriate error and warning messages are recorded in the SAS log.

OUT= Data Set

The OUT= data set contains the variables that are specified in the BY, ID, INPUT, and TARGET statements. If the ID statement is specified, the ID variable values are aligned and extended based on the ALIGN=, INTERVAL=, START=, and END= options. The values of the variables specified in the INPUT and TARGET statements are accumulated based on the ACCUMULATE= option, missing values are interpreted based on the SETMISSING= option, and zero values are interpreted using the ZEROMISS= option. The accumulated time series is transformed based on the TRANSFORM=, DIF=, and SDIF= options.

OUTMEASURE= Data Set

The OUTMEASURE= data set records the similarity measures between each INPUT and TARGET statement variable with respect to each time ID value. The form of the OUTMEASURE= data set depends on the SORTNAMES and ORDER= options. The OUTMEASURE= data set contains the variables specified in the BY statement in addition to the variables listed below.

For ORDER=INPUTTARGET and ORDER=TARGETINPUT, the OUTMEASURE= data set has the following form:

<code>_INPUT_</code>	input variable name
<code>_TARGET_</code>	target variable name

<code>_TIMEID_</code>	time ID values
<code>_INPSEQ_</code>	input sequence values
<code>_TARSEQ_</code>	target sequence values
<code>_SIM_</code>	similarity measures

The `OUTMEASURE=` data set is ordered by the variables `_INPUT_`, then `_TARGET_`, then `_TIMEID_` when `ORDER=INPUTTARGET`. The `OUTMEASURE=` data set is ordered by the variables `_TARGET_`, then `_INPUT_`, then `_TIMEID_` when `ORDER=TARGETINPUT`.

For `ORDER=INPUT`, the `OUTMEASURE=` data set has the following form:

<code>_INPUT_</code>	input variable name
<code>_TIMEID_</code>	time ID values
<code>_INPSEQ_</code>	input sequence values
<i>target-names</i>	similarity measures that are associated with each <code>TARGET</code> statement variable name

The `OUTMEASURE=` data set is ordered by the variables `_INPUT_`, then `_TIMEID_`.

For `ORDER=TARGET`, the `OUTMEASURE=` data set has the following form:

<code>_TARGET_</code>	target variable name
<code>_TIMEID_</code>	time ID values
<code>_TARSEQ_</code>	target sequence values
<i>input-names</i>	similarity measures that are associated with each <code>INPUT</code> statement variable name

The `OUTMEASURE=` data set is ordered by the variables `_TARGET_`, then `_TIMEID_`.

OUTPATH= Data Set

The `OUTPATH=` data set records the path analysis between each `INPUT` and `TARGET` statement variable. This data set records the path sequences for each slide index and for each warp index associated with the slide index. The sequence values recorded are normalized and scaled based on the `NORMALIZE=` and `SCALE=` options.

The `OUTPATH=` data set contains the variables specified in the `BY` statement and the following variables:

<code>_INPUT_</code>	input variable name
<code>_TARGET_</code>	target variable name
<code>_TIMEID_</code>	time ID values
<code>_SLIDE_</code>	slide index

<code>_WARP_</code>	warp index
<code>_INPSEQ_</code>	input sequence values
<code>_TARSEQ_</code>	target sequence values
<code>_INPPTH_</code>	input path index
<code>_TARPTH_</code>	target path index
<code>_METRIC_</code>	distance metric values

The sorting of the `OUTPATH=` data set depends on the `SORTNAMES` and the `ORDER=` option.

The `OUTPATH=` data set is ordered by the variables `_INPUT_`, then `_TARGET_`, then `_TIMEID_` when `ORDER=INPUTTARGET` or `ORDER=INPUT`. The `OUTPATH=` data set is ordered by the variables `_TARGET_`, then `_INPUT_`, then `_TIMEID_` when `ORDER=TARGETINPUT` or `ORDER=TARGET`.

If there are a large number of slides or warps or both, this data set might be large.

OUTSEQUENCE= Data Set

The `OUTSEQUENCE=` data set records the input and target sequences that are associated with each `INPUT` and `TARGET` statement variable. This data set records the input and target sequence values for each slide index and for each warp index that is associated with the slide index. The sequence values that are recorded are normalized and scaled based on the `NORMALIZE=` and `SCALE=` options. This data set also contains the similarity measure associated with the two sequences.

The `OUTSEQUENCE=` data set contains the variables specified in the `BY` statement in addition to the following variables:

<code>_INPUT_</code>	input variable name
<code>_TARGET_</code>	target variable name
<code>_TIMEID_</code>	time ID values
<code>_SLIDE_</code>	slide index
<code>_WARP_</code>	warp index
<code>_INPSEQ_</code>	input sequence values
<code>_TARSEQ_</code>	target sequence values
<code>_SIM_</code>	similarity measure
<code>_STATUS_</code>	sequence status

The sorting of the `OUTSEQUENCE=` data set depends on the `SORTNAMES` and the `ORDER=` option.

The `OUTSEQUENCE=` data set is ordered by the variables `_INPUT_`, then `_TARGET_`, then `_TIMEID_` when `ORDER=INPUTTARGET` or `ORDER=INPUT`. The `OUTSEQUENCE=`

data set is ordered by the variables `_TARGET_`, then `_INPUT_`, then `_TIMEID_` when `ORDER=TARGETINPUT` or `ORDER=TARGET`.

If there are a large number of slides or warps or both, this data set might be large.

OUTSUM= Data Set

The `OUTSUM=` data set summarizes the similarity measures between each `INPUT` and `TARGET` statement variable. The form of the `OUTSUM=` data set depends on the `SORTNAMES` and `ORDER=` option. If the `SORTNAMES` option is specified, each variable (`INPUT` or `TARGET`) is analyzed in ascending order. The `OUTSUM=` data set contains the variables specified in the `BY` statement in addition to the variables listed below.

For `ORDER=INPUTTARGET` and `ORDER=TARGETINPUT`, the `OUTSUM=` data set has the following form:

<code>_INPUT_</code>	input variable name
<code>_TARGET_</code>	target variable name
<code>_STATUS_</code>	status flag that indicates whether the requested analyses were successful
<code>_TIMEID_</code>	time ID values
<code>_SIM_</code>	similarity measure summary

The `OUTSUM=` data set is ordered by the variables `_INPUT_`, then `_TARGET_` when `ORDER=INPUTTARGET`. The `OUTSUM=` data set is ordered by the variables `_TARGET_`, then `_INPUT_` when `ORDER=TARGETINPUT`.

For `ORDER=INPUT`, the `OUTSUM=` data set has the following form:

<code>_INPUT_</code>	input variable name
<code>_STATUS_</code>	status flag that indicates whether the requested analyses were successful
<i>target-names</i>	similarity measure summary that is associated with each <code>TARGET</code> statement variable name

The `OUTSUM=` data set is ordered by the variable `_INPUT_`.

For `ORDER=TARGET`, the `OUTSUM=` data set has the following form:

<code>_TARGET_</code>	target variable name
<code>_STATUS_</code>	status flag that indicates whether the requested analyses were successful
<i>input-names</i>	similarity measure summary that is associated with each <code>INPUT</code> statement variable name

The `OUTSUM=` data set is ordered by the variable `_TARGET_`.

STATUS Variable Values

The `_STATUS_` variable contains a code that specifies whether the similarity analysis has been successful or not. The `_STATUS_` variable can take the following values:

0	Success
3000	Accumulation failure
4000	Missing value interpretation failure
6000	Series is all missing
7000	Transformation failure
8000	Differencing failure
9000	Unable to compute descriptive statistics
10000	Normalization failure
11000	Input contains imbedded missing values
12000	Target contains imbedded missing values
13000	Scaling failure
14000	Measure failure
15000	Path failure
16000	Slide summarization failure

Printed Output

The `SIMILARITY` procedure optionally produces printed output by using the Output Delivery System (ODS). By default, the procedure produces no printed output. All output is controlled by the `PRINT=` and `PRINTDETAILS` options in the `PROC SIMILARITY` statement.

The sort, order, and form of the printed output depends on both the `SORTNAMES` option and the `ORDER=` option. If the `SORTNAMES` option is specified, each variable (`INPUT` or `TARGET`) is analyzed in ascending order. For `ORDER=INPUTTARGET`, the printed output is ordered by the `INPUT` statement variables (row) and then by the `TARGET` statement variables (row). For `ORDER=TARGETINPUT`, the printed output is ordered by the `TARGET` statement variables (row) and then by the `INPUT` statement variables (row). For `ORDER=INPUT`, the printed output is ordered by the `INPUT` statement variables (row) and then by the `TARGET` statement variables (column). For `ORDER=TARGET`, the printed output is ordered by the `TARGET` statement variables (row) and then by the `INPUT` statement variables (column).

In general, if an analysis step related to printed output fails, the values of that step are not printed and appropriate error and warning messages are recorded in the SAS log. The printed output is similar to the output data set; these similarities are described as follows:

PRINT=COSTS

prints the costs statistics.

PRINT=DESCSTATS

prints the descriptive statistics.

PRINT=PATHS

prints the path statistics.

PRINT=SLIDES

prints the sliding sequence summary.

PRINT=SUMMARY

prints the summary of similarity measures similar to the OUTSUM= data set.

PRINT=WARPS

prints the warp summary.

PRINTDETAILS

prints each table with greater detail.

ODS Table Names

The following table relates the PRINT= options to ODS tables.

Table 23.2 ODS Tables Produced in PROC SIMILARITY

ODS Table Name	Description	Option
CostStatistics	Cost statistics	PRINT=COSTS
DescStats	Descriptive statistics	PRINT=DESCSTATS
PathLimits	Path limits	PRINT=PATHS
PathStatistics	Path statistics	PRINT=PATHS
SlideMeasuresSummary	Summary of measure per slide	PRINT=SLIDES

Table 23.2 (continued)

ODS Table Name	Description	Option
MeasuresSummary	Measures summary	PRINT=SUMMARY
InputMeasuresSummary	Measures summary	PRINT=SUMMARY
TargetMeasuresSummary	Measures summary	PRINT=SUMMARY
WarpMeasuresSummary	Summary of measure per warp	PRINT=WARPS

The tables are related to a single series within a BY group.

ODS Graphics

This section describes the use of ODS for creating graphics with the SIMILARITY procedure.

To request these graphs, you must specify the ODS GRAPHICS ON statement and you must specify the PLOTS= option in the PROC SIMILARITY statement as described in [Table 23.3](#).

ODS Graph Names

PROC SIMILARITY assigns a name to each graph it creates by using ODS. You can use these names to selectively reference the graphs. The names are listed in [Table 23.3](#).

Table 23.3 ODS Graphics Produced by PROC SIMILARITY

ODS Graph Name	Plot Description	Statement	PLOTS= Option
CostsPlot	Costs plot	SIMILARITY	PLOTS=COSTS
PathDistancePlot	Path distances plot	SIMILARITY	PLOTS=DISTANCES
PathDistanceHistogram	Path distances histogram	SIMILARITY	PLOTS=DISTANCES
PathRelativeDistancePlot	Path relative distances plot	SIMILARITY	PLOTS=DISTANCES
PathRelativeDistanceHistogram	Path relative distances histogram	SIMILARITY	PLOTS=DISTANCES
PathPlot	Path plot	SIMILARITY	PLOTS=PATHS
PathSequencesPlot	Path sequences plot	SIMILARITY	PLOTS=MAPS
PathSequencesScaledPlot	Scaled path sequences map plot	SIMILARITY	PLOTS=MAPS
SequencePlot	Sequence plot	SIMILARITY	PLOTS=SEQUENCES
SeriesPlot	Input time series plot	SIMILARITY	PLOTS=INPUTS
SimilarityPlot	Similarity measures plot	SIMILARITY	PLOTS=MEASURES
TargetSequencePlot	Target sequence plot	SIMILARITY	PLOTS=TARGETS
WarpPlot	Warping plot	SIMILARITY	PLOTS=WARPS
ScaledWarpPlot	Scaled warping plot	SIMILARITY	PLOTS=WARPS

Time Series Plots

The time series plots (SeriesPlot) illustrate the input time series to be compared. The horizontal axis represents the input series time ID values, and the vertical axis represents the input series values.

Sequence Plots

The sequence plots (SequencePlot) illustrate the target and input sequences to be compared. The horizontal axis represents the (target or input) sequence index, and the vertical axis represents the (target or input) sequence values.

Path Plots

The path plot (PathPlot) and path limits plot (PathLimitsPlot) illustrate the path through the distance matrix. The horizontal axis represents the input sequence index, and the vertical axis represents the target sequence index. The dots represent the path coordinates. The upper parallel line represents the compression limit, and the lower parallel line represents the expansion limit. These plots visualize the path through the distance matrix. Vertical movements indicate compression, and horizontal movements represent expansion of the target sequence with respect to the input sequence. These plots are useful for visualizing the amount of expansion and compression along the path.

Time Warp Plots

The time warp plot (WarpPlot) and scaled time warp plot (ScaledWarpPlot) illustrate the time warping. The horizontal axis represents the (input and target) sequence index. The upper line plot represents the target sequence. The lower line plot represents the input sequence. The lines that connect the input and target sequence values represent the mapping between the input and target sequence indices along the optimal path. These plots visualize the warping of the time index with respect to the input and target sequence values. Expansion of a single target sequence value occurs when it is mapped to more than one input sequence value. Expansion of a single input sequence value occurs when it is mapped to more than one target sequence value. The plots are useful for visualizing the mapping between the input and target sequence values along the path. The plots are useful for comparing the path sequences or input and target sequence after time warping.

Path Sequence Plots

The path sequence plot (PathSequencesPlot) and scaled path sequence plot (PathSequencesScaled-Plot) illustrate the sequence mapping along the optimal path. The horizontal axis represents the path index. The dashed line represents the time warped input sequence. The solid line represents the time warped target sequence. These plots visualize the mapping between the input and target sequence values with respect to the path index. The scaled plot with the input and target sequence values are scaled and evenly separated for visual convenience.

Path Distance Plots

The path distance plots (PathDistancePlot) and path relative distance plots (PathRelativeDistancePlot) illustrate the path (relative) distances. The horizontal axis represents the path index. The vertical needles represent the (relative) distances. The horizontal reference lines indicate one and two standard deviations.

The path distance histogram (PathDistanceHistogram) and path relative distance histogram (PathDistanceRelativeHistogram) illustrate the distribution of the path (relative) distances. The bars represent the histogram, and the solid line represents a normal distribution with the same mean and variance.

Cost Plots

The cost plot (CostPlot) and cost limits plot (CostPlot) illustrate the cost of traversing the distance matrix. The horizontal axis represents the input sequence index, and the vertical axis represents the target sequence index. The colors and shading within the plot illustrate the incremental cost of traversing the distance matrix. The upper parallel line represents the compression limit, and the lower parallel line represents the expansion limit.

Examples: SIMILARITY Procedure

Example 23.1: Accumulating Transactional Data into Time Series Data

This example uses the SIMILARITY procedure to illustrate the accumulation of time-stamped transactional data that has been recorded at no particular frequency into time series data at a specific frequency. After the time series is created, the various SAS/ETS procedures related to time series analysis, similarity analysis, seasonal adjustment and decomposition, modeling, and forecasting can be used to further analyze the time series data.

Suppose that the input data set WORK.RETAIL contains variables STORE and TIMESTAMP and numerous other numeric transaction variables. The BY variable STORE contains values that break up the transactions into groups (BY groups). The time ID variable TIMESTAMP contains SAS date values recorded at no particular frequency. The other data set variables contain the numeric transaction values to be analyzed. It is further assumed that the input data set is sorted by the variables STORE and TIMESTAMP.

The following statements form monthly time series from the transactional data based on the median value (ACCUMULATE=MEDIAN) of the transactions recorded with each time period. The accumulated time series values for time periods with no transactions are set to zero instead of missing (SETMISS=0). Only transactions recorded between the first day of 1998 (START='01JAN1998'D) and last day of 2000 (END='31JAN2000'D) are considered and if needed are extended to include this range.

```

proc similarity data=work.retail out=mseries;
  by store;
  id timestamp interval=month
      accumulate=median
      setmiss=0
      start='01jan1998'd
      end  ='31dec2000'd;
  target _NUMERIC_;
run;

```

The monthly time series data are stored in the data WORK.MSERIES. Each BY group associated with the BY variable STORE contains an observation for each of the 36 months associated with the years 1998, 1999, and 2000. Each observation contains the variable STORE, TIMESTAMP, and each of the analysis variables in the input DATA= data set.

After each set of transactions has been accumulated to form the corresponding time series, the accumulated time series can be analyzed by using various time series analysis techniques. For example, exponentially weighted moving averages can be used to smooth each series. The following statements use the EXPAND procedure to smooth the analysis variable named STOREITEM.

```

proc expand data=mseries
  out=smoothed
  from=month;
  by store;
  id timestamp;
  convert storeitem=smooth / transform=(ewma 0.1);
run;

```

The smoothed series is stored in the data set WORK.SMOOTHED. The variable SMOOTH contains the smoothed series.

If the time ID variable TIMESTAMP contains SAS datetime values instead of SAS date values, the INTERVAL=, START=, and END= options in the SIMILARITY procedure must be changed accordingly, and the following statements could be used to accumulate the datetime transactions to a monthly interval:

```

proc similarity data=work.retail
  out=tseries;
  by store;
  id timestamp interval=dtmonth
      accumulate=median
      setmiss=0
      start='01jan1998:00:00:00'dt
      end  ='31dec2000:00:00:00'dt;
  target _NUMERIC_;
run;

```

The monthly time series data are stored in the data WORK.TSERIES, and the time ID values use a SAS datetime representation.

Example 23.2: Similarity Analysis

This simple example illustrates how to use similarity analysis to compare two time sequences. The following statements create an example data set that contains two time sequences of differing lengths:

```
data test;
input i y x;
datalines;
1 2 3
2 4 5
3 6 3
4 7 3
5 3 3
6 8 6
7 9 3
8 3 8
9 10 .
10 11 .
;
run;
```

The following statements perform similarity analysis on the example data set:

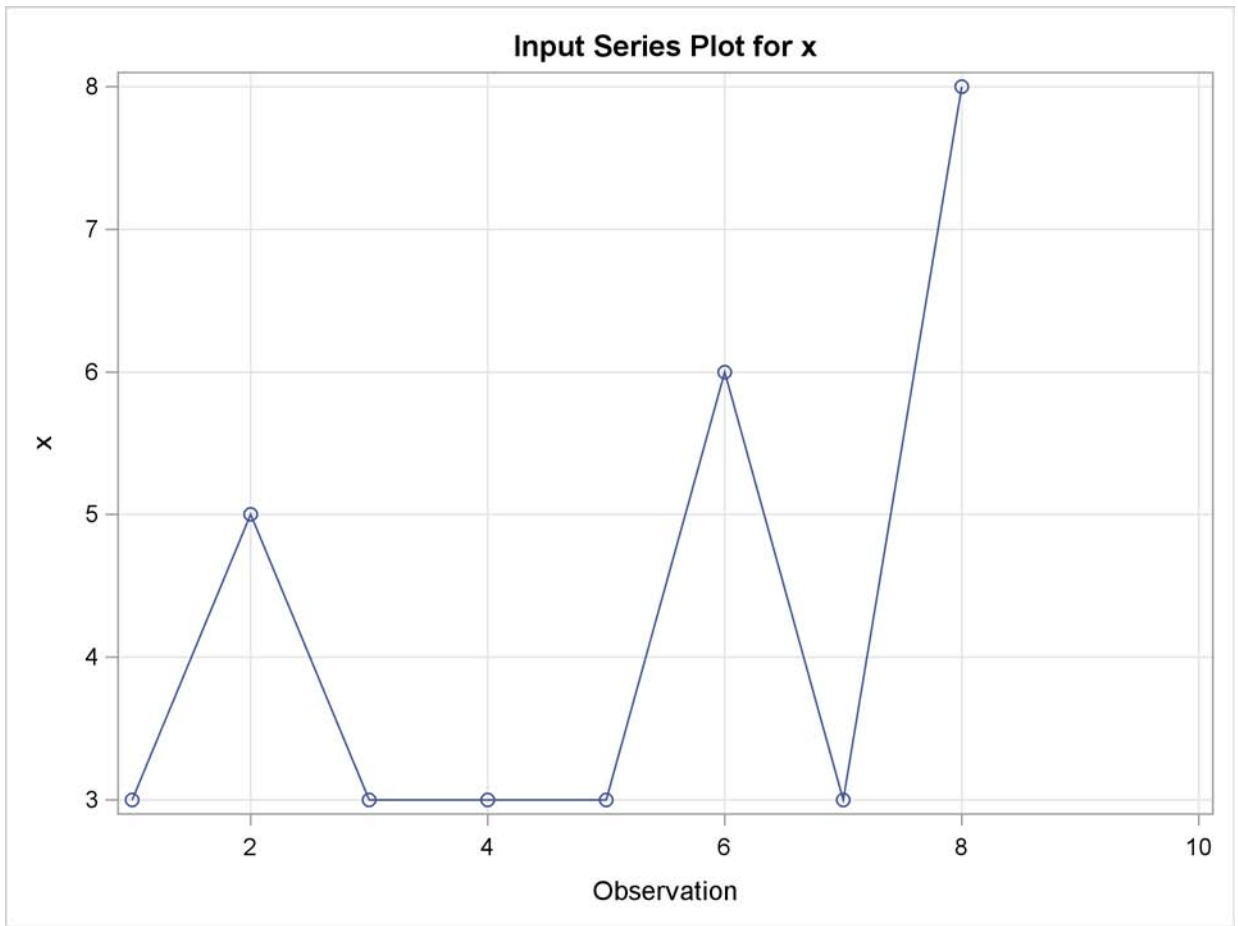

```
ods graphics on;
proc similarity data=test out=_null_
  print=all plot=all;
  input x;
  target y / measure=absdev;
run;
```

The DATA=TEST option specifies that the input data set WORK.TEST is to be used in the analysis. The OUT=_NULL_ option specifies that no output time series data set is to be created. The PRINT=ALL and PLOTS=ALL options specify that all ODS tables and graphs are to be produced. The INPUT statement specifies that the input variable is X. The TARGET statement specifies that the target variable is Y and that the similarity measure is computed using absolute deviation (MEASURE=ABSDEV).

Output 23.2.16 Time Warp Plot

Output 23.2.17 Time Warp Scaled Plot

The following statements repeat the preceding similarity analysis on the example data set with warping limits:

```
ods graphics on;
proc similarity data=test out=_null_
  print=all plot=all;
  input x;
  target y / measure=absdev
  compress=(localabs=2)
  expand=(localabs=2);
run;
```

The COMPRESS=(LOCALABS=2) option limits local absolute compression to 2. The EXPAND=(LOCALABS=2) option limits local absolute expansion to 2.

Output 23.2.18 Path Plot with Warping Limits

Output 23.2.19 Warped Path Limits

Path Limits					
Limit	Specified Absolute	Specified Percentage	Minimum Allowed	Maximum Allowed	Applied
Compression	2	None	2	9	2
Expansion	2	None	0	7	2

Output 23.2.20 Cost Plot with Warping Limits

The following statements repeat the preceding similarity analysis on the example data set but store the results in output data sets:

```
proc similarity data=test out=series
  outsequence=sequences outpath=path outsum=summary;
  input x;
  target y / measure=absdev
  compress=(localabs=2)
  expand=(localabs=2);
run;
```

The `OUT=SERIES`, `OUTSEQUENCE=SEQUENCES`, `OUTPATH=PATH`, and `OUTSUM=SUMMARY` options specify that the output time series, time sequences, path analysis, and summary data sets be created, respectively.

Example 23.3: Sliding Similarity Analysis

This example illustrates how to use sliding similarity analysis to compare two time sequences. The SASHELP.WORKERS data set contains two similar time series variables (ELECTRIC and MASONRY), which represent employment over time. The following statements create an example data set that contains two time series of differing lengths, where the variable MASONRY has the first 12 and last 7 observations set to missing to simulate the lack of data associated with the target series:

```
data workers; set sashelp.workers;
  if '01JAN1978'D <= date < '01JAN1982'D then masonry = masonry;
  else masonry = .;
run;
```

The goal of sliding similarity measures analysis is find the slide index that corresponds to the most similar subsequence of the input series when compared to the target sequence. The following statements perform sliding similarity analysis on the example data set:

```
proc similarity data=workers out=_NULL_ print=(slides summary);
  id date interval=month;
  input electric;
  target masonry / slide=index measure=msqrdev
                  expand=(localabs=3 globalabs=3)
                  compress=(localabs=3 globalabs=3);
run;
```

The DATA=WORKERS option specifies that the input data set WORK.WORKERS is to be used in the analysis. The OUT=_NULL_ option specifies that no output time series data set is to be created. The PRINT=(SLIDES SUMMARY) option specifies that the ODS tables related to the sliding similarity measures and their summary be produced. The INPUT statement specifies that the input variable is ELECTRIC. The TARGET statement specifies that the target variable is MASONRY and that the similarity measure be computed using mean squared deviation (MEASURE=MSQRDEV). The SLIDE=INDEX option specifies observation index sliding. The COMPRESS=(LOCALABS=3 GLOBALABS=3) option limits local and global absolute compression to 3. The EXPAND=(LOCALABS=3 GLOBALABS=3) option limits local and global absolute expansion to 3.

Output 23.3.1 Summary of the Slide Measures

The SIMILARITY Procedure					
Slide Measures Summary for Input=ELECTRIC and Target=MASONRY					
Slide Index	DATE	Slide Target Sequence Length	Slide Input Sequence Length	Slide Warping Amount	Slide Minimum Measure
0	JAN1977	48	51	3	497.6737
1	FEB1977	48	51	1	482.6777
2	MAR1977	48	51	0	474.1251
3	APR1977	48	51	0	490.7792
4	MAY1977	48	51	-2	533.0788

6	JUL1977	48	51	-3	701.7138
7	AUG1977	48	51	3	646.5918
8	SEP1977	48	51	3	616.3258
9	OCT1977	48	51	3	510.9836
10	NOV1977	48	51	3	382.1434
11	DEC1977	48	51	3	340.4702
12	JAN1978	48	51	2	327.0572
13	FEB1978	48	51	1	322.5460
14	MAR1978	48	51	0	325.2689
15	APR1978	48	51	-1	351.4161
16	MAY1978	48	51	-2	398.0490
17	JUN1978	48	50	-3	471.6931
18	JUL1978	48	49	-3	590.8089
19	AUG1978	48	48	0	595.2538
20	SEP1978	48	47	-1	689.2233
21	OCT1978	48	46	-2	745.8891
22	NOV1978	48	45	-3	679.1907

Output 23.3.2 Minimum Measure

Minimum Measure Summary	
Input Variable	MASONRY
ELECTRIC	322.5460

This analysis results in 23 slides based on the observation index. The minimum measure (322.5460) occurs at slide index 13 which corresponds to the time value FEB1978. Note that the original data set SASHELP.WORKERS was modified beginning at the time value JAN1978. This similarity analysis justifies the belief the ELECTRIC lags MASONRY by one month based on the time series cross-correlation analysis despite the lack of target data (MASONRY).

The goal of seasonal sliding similarity measures is to find the seasonal slide index that corresponds to the most similar seasonal subsequence of the input series when compared to the target sequence. The

following statements repeat the preceding similarity analysis on the example data set with seasonal sliding:

```
proc similarity data=workers out=_NULL_ print=(slides summary);
  id date interval=month;
  input electric;
  target masonry / slide=season measure=msqrdev;
run;
```

Output 23.3.3 Summary of the Seasonal Slide Measures

The SIMILARITY Procedure					
Slide Measures Summary for Input=ELECTRIC and Target=MASONRY					
Slide Index	DATE	Slide Target Sequence Length	Slide Input Sequence Length	Slide Warping Amount	Slide Minimum Measure
0	JAN1977	48	48	0	1040.086
12	JAN1978	48	48	0	641.927

Output 23.3.4 Seasonal Minimum Measure

Minimum Measure Summary	
Input Variable	Minimum Measure
MASONRY	
ELECTRIC	641.9273

The analysis differs from the previous analysis in that the slides are performed based on the seasonal index (SLIDE=SEASON) with no warping. With a seasonality of 12, two seasonal slides are considered at slide indices 0 and 12 with the minimum measure (641.9273) occurring at slide index 12 which corresponds to the time value JAN1978. Note that the original data set SASHELP.WORKERS was modified beginning at the time value JAN1978. This similarity analysis justifies the belief that ELECTRIC and MASONRY have similar seasonal properties based on seasonal decomposition analysis despite the lack of target data (MASONRY).

Example 23.4: Searching for Historical Analogies

This example illustrates how to search for historical analogies by using seasonal sliding similarity analysis of transactional time-stamped data. The SASHELP.TIMEDATA data set contains the variable (VOLUME), which represents activity over time. The following statements create an example data

set that contains two time series of differing lengths, where the variable HISTORY represents the historical activity and RECENT represents the more recent activity:

```
data timedata; set sashelp.timedata;
  drop volume;
  recent = .;
  history = volume;
  if datetime >= '20AUG2000:00:00:00'DT then do;
    recent = volume;
    history = .;
  end;
run;
```

The goal of seasonal sliding similarity measures is to find the seasonal slide index that corresponds to the most similar seasonal subsequence of the input series when compared to the target sequence. The following statements perform similarity analysis on the example data set with seasonal sliding:

```
proc similarity data=timedata out=_NULL_ outsequence=sequences
  outsum=summary;
  id datetime interval=dtday accumulate=total
  start='27JUL1997:00:00:00'dt end='21OCT2000:11:59:59'DT;
  input history / normalize=absolute;
  target recent / slide=season normalize=absolute measure=mabsdev;
run;
```

The DATA=TIMEDATA option specifies that the input data set WORK.TIMEDATA be used in the analysis. The OUT=_NULL_ option specifies that no output time series data set is to be created. The OUTSEQUENCE=SEQUENCES and OUTSUM=SUMMARY options specify the output sequences and summary data sets, respectively. The ID statement specifies that the time ID variable is DATETIME, which is to be accumulated on a daily basis (INTERVAL=DTDAY) by summing the transactions (ACCUMULATE=TOTAL). The ID statement also specifies that the data is accumulated on the weekly boundaries starting on the week of 27JUL1997 and ending on the week of 15OCT2000 (START='27JUL1997:00:00:00'DT END='21OCT2000:11:59:59'DT'). The INPUT statement specifies that the input variable is HISTORY, which is to be normalized using absolute normalization (NORMALIZE=ABSOLUTE). The TARGET statement specifies that the target variable is RECENT, which is to be normalized by using absolute normalization (NORMALIZE=ABSOLUTE) and that the similarity measure be computed by using mean absolute deviation (MEASURE=MABSDEV). The SLIDE=SEASON options specifies season index sliding.

To illustrate the results of the similarity analysis, the output sequence data set must be subset by using the output summary data set.

```
data _NULL_; set summary;
  call symput('MEASURE', left(trim(putn(recent, 'BEST20.'))));
run;

data result; set sequences;
  by _SLIDE_;
  retain flag 0;
  if first._SLIDE_ then do;
    if (&measure - 0.00001 < _SIM_ < &measure + 0.00001)
      then flag = 1;
  end;
```

```

end;
if flag then output;
if last._SLIDE_ then flag = 0;
run;

```

The following statements generate a cross series plot of the results:

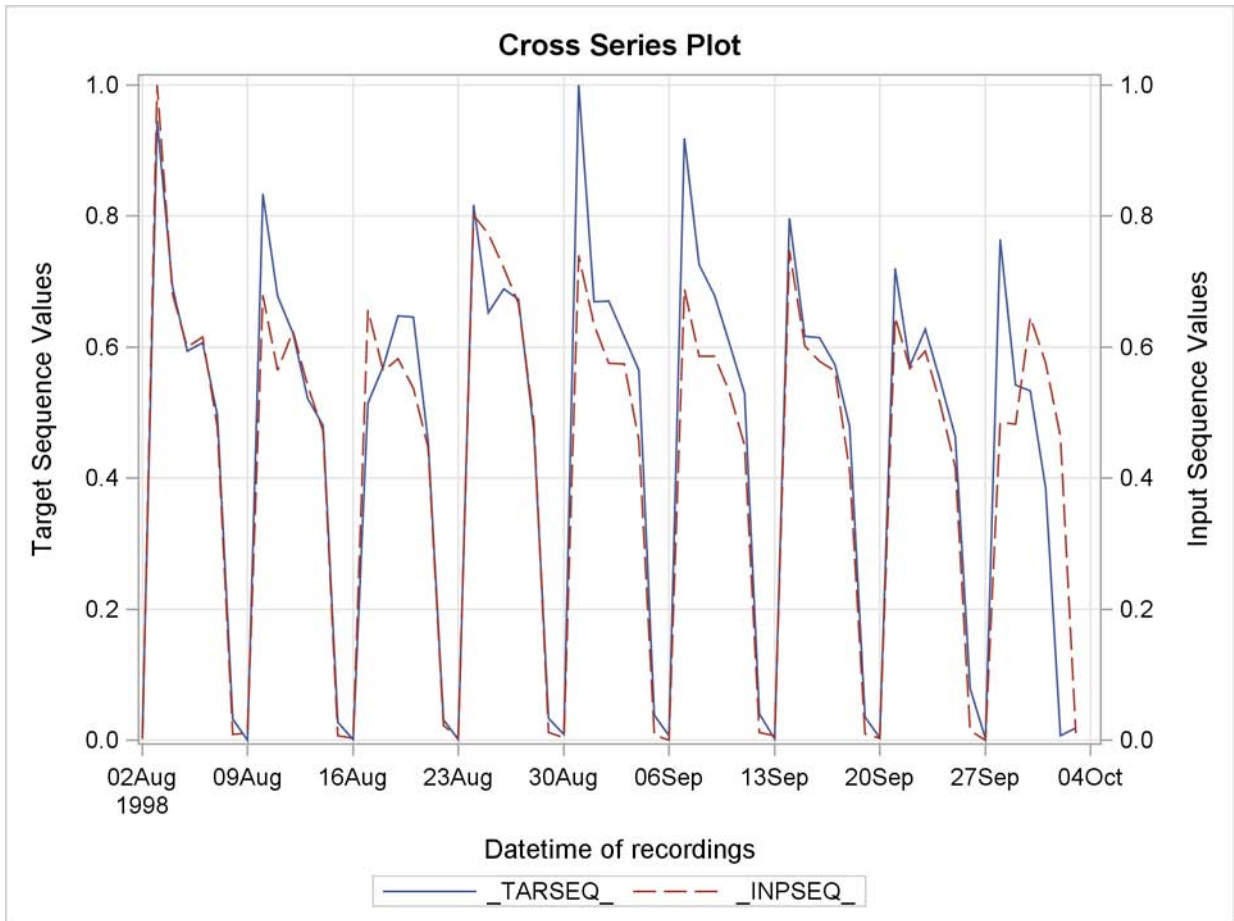

```

proc timeseries data=result out=_NULL_ crossplot=series;
id datetime interval=dtday;
var _TARSEQ_;
crossvar _INPSEQ_;
run;

```

The cross series plot illustrates that the historical time series analogy most similar to the most recent time series data that started on 20AUG2000 occurred on 02AUG1998.

Output 23.4.1 Cross Series Plot of the Historical Time Series

Overview: SIMLIN Procedure

The SIMLIN procedure reads the coefficients for a set of linear structural equations, which are usually produced by the SYSLIN procedure. PROC SIMLIN then computes the reduced form and, if

input data are given, uses the reduced form equations to generate predicted values. PROC SIMLIN is especially useful when dealing with sets of structural difference equations. The SIMLIN procedure can perform simulation or forecasting of the endogenous variables.

The SIMLIN procedure can be applied only to models that are:

- linear with respect to the parameters
- linear with respect to the variables
- square (as many equations as endogenous variables)
- nonsingular (the coefficients of the endogenous variables form an invertible matrix)

Getting Started: SIMLIN Procedure

The SIMLIN procedure processes the coefficients in a data set created by the SYSLIN procedure using the OUTEST= option or by another regression procedure such as PROC REG. To use PROC SIMLIN you must first produce the coefficient data set and then specify this data set on the EST= option of the PROC SIMLIN statement. You must also tell PROC SIMLIN which variables are endogenous and which variables are exogenous. List the endogenous variables in an ENDOGENOUS statement, and list the exogenous variables in an EXOGENOUS statement.

The following example illustrates the creation of an OUTEST= data set with PROC SYSLIN and the computation and printing of the reduced form coefficients for the model with PROC SIMLIN.

```
proc syslin data=in outest=e;
  model y1 = y2 x1;
  model y2 = y1 x2;
run;

proc simlin est=e;
  endogenous y1 y2;
  exogenous x1 x2;
run;
```

If the model contains lagged endogenous variables you must also use a LAGGED statement to tell PROC SIMLIN which variables contain lagged values, which endogenous variables they are lags of, and the number of periods of lagging. For dynamic models, the TOTAL and INTERIM= options can be used on the PROC SIMLIN statement to compute and print total and impact multipliers. (See "Dynamic Multipliers" later in this section for an explanation of multipliers.)

In the following example the variables Y1LAG1, Y2LAG1, and Y2LAG2 contain lagged values of the endogenous variables Y1 and Y2. Y1LAG1 and Y2LAG1 contain values of Y1 and Y2 for the previous observation, while Y2LAG2 contains 2 period lags of Y2. The LAGGED statement specifies the lagged relationships, and the TOTAL and INTERIM= options request multiplier analysis.

The INTERIM=2 option prints matrices showing the impact that changes to the exogenous variables have on the endogenous variables after 1 and 2 periods.

```

data in; set in;
  y1lag1 = lag(y1);
  y2lag1 = lag(y2);
  y2lag2 = lag2(y2);
run;

proc syslin data=in outest=e;
  model y1 = y2 y1lag1 y2lag2 x1;
  model y2 = y1 y2lag1 x2;
run;

proc simlin est=e total interim=2;
  endogenous y1 y2;
  exogenous x1 x2;
  lagged y1lag1 y1 1 y2lag1 y2 1 y2lag2 y2 2;
run;

```

After the reduced form of the model is computed, the model can be simulated by specifying an input data set on the PROC SIMLIN statement and using an OUTPUT statement to write the simulation results to an output data set. The following example modifies the PROC SIMLIN step from the preceding example to simulate the model and stores the results in an output data set.

```

proc simlin est=e total interim=2 data=in;
  endogenous y1 y2;
  exogenous x1 x2;
  lagged y1lag1 y1 1 y2lag1 y2 1 y2lag2 y2 2;
  output out=sim predicted=y1hat y2hat
         residual=y1resid y2resid;
run;

```

Prediction and Simulation

If an input data set is specified with the DATA= option in the PROC SIMLIN statement, the procedure reads the data and uses the reduced form equations to compute predicted and residual values for each of the endogenous variables. (If no data set is specified with the DATA= option, no simulation of the system is performed, and only the reduced form and multipliers are computed.)

The character of the prediction is based on the START= value. Until PROC SIMLIN encounters the START= observation, actual endogenous values are found and fed into the lagged endogenous terms. Once the START= observation is reached, dynamic simulation begins, where predicted values are fed into lagged endogenous terms until the end of the data set is reached.

The predicted and residual values generated here are different from those produced by the SYSLIN procedure since PROC SYSLIN uses the structural form with actual endogenous values. The

predicted values computed by the SIMLIN procedure solve the simultaneous equation system. These reduced-form predicted values are functions only of the exogenous and lagged endogenous variables and do not depend on actual values of current period endogenous variables.

Syntax: SIMLIN Procedure

The following statements can be used with PROC SIMLIN:

```

PROC SIMLIN options ;
  BY variables ;
  ENDOGENOUS variables ;
  EXOGENOUS variables ;
  ID variables ;
  LAGGED lag-var endogenous-var number ellipsis ;
  OUTPUT OUT=SAS-data-set options ;

```

Functional Summary

The statements and options controlling the SIMLIN procedure are summarized in the following table.

Description	Statement	Option
Data Set Options		
specify input data set containing structural coefficients	PROC SIMLIN	EST=
specify type of estimates read from EST= data set	PROC SIMLIN	TYPE=
write reduced form coefficients and multipliers to an output data set	PROC SIMLIN	OUTEST=
specify the input data set for simulation	PROC SIMLIN	DATA=
write predicted and residual values to an output data set	OUTPUT	
Printing Control Options		
print the structural coefficients	PROC SIMLIN	ESTPRINT
suppress printing of reduced form coefficients	PROC SIMLIN	NORED
suppress all printed output	PROC SIMLIN	NOPRINT
Dynamic Multipliers		
compute interim multipliers	PROC SIMLIN	INTERIM=
compute total multipliers	PROC SIMLIN	TOTAL

Description	Statement	Option
Declaring the Role of Variables		
specify BY-group processing	BY	
specify the endogenous variables	ENDOGENOUS	
specify the exogenous variables	EXOGENOUS	
specify identifying variables	ID	
specify lagged endogenous variables	LAGGED	
Controlling the Simulation		
specify the starting observation for dynamic simulation	PROC SIMLIN	START=

PROC SIMLIN Statement

PROC SIMLIN *options* ;

The following options can be used in the PROC SIMLIN statement:

DATA= *SAS-data-set*

specifies the SAS data set containing input data for the simulation. If the DATA= option is used, the data set specified must supply values for all exogenous variables throughout the simulation. If the DATA= option is not specified, no simulation of the system is performed, and only the reduced form and multipliers are computed.

EST= *SAS-data-set*

specifies the input data set containing the structural coefficients of the system. If EST= is omitted the most recently created SAS data set is used. The EST= data set is normally a "TYPE=EST" data set produced by the OUTEST= option of PROC SYSLIN. However, you can also build the EST= data set with a SAS DATA step. See "The EST= Data Set" later in this chapter for details.

ESTPRINT

prints the structural coefficients read from the EST= data set.

INTERIM= *n*

requests that interim multipliers be computed for interims 1 through *n*. If not specified, no interim multipliers are computed. This feature is available only if there are no lags greater than 1.

NOPRINT

suppresses all printed output.

NORED

suppresses the printing of the reduced form coefficients.

OUTEST= *SAS-data-set*

specifies an output SAS data set to contain the reduced form coefficients and multipliers, in addition to the structural coefficients read from the EST= data set. The OUTEST= data set has the same form as the EST= data set. If the OUTEST= option is not specified, the reduced form coefficients and multipliers are not written to a data set.

START= *n*

specifies the observation number in the DATA= data set where the dynamic simulation is to be started. By default, the dynamic simulation starts with the first observation in the DATA= data set for which all variables (including lags) are not missing.

TOTAL

requests that the total multipliers be computed. This feature is available only if there are no lags greater than 1.

TYPE= *value*

specifies the type of estimates to be read from the EST= data set. The TYPE= value must match the value of the `_TYPE_` variable for the observations that you want to select from the EST= data set (TYPE=2SLS, for example).

BY Statement

BY *variables ;*

A BY statement can be used with PROC SIMLIN to obtain separate analyses for groups of observations defined by the BY variables.

The BY statement can be applied to one or both of the EST= and the DATA= input data set. When a BY statement is used and both an EST= and a DATA= input data set are specified, PROC SIMLIN checks to see if one or both of the data sets contain the BY variables.

Thus, there are three ways of using the BY statement with PROC SIMLIN:

1. If the BY variables are found in the EST= data set only, PROC SIMLIN simulates over the entire DATA= data set once for each set of coefficients read from the BY groups in the EST= data set.
2. If the BY variables are found in the DATA= data set only, PROC SIMLIN performs separate simulations over each BY group in the DATA= data set, using the single set of coefficients in the EST= data set.
3. If the BY variables are found in both the EST= and the DATA= data sets, PROC SIMLIN performs separate simulations over each BY group in the DATA= data set using the coefficients from the corresponding BY group in the EST= data set.

ENDOGENOUS Statement

ENDOGENOUS *variables ;*

List the names of the endogenous (jointly dependent) variables in the ENDOGENOUS statement. The ENDOGENOUS statement can be abbreviated as ENDOG or ENDO.

EXOGENOUS Statement

EXOGENOUS *variables ;*

List the names of the exogenous (independent) variables in the EXOGENOUS statement. The EXOGENOUS statement can be abbreviated as EXOG or EXO.

ID Statement

ID *variables ;*

The ID statement can be used to restrict the variables copied from the DATA= data set to the OUT= data set. Use the ID statement to list the variables you want copied to the OUT= data set besides the exogenous, endogenous, lagged endogenous, and BY variables. If the ID statement is omitted, all the variables in the DATA= data set are copied to the OUT= data set.

LAGGED Statement

LAGGED *lag-var endogenous-var number ellipsis ;*

For each lagged endogenous variable, specify the name of the lagged variable, the name of the endogenous variable that was lagged, and the degree of the lag. Only one LAGGED statement is allowed.

The following is an example of the use of the LAGGED statement:

```
proc simlin est=e;
  endog y1 y2;
  lagged y1lag1 y1 1 y2lag1 y2 1 y2lag3 y2 3;
run;
```

This statement specifies that the variable Y1LAG1 contains the values of the endogenous variable Y1 lagged one period; the variable Y2LAG1 refers to the values of Y2 lagged one period; and the variable Y2LAG3 refers to the values of Y2 lagged three periods.

OUTPUT Statement

OUTPUT *OUT= SAS-data-set options ;*

The OUTPUT statement specifies that predicted and residual values be put in an output data set. A DATA= input data set must be supplied if the OUTPUT statement is used, and only one OUTPUT statement is allowed. The following options can be used in the OUTPUT statement:

OUT= *SAS-data-set*

names the output SAS data set to contain the predicted values and residuals. If OUT= is not specified, the output data set is named using the DATA*n* convention.

PREDICTED= *names*

P= *names*

names the variables in the output data set that contain the predicted values of the simulation. These variables correspond to the endogenous variables in the order in which they are specified in the ENDOGENOUS statement. Specify up to as many names as there are endogenous variables. If you specify names on the PREDICTED= option for only some of the endogenous variables, predicted values for the remaining variables are not output. The names must not match any variable name in the input data set.

RESIDUAL= *names*

R= *names*

names the variables in the output data set that contain the residual values from the simulation. The residuals are the differences between the actual values of the endogenous variables from the DATA= data set and the predicted values from the simulation. These variables correspond to the endogenous variables in the order in which they are specified in the ENDOGENOUS statement. Specify up to as many names as there are endogenous variables. The names must not match any variable name in the input data set.

The following is an example of the use of the OUTPUT statement. This example outputs predicted values for Y1 and Y2 and outputs residuals for Y1.

```
proc simlin est=e;
  endog y1 y2;
  output out=b predicted=y1hat y2hat
          residual=y1resid;
run;
```

Details: SIMLIN Procedure

The following sections explain the structural and reduced forms, dynamic multipliers, input data sets, and the model simulation process in more detail.

Defining the Structural Form

An EST= input data set supplies the coefficients of the equation system. The data set containing the coefficients is normally a "TYPE=EST" data set created by the OUTEST= option of PROC SYSLIN or another regression procedure. The data set contains the special variables _TYPE_, _DEPVAR_, and INTERCEPT. You can also supply the structural coefficients of the system to PROC SIMLIN in a data set produced by a SAS DATA step as long as the data set is of the form TYPE=EST. Refer to SAS/STAT software documentation for a discussion of the special TYPE=EST type of SAS data set.

Suppose that there is a $g \times 1$ vector of endogenous variables \mathbf{y}_t , an $l \times 1$ vector of lagged endogenous variables \mathbf{y}_t^L , and a $k \times 1$ vector of exogenous variables \mathbf{x}_t , including the intercept. Then, there are g structural equations in the simultaneous system that can be written

$$\mathbf{G}\mathbf{y}_t = \mathbf{C}\mathbf{y}_t^L + \mathbf{B}\mathbf{x}_t$$

where \mathbf{G} is the matrix of coefficients of current period endogenous variables, \mathbf{C} is the matrix of coefficients of lagged endogenous variables, and \mathbf{B} is the matrix of coefficients of exogenous variables. \mathbf{G} is assumed to be nonsingular.

Computing the Reduced Form

First, the SIMLIN procedure computes reduced form coefficients by premultiplying by \mathbf{G}^{-1} :

$$\mathbf{y}_t = \mathbf{G}^{-1}\mathbf{C}\mathbf{y}_t^L + \mathbf{G}^{-1}\mathbf{B}\mathbf{x}_t$$

This can be written as

$$\mathbf{y}_t = \Pi_1\mathbf{y}_t^L + \Pi_2\mathbf{x}_t$$

where $\Pi_1 = \mathbf{G}^{-1}\mathbf{C}$ and $\Pi_2 = \mathbf{G}^{-1}\mathbf{B}$ are the reduced form coefficient matrices.

The reduced form matrices $\Pi_1 = \mathbf{G}^{-1}\mathbf{C}$ and $\Pi_2 = \mathbf{G}^{-1}\mathbf{B}$ are printed unless the NORED option is specified in the PROC SIMLIN statement. The structural coefficient matrices \mathbf{G} , \mathbf{C} , and \mathbf{B} are printed when the ESTPRINT option is specified.

Dynamic Multipliers

For models that have only first-order lags, the equation of the reduced form of the system can be rewritten

$$\mathbf{y}_t = \mathbf{D}\mathbf{y}_{t-1} + \Pi_2\mathbf{x}_t$$

\mathbf{D} is a matrix formed from the columns of Π_1 plus some columns of zeros, arranged in the order in which the variables meet the lags. The elements of Π_2 are called *impact multipliers* because they

show the immediate effect of changes in each exogenous variable on the values of the endogenous variables. This equation can be rewritten as

$$\mathbf{y}_t = \mathbf{D}^2 \mathbf{y}_{t-2} + \mathbf{D} \Pi_2 \mathbf{x}_{t-1} + \Pi_2 \mathbf{x}_t$$

The matrix formed by the product $\mathbf{D} \Pi_2$ shows the effect of the exogenous variables one lag back; the elements in this matrix are called *interim multipliers* and are computed and printed when the INTERIM= option is specified in the PROC SIMLIN statement. The i th period interim multipliers are formed by $\mathbf{D}^i \Pi_2$.

The series can be expanded as

$$\mathbf{y}_t = \mathbf{D}^\infty \mathbf{y}_{t-\infty} + \sum_{i=0}^{\infty} \mathbf{D}^i \Pi_2 \mathbf{x}_{t-i}$$

A permanent and constant setting of a value for x has the following cumulative effect:

$$\left(\sum_{i=0}^{\infty} \mathbf{D}^i \right) \Pi_2 \mathbf{x} = (\mathbf{I} - \mathbf{D})^{-1} \Pi_2 \mathbf{x}$$

The elements of $(\mathbf{I} - \mathbf{D})^{-1} \Pi_2$ are called the *total multipliers*. Assuming that the sum converges and that $(\mathbf{I} - \mathbf{D})$ is invertible, PROC SIMLIN computes the total multipliers when the TOTAL option is specified in the PROC SIMLIN statement.

Multipliers for Higher Order Lags

The dynamic multiplier options require the system to have no lags of order greater than one. This limitation can be circumvented, since any system with lags greater than one can be rewritten as a system where no lag is greater than one by forming new endogenous variables that are single-period lags.

For example, suppose you have the third-order single equation

$$y_t = ay_{t-3} + b\mathbf{x}_t$$

This can be converted to a first-order three-equation system by introducing two additional endogenous variables, $y_{1,t}$ and $y_{2,t}$, and computing corresponding first-order lagged variables for each endogenous variable: y_{t-1} , $y_{1,t-1}$, and $y_{2,t-1}$. The higher order lag relations are then produced by adding identities to link the endogenous and identical lagged endogenous variables:

$$y_{1,t} = y_{t-1}$$

$$y_{2,t} = y_{1,t-1}$$

$$y_t = ay_{2,t-1} + b\mathbf{x}_t$$

This conversion using the SYSLIN and SIMLIN procedures requires three steps:

1. Add the extra endogenous and lagged endogenous variables to the input data set using a DATA step. Note that two copies of each lagged endogenous variable are needed for each lag reduced, one to serve as an endogenous variable and one to serve as a lagged endogenous variable in the reduced system.
2. Add IDENTITY statements to the PROC SYSLIN step to equate each added endogenous variable to its lagged endogenous variable copy.
3. In the PROC SIMLIN step, declare the added endogenous variables in the ENDOGENOUS statement and define the lag relations in the LAGGED statement.

See [Example 24.2](#) for an illustration of how to convert an equation system with higher-order lags into a larger system with only first-order lags.

EST= Data Set

Normally, PROC SIMLIN uses an EST= data set produced by PROC SYSLIN with the OUTEST= option. This data set is in the form expected by PROC SIMLIN. If there is more than one set of estimates produced by PROC SYSLIN, you must use the TYPE= option in the PROC SIMLIN statement to select the set to be simulated. Then PROC SIMLIN reads from the EST= data set only those observations with a _TYPE_ value corresponding to the TYPE= option (for example, TYPE=2SLS) or with a _TYPE_ value of IDENTITY.

The SIMLIN procedure can only solve square, nonsingular systems. If you have fewer equations than endogenous variables, you must specify IDENTITY statements in the PROC SYSLIN step to bring the system up to full rank. If there are g endogenous variables and $m < g$ stochastic equations with unknown parameters, then you use m MODEL statements to specify the equations with parameters to be estimated and you must use $g-m$ IDENTITY statements to complete the system.

You can build your own EST= data set with a DATA step rather than use PROC SYSLIN. The EST= data set must contain the endogenous variables, the lagged endogenous variables (if any), and the exogenous variables in the system (if any). If any of the equations have intercept terms, the variable INTERCEPT must supply these coefficients. The EST= data set should also contain the special character variable comp _DEPVAR_ to label the equations.

The EST= data set must contain one observation for each equation in the system. The values of the lagged endogenous variables must contain the **C** coefficients. The values of the exogenous variables and the INTERCEPT variable must contain the **B** coefficients. The values of the endogenous variables, however, must contain the negatives of the **G** coefficients. This is because the SYSLIN procedure writes the coefficients to the OUTEST= data set in the form

$$0 = \mathbf{H}\mathbf{y}_t + \mathbf{C}\mathbf{y}_t^L + \mathbf{B}\mathbf{x}_t$$

where $\mathbf{H} = -\mathbf{G}$.

See "Multipliers for Higher Order Lags" and [Example 24.2](#) later in this chapter for more information on building the EST= data set.

DATA= Data Set

The DATA= data set must contain all of the exogenous variables. Values for all of the exogenous variables are required for each observation for which predicted endogenous values are desired. To forecast past the end of the historical data, the DATA= data set should contain nonmissing values for all of the exogenous variables and missing values for the endogenous variables for the forecast periods, in addition to the historical data. (See [Example 24.1](#) for an illustration.)

In order for PROC SIMLIN to output residuals and compute statistics of fit, the DATA= data set must also contain the endogenous variables with nonmissing actual values for each observation for which residuals and statistics are to be computed.

If the system contains lags, initial values must be supplied for the lagged variables. This can be done by including either the lagged variables or the endogenous variables, or both, in the DATA= data set. If the lagged variables are not in the DATA= data set or if they have missing values in the early observations, PROC SIMLIN prints a warning and uses the endogenous variable values from the early observations to initialize the lags.

OUTEST= Data Set

The OUTEST= data set contains all the variables read from the EST= data set. The variables in the OUTEST= data set are as follows.

- the BY statement variables, if any
- `_TYPE_`, a character variable that identifies the type of observation
- `_DEPVAR_`, a character variable containing the name of the dependent variable for the observation
- the endogenous variables
- the lagged endogenous variables
- the exogenous variables
- INTERCEPT, a numeric variable containing the intercept values
- `_MODEL_`, a character variable containing the name of the equation
- `_SIGMA_`, a numeric variable containing the estimated error variance of the equation (output only if present in the EST= data set)

The observations read from the EST= data set that supply the structural coefficients are copied to the OUTEST= data set, except that the signs of endogenous coefficients are reversed. For these observations, the `_TYPE_` variable values are the same as in the EST= data set.

In addition, the OUTEST= data set contains observations with the following `_TYPE_` values:

REDUCED	the reduced form coefficients. The endogenous variables for this group of observations contain the inverse of the endogenous coefficient matrix \mathbf{G} . The lagged endogenous variables contain the matrix $\Pi_1 = \mathbf{G}^{-1}\mathbf{C}$. The exogenous variables contain the matrix $\Pi_2 = \mathbf{G}^{-1}\mathbf{B}$.
IMULT <i>i</i>	the interim multipliers, if the INTERIM= option is specified. There are <i>gn</i> observations for the interim multipliers, where <i>g</i> is the number of endogenous variables and <i>n</i> is the value of the INTERIM= <i>n</i> option. For these observations the <code>_TYPE_</code> variable has the value IMULT <i>i</i> , where the interim number <i>i</i> ranges from 1 to <i>n</i> . The exogenous variables in groups of <i>g</i> observations that have a <code>_TYPE_</code> value of IMULT <i>i</i> contain the matrix $\mathbf{D}^i \Pi_2$ of multipliers at interim <i>i</i> . The endogenous and lagged endogenous variables for this group of observations are set to missing.
TOTAL	the total multipliers, if the TOTAL option is specified. The exogenous variables in this group of observations contain the matrix $(\mathbf{I} - \mathbf{D})^{-1} \Pi_2$. The endogenous and lagged endogenous variables for this group of observations are set to missing.

OUT= Data Set

The OUT= data set normally contains all of the variables in the input DATA= data set, plus the variables named in the PREDICTED= and RESIDUAL= options in the OUTPUT statement.

You can use an ID statement to restrict the variables that are copied from the input data set. If an ID statement is used, the OUT= data set contains only the BY variables (if any), the ID variables, the endogenous and lagged endogenous variables (if any), the exogenous variables, plus the PREDICTED= and RESIDUAL= variables.

The OUT= data set contains an observation for each observation in the DATA= data set. When the actual value of an endogenous variable is missing in the DATA= data set, or when the DATA= data set does not contain the endogenous variable, the corresponding residual is missing.

Printed Output

Structural Form

The following items are printed as they are read from the EST= input data set. Structural zeros are printed as dots in the listing of these matrices.

1. Structural Coefficients for Endogenous Variables. This is the \mathbf{G} matrix, with *g* rows and *g* columns.
2. Structural Coefficients for Lagged Endogenous Variables. These coefficients make up the \mathbf{C} matrix, with *g* rows and *l* columns.

3. Structural Coefficients for Exogenous Variables. These coefficients make up the **B** matrix, with g rows and k columns.

Reduced Form

1. The reduced form coefficients are obtained by inverting **G** so that the endogenous variables can be directly expressed as functions of only lagged endogenous and exogenous variables.
2. Inverse Coefficient Matrix for Endogenous Variables. This is the inverse of the **G** matrix.
3. Reduced Form for Lagged Endogenous Variables. This is $\Pi_1 = \mathbf{G}^{-1}\mathbf{C}$, with g rows and l columns. Each value is a dynamic multiplier that shows how past values of lagged endogenous variables affect values of each of the endogenous variables.
4. Reduced Form for Exogenous Variables. This is $\Pi_2 = \mathbf{G}^{-1}\mathbf{B}$, with g rows and k columns. Its values are called *impact multipliers* because they show the immediate effect of each exogenous variable on the value of the endogenous variables.

Multipliers

Interim and total multipliers show the effect of a change in an exogenous variable over time.

1. Interim Multipliers. These are the interim multiplier matrices. They are formed by multiplying Π_2 by powers of **D**. The d th interim multiplier is $\mathbf{D}^d \Pi_2$. The interim multiplier of order d shows the effects of a change in the exogenous variables after d periods. Interim multipliers are only available if the maximum lag of the endogenous variables is 1.
2. Total Multipliers. This is the matrix of total multipliers, $\mathbf{T} = (\mathbf{I} - \mathbf{D})^{-1} \Pi_2$. This matrix shows the cumulative effect of changes in the exogenous variables. Total multipliers are only available if the maximum lag is one.

Statistics of Fit

If the DATA= option is used and the DATA= data set contains endogenous variables, PROC SIMLIN prints a statistics-of-fit report for the simulation. The statistics printed include the following. (Summations are over the observations for which both y_t and \hat{y}_t are nonmissing.)

1. the number of nonmissing errors. (Number of observations for which both y_t and \hat{y}_t are nonmissing.)
2. the mean error: $\frac{1}{n} \sum (y_t - \hat{y}_t)$
3. the mean percent error: $\frac{100}{n} \sum \frac{(y_t - \hat{y}_t)}{y_t}$
4. the mean absolute error: $\frac{1}{n} \sum |y_t - \hat{y}_t|$
5. the mean absolute percent error $\frac{100}{n} \sum \frac{|y_t - \hat{y}_t|}{y_t}$

6. the root mean square error: $\sqrt{\frac{1}{n} \sum (y_t - \hat{y}_t)^2}$
7. the root mean square percent error: $\sqrt{\frac{100}{n} \sum \left(\frac{y_t - \hat{y}_t}{y_t}\right)^2}$

ODS Table Names

PROC SIMLIN assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 24.2 ODS Tables Produced in PROC SIMLIN

ODS Table Name	Description	Option
Endogenous	Structural Coefficients for Endogenous Variables	default
LaggedEndogenous	Structural Coefficients for Lagged Endogenous Variables	default
Exogenous	Structural Coefficients for Exogenous Variables	default
InverseCoeff	Inverse Coefficient Matrix for Endogenous Variables	default
RedFormLagEndo	Reduced Form for Lagged Endogenous Variables	default

InterimMult	Interim Multipliers	INTERIM= option
TotalMult	Total Multipliers	TOTAL= option
FitStatistics	Fit statistics	default

Examples: SIMLIN Procedure

Example 24.1: Simulating Klein's Model I

In this example, the SIMLIN procedure simulates a model of the U.S. economy called Klein's Model I. The SAS data set KLEIN is used as input to the SYSLIN and SIMLIN procedures.

```
data klein;
```

```

input year c p w i x wp g t k wsum;
date=mdy(1,1,year);
format date year.;
y  = c + i + g - t;
yr = year - 1931;
klag = lag( k );
plag = lag( p );
xlag = lag( x );
if year >= 1921;
label c  ='consumption'
      p  ='profits'
      w  ='private wage bill'
      i  ='investment'
      k  ='capital stock'
      y  ='national income'
      x  ='private production'
      wsum='total wage bill'
      wp ='govt wage bill'
      g  ='govt demand'
      t  ='taxes'
      klag='capital stock lagged'
      plag='profits lagged'
      xlag='private product lagged'
      yr ='year-1931';
datalines;
1920      .  12.7      .      .  44.9      .      .      .  182.8      .
... more lines ...

```

First, the model is specified and estimated using the SYSLIN procedure, and the parameter estimates are written to an OUTEST= data set. The printed output produced by the SYSLIN procedure is not shown here; see [Example 27.1](#) in [Chapter 27](#) for the printed output of the PROC SYSLIN step.

```

Using the OUTEST= data set A produced by the SYSLIN procedure, the SIMLIN procedure can now compute the reduced form and simulate the model. The following statements perform the simulation.

```

title1 'Simulation of Klein''s Model I using SIMLIN';
proc simlin data=klein
    est=a type=3sls
    estprint
    total interim=2
    outest=b;
endogenous c p w i x wsum k y;
exogenous wp g t yr;
lagged klag k 1   plag p 1   xlag x 1;
id year;
output out=c p=chat phat what ihat xhat wsumhat khat yhat
        r=cres pres wres ires xres wsumres kres yres;
run;

```

The reduced form coefficients and multipliers are added to the information read from EST= data set A and written to the OUTEST= data set B. The predicted and residual values from the simulation are written to the OUT= data set C specified in the OUTPUT statement.

The SIMLIN procedure first prints the structural coefficient matrices read from the EST= data set, as shown in [Output 24.1.2](#) through [Output 24.1.4](#).

Output 24.1.2 SIMLIN Procedure Output – Endogenous Structural Coefficients

Simulation of Klein's Model I using SIMLIN				
The SIMLIN Procedure				
Structural Coefficients for Endogenous Variables				
Variable	c	p	w	i
c	1.0000	-0.1249	.	.
i	.	0.0131	.	1.0000
w	.	.	1.0000	.
x	-1.0000	.	.	-1.0000
y	-1.0000	.	.	-1.0000
p	.	1.0000	1.0000	.
k	.	.	.	-1.0000
wsum	.	.	-1.0000	.

Structural Coefficients for Endogenous Variables				
Variable	x	wsum	k	y
c	.	-0.7901	.	.
i
w	-0.4005	.	.	.
x	1.0000	.	.	.
y	.	.	.	1.0000
p	-1.0000	.	.	.
k	.	.	1.0000	.
wsum	.	1.0000	.	.

Output 24.1.3 SIMLIN Procedure Output – Lagged Endogenous Structural Coefficients

Structural Coefficients for Lagged Endogenous Variables			
Variable	klag	plag	xlag
c	.	0.1631	.
i	-0.1948	0.7557	.
w	.	.	0.1813
x	.	.	.
y	.	.	.
p	.	.	.
k	1.0000	.	.
wsum	.	.	.

Output 24.1.4 SIMLIN Procedure Output – Exogenous Structural Coefficients

Structural Coefficients for Exogenous Variables					
Variable	wp	g	t	yr	Intercept
c	16.4408
i	28.1778
w	.	.	.	0.1497	1.7972
x	.	1.0000	.	.	0
y	.	1.0000	-1.0000	.	0
p	.	.	-1.0000	.	0
k	0
wsum	1.0000	.	.	.	0

The SIMLIN procedure then prints the inverse of the endogenous variables coefficient matrix, as shown in [Output 24.1.5](#).

Output 24.1.5 SIMLIN Procedure Output – Inverse Coefficient Matrix

Inverse Coefficient Matrix for Endogenous Variables				
Variable	c	i	w	x
c	1.6347	0.6347	1.0957	0.6347
p	0.9724	0.9724	-0.3405	0.9724
w	0.6496	0.6496	1.4406	0.6496
i	-0.0127	0.9873	0.004453	-0.0127
x	1.6219	1.6219	1.1001	1.6219
wsum	0.6496	0.6496	1.4406	0.6496
k	-0.0127	0.9873	0.004453	-0.0127
y	1.6219	1.6219	1.1001	0.6219

Inverse Coefficient Matrix for Endogenous Variables				
Variable	y	p	k	wsum
c	0	0.1959	0	1.2915
p	0	1.1087	0	0.7682
w	0	0.0726	0	0.5132
i	0	-0.0145	0	-0.0100
x	0	0.1814	0	1.2815
wsum	0	0.0726	0	1.5132
k	0	-0.0145	1.0000	-0.0100
y	1.0000	0.1814	0	1.2815

The SIMLIN procedure next prints the reduced form coefficient matrices, as shown in [Output 24.1.6](#).

Output 24.1.6 SIMLIN Procedure Output – Reduced Form Coefficients

Reduced Form for Lagged Endogenous Variables			
Variable	k _{lag}	p _{lag}	x _{lag}
c	-0.1237	0.7463	0.1986
p	-0.1895	0.8935	-0.0617

The actual and predicted values for the variable C are plotted in [Output 24.1.11](#).

```

title2 'Plots of Simulation Results';
proc sgplot data=c;
  scatter x=year y=c;
  series x=year y=chat / markers markerattrs=(symbol=plus);
  refline 1941.5 / axis=x;
run;

```

Output 24.1.11 Plot of Actual and Predicted Consumption

Example 24.2: Multipliers for a Third-Order System

This example shows how to fit and simulate a single equation dynamic model with third-order lags. It then shows how to convert the third-order equation into a three equation system with only first-order lags, so that the SIMLIN procedure can compute multipliers. (See the section "Multipliers for Higher Order Lags" earlier in this chapter for more information.)

The input data set TEST is created from simulated data. A partial listing of the data set TEST produced by PROC PRINT is shown in [Output 24.2.1](#).

Output 24.2.1 Partial Listing of Input Data Set

Simulate Equation with Third-Order Lags Listing of Simulated Input Data

Overview: SPECTRA Procedure

The SPECTRA procedure performs spectral and cross-spectral analysis of time series. You can use spectral analysis techniques to look for periodicities or cyclical patterns in data.

The SPECTRA procedure produces estimates of the spectral and cross-spectral densities of a multivariate time series. Estimates of the spectral and cross-spectral densities of a multivariate time series are produced using a finite Fourier transform to obtain periodograms and cross-periodograms.

The periodogram ordinates are smoothed by a moving average to produce estimated spectral and cross-spectral densities. PROC SPECTRA can also test whether or not the data are white noise.

PROC SPECTRA uses the finite Fourier transform to decompose data series into a sum of sine and cosine waves of different amplitudes and wavelengths. The Fourier transform decomposition of the series x_t is

$$x_t = \frac{a_0}{2} + \sum_{k=1}^m [a_k \cos(\omega_k t) + b_k \sin(\omega_k t)]$$

where

t	is the time subscript, $t = 1, 2, \dots, n$
x_t	are the equally spaced time series data
n	is the number of observations in the time series
m	is the number of frequencies in the Fourier decomposition: $m = \frac{n}{2}$ if n is even; $m = \frac{n-1}{2}$ if n is odd
a_0	is the mean term: $a_0 = 2\bar{x}$
a_k	are the cosine coefficients
b_k	are the sine coefficients
ω_k	are the Fourier frequencies: $\omega_k = \frac{2\pi k}{n}$

Functions of the Fourier coefficients a_k and b_k can be plotted against frequency or against wave length to form *periodograms*. The amplitude periodogram J_k is defined as follows:

$$J_k = \frac{n}{2}(a_k^2 + b_k^2)$$

Several definitions of the term periodogram are used in the spectral analysis literature. The following discussion refers to the J_k sequence as the periodogram.

The periodogram can be interpreted as the contribution of the k th harmonic ω_k to the total sum of squares (in an analysis of variance sense) in the decomposition of the process into two-degree-of-freedom components for each of the m frequencies. When n is even, $\sin(\omega_{\frac{n}{2}})$ is zero, and thus the last periodogram value is a one-degree-of-freedom component.

The periodogram is a volatile and inconsistent estimator of the spectrum. The spectral density estimate is produced by smoothing the periodogram. Smoothing reduces the variance of the estimator but introduces a bias. The weight function used for the smoothing process, $W()$, often called the kernel or spectral window, is specified with the WEIGHTS statement. It is related to another weight function, $w()$, the lag window, that is used in other methods to taper the correlogram rather than to smooth the periodogram. Many specific weighting functions have been suggested in the literature (Fuller 1976, Jenkins and Watts 1968, Priestly 1981). Table 25.3 later in this chapter gives the relevant formulas when the WEIGHTS statement is used.

Letting i represent the imaginary unit $\sqrt{-1}$, the cross-periodogram is defined as follows:

$$J_k^{xy} = \frac{n}{2}(a_k^x a_k^y + b_k^x b_k^y) + i \frac{n}{2}(a_k^x b_k^y - b_k^x a_k^y)$$

The cross-spectral density estimate is produced by smoothing the cross-periodogram in the same way as the periodograms are smoothed using the spectral window specified by the WEIGHTS statement.

The SPECTRA procedure creates an output SAS data set whose variables contain values of the periodograms, cross-periodograms, estimates of spectral densities, and estimates of cross-spectral densities. The form of the output data set is described in the section “OUT= Data Set” on page 1700.

Getting Started: SPECTRA Procedure

To use the SPECTRA procedure, specify the input and output data sets and options for the analysis you want in the PROC SPECTRA statement, and list the variables to analyze in the VAR statement. The procedure produces no printed output unless the WHITETEST option is specified in the PROC SPECTRA statement. The periodogram, spectral density, and other results are written to the OUT= data set, depending on the options used.

For example, to compute the Fourier transform of a variable X in a data set A, use the following statements:

```
proc spectra data=a out=b coef;
  var x;
run;
```

This PROC SPECTRA step writes the Fourier coefficients a_k and b_k to the variables COS_01 and SIN_01 in the output data set B.

When a WEIGHTS statement is specified, the periodogram is smoothed by a weighted moving average to produce an estimate of the spectral density of the series. The following statements write a spectral density estimate for X to the variable S_01 in the output data set B.

```
proc spectra data=a out=b s;
  var x;
  weights 1 2 3 4 3 2 1;
run;
```

When the VAR statement specifies more than one variable, you can perform cross-spectral analysis by specifying the CROSS option in the PROC SPECTRA statement. The CROSS option by itself produces the cross-periodograms for all two-way combinations of the variables listed in the VAR statement. For example, the following statements write the real and imaginary parts of the cross-periodogram of X and Y to the variables RP_01_02 and IP_01_02 in the output data set B.

```
proc spectra data=a out=b cross;
  var x y;
run;
```

To produce cross-spectral density estimates, specify both the CROSS option and the S option. The cross-periodogram is smoothed using the weights specified by the WEIGHTS statement in the same way as the spectral density. The squared coherency and phase estimates of the cross-spectrum are computed when the K and PH options are used.

The following example computes cross-spectral density estimates for the variables X and Y.

```
proc spectra data=a out=b cross s;
  var x y;
  weights 1 2 3 4 3 2 1;
run;
```

The real part and imaginary part of the cross-spectral density estimates are written to the variables CS_01_02 and QS_01_02, respectively.

Syntax: SPECTRA Procedure

The following statements are used with the SPECTRA procedure:

```
PROC SPECTRA options ;
  BY variables ;
  VAR variables ;
  WEIGHTS < weights > < kernel > ;
```

Functional Summary

Table 25.1 summarizes the statements and options that control the SPECTRA procedure.

Table 25.1 SPECTRA Functional Summary

Description	Statement	Option
Statements		
specify BY-group processing	BY	
specify the variables to be analyzed	VAR	
specify weights for spectral density estimates	WEIGHTS	
Data Set Options		
specify the input data set	PROC SPECTRA	DATA=
specify the output data set	PROC SPECTRA	OUT=
Output Control Options		
output the amplitudes of the cross-spectrum	PROC SPECTRA	A
output the Fourier coefficients	PROC SPECTRA	COEF

Table 25.1 *continued*

Description	Statement	Option
output the periodogram	PROC SPECTRA	P
output the spectral density estimates	PROC SPECTRA	S
output cross-spectral analysis results	PROC SPECTRA	CROSS
output squared coherency of the cross-spectrum	PROC SPECTRA	K
output the phase of the cross-spectrum	PROC SPECTRA	PH

Other Options		
subtract the series mean	PROC SPECTRA	ADJMEAN
specify an alternate quadrature spectrum estimate	PROC SPECTRA	ALTW
request tests for white noise	PROC SPECTRA	WHITESTEST

PROC SPECTRA Statement

PROC SPECTRA *options* ;

The following options can be used in the PROC SPECTRA statement:

A

outputs the amplitude variables ($A_{nn} \text{ } _{mm}$) of the cross-spectrum.

ADJMEAN

CENTER

subtracts the series mean before performing the Fourier decomposition. This sets the first periodogram ordinate to 0 rather than $2n$ times the squared mean. This option is commonly used when the periodograms are to be plotted to prevent a large first periodogram ordinate from distorting the scale of the plot.

ALTW

specifies that the quadrature spectrum estimate is computed at the boundaries in the same way as the spectral density estimate and the cospectrum estimate are computed.

COEF

outputs the Fourier cosine and sine coefficients of each series.

CROSS

is used with the P and S options to output cross-periodograms and cross-spectral densities when more than one variable is listed in the VAR statement.

DATA=SAS-data-set

names the SAS data set that contains the input data. If the DATA= option is omitted, the most recently created SAS data set is used.

K

outputs the squared coherency variables (K_{nn_mm}) of the cross-spectrum. The K_{nn_mm} variables are identically 1 unless weights are given in the WEIGHTS statement and the S option is specified.

OUT=SAS-data-set

names the output data set created by PROC SPECTRA to store the results. If the OUT= option is omitted, the output data set is named by using the $DATA_n$ convention.

P

outputs the periodogram variables. The variables are named P_{nn} , where nn is an index of the original variable with which the periodogram variable is associated. When both the P and CROSS options are specified, the cross-periodogram variables RP_{nn_mm} and IP_{nn_mm} are also output.

PH

outputs the phase variables (PH_{nn_mm}) of the cross-spectrum.

S

outputs the spectral density estimates. The variables are named S_{nn} , where nn is an index of the original variable with which the estimate variable is associated. When both the S and CROSS options are specified, the cross-spectral variables CS_{nn_mm} and QS_{nn_mm} are also output.

WHITETEST

prints two tests of the hypothesis that the data are white noise. See the section “[White Noise Test](#)” on page 1699 for details.

Note that the CROSS, A, K, and PH options are meaningful only if more than one variable is listed in the VAR statement.

BY Statement

BY *variables* ;

A BY statement can be used with PROC SPECTRA to obtain separate analyses for groups of observations defined by the BY variables.

VAR Statement

VAR *variables* ;

The VAR statement specifies one or more numeric variables that contain the time series to analyze. The order of the variables in the VAR statement list determines the index, m , used to name the output variables. The VAR statement is required.

WEIGHTS Statement

WEIGHTS *weight-constants | kernel-specification* ;

The WEIGHTS statement specifies the relative weights used in the moving average applied to the periodogram ordinates to form the spectral density estimates. A WEIGHTS statement must be used to produce smoothed spectral density estimates. You can specify the relative weights in two ways: you can specify them explicitly as explained in the section “Using Weight Constants Specification” on page 1695, or you can specify them implicitly by using the kernel specification as explained in the section “Using Kernel Specifications” on page 1695. If the WEIGHTS statement is not used, only the periodogram is produced.

Using Weight Constants Specification

Any number of weighting constants can be specified. The constants should be positive and symmetric about the middle weight. The middle constant (or the constant to the right of the middle if an even number of weight constants are specified) is the relative weight of the current periodogram ordinate. The constant immediately following the middle one is the relative weight of the next periodogram ordinate, and so on. The actual weights used in the smoothing process are the weights specified in the WEIGHTS statement scaled so that they sum to $\frac{1}{4\pi}$.

The moving average reflects at each end of the periodogram. The first periodogram ordinate is not used; the second periodogram ordinate is used in its place.

For example, a simple triangular weighting can be specified using the following WEIGHTS statement:

```
weights 1 2 3 2 1;
```

Using Kernel Specifications

You can specify five different kernels in the WEIGHTS statement. The syntax for the statement is

WEIGHTS [PARZEN][BART][TUKEY][TRUNCAT][QS] [c e] ;

where $c \geq 0$ and $e \geq 0$ are used to compute the bandwidth parameter as

$$l(q) = cq^e$$

and q is the number of periodogram ordinates +1:

$$q = \text{floor}(n/2) + 1$$

To specify the bandwidth explicitly, set $c =$ to the desired bandwidth and $e = 0$.

For example, a Parzen kernel can be specified using the following WEIGHTS statement:

```
weights parzen 0.5 0;
```

For details, see the section “Kernels” on page 1697.

Details: SPECTRA Procedure

Input Data

Observations in the data set analyzed by the SPECTRA procedure should form ordered, equally spaced time series. No more than 99 variables can be included in the analysis.

Data are often detrended before analysis by the SPECTRA procedure. This can be done by using the residuals output by a SAS regression procedure. Optionally, the data can be centered using the ADJMEAN option in the PROC SPECTRA statement, since the zero periodogram ordinate corresponding to the mean is of little interest from the point of view of spectral analysis.

Missing Values

Missing values are excluded from the analysis by the SPECTRA procedure. If the SPECTRA procedure encounters missing values for any variable listed in the VAR statement, the procedure determines the longest contiguous span of data that has no missing values for the variables listed in the VAR statement and uses that span for the analysis.

Computational Method

If the number of observations n factors into prime integers that are less than or equal to 23, and the product of the square-free factors of n is less than 210, then PROC SPECTRA uses the fast Fourier transform developed by Cooley and Tukey and implemented by Singleton (1969). If n cannot be factored in this way, then PROC SPECTRA uses a Chirp-Z algorithm similar to that proposed by Monro and Branch (1976). To reduce memory requirements, when n is small, the Fourier coefficients are computed directly using the defining formulas.

Kernels

Kernels are used to smooth the periodogram by using a weighted moving average of nearby points. A smoothed periodogram is defined by the following equation.

$$\hat{J}_i(l(q)) = \sum_{\tau=-l(q)}^{l(q)} w\left(\frac{\tau}{l(q)}\right) \tilde{J}_{i+\tau}$$

where $w(x)$ is the kernel or weight function. At the endpoints, the moving average is computed cyclically; that is,

$$\tilde{J}_{i+\tau} = \begin{cases} J_{i+\tau} & 0 \leq i + \tau \leq q \\ J_{-(i+\tau)} & i + \tau < 0 \\ J_{q-(i+\tau)} & i + \tau > q \end{cases}$$

The SPECTRA procedure supports the following kernels. They are listed with their default bandwidth functions.

Bartlett: KERNEL BART

$$w(x) = \begin{cases} 1 - |x| & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

$$l(q) = \frac{1}{2}q^{1/3}$$

Parzen: KERNEL PARZEN

$$w(x) = \begin{cases} 1 - 6|x|^2 + 6|x|^3 & 0 \leq |x| \leq \frac{1}{2} \\ 2(1 - |x|)^3 & \frac{1}{2} \leq |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

$$l(q) = q^{1/5}$$

Quadratic spectral: KERNEL QS

$$w(x) = \frac{25}{12\pi^2 x^2} \left(\frac{\sin(6\pi x/5)}{6\pi x/5} - \cos(6\pi x/5) \right)$$

$$l(q) = \frac{1}{2}q^{1/5}$$

Tukey-Hanning: KERNEL TUKEY

$$w(x) = \begin{cases} (1 + \cos(\pi x))/2 & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

$$l(q) = \frac{2}{3}q^{1/5}$$

Truncated: KERNEL TRUNCAT

$$w(x) = \begin{cases} 1 & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

$$l(q) = \frac{1}{4}q^{1/5}$$

A summary of the default values of the bandwidth parameters, c and e , associated with the kernel smoothers in PROC SPECTRA are listed below in [Table 25.2](#):

Table 25.2 Bandwidth Parameters

Kernel	c	e
Bartlett	1/2	1/3
Parzen	1	1/5
quadratic	1/2	1/5
Tukey-Hanning	2/3	1/5
truncated	1/4	1/5

Figure 25.1 Kernels for Smoothing

See Andrews (1991) for details about the properties of these kernels.

White Noise Test

PROC SPECTRA prints two test statistics for white noise when the WHITETEST option is specified: Fisher's Kappa (Davis 1941, Fuller 1976) and Bartlett's Kolmogorov-Smirnov statistic (Bartlett 1966, Fuller 1976, Durbin 1967).

If the time series is a sequence of independent random variables with mean 0 and variance σ^2 , then the periodogram, J_k , will have the same expected value for all k . For a time series with nonzero autocorrelation, each ordinate of the periodogram, J_k , will have different expected values. The Fisher's Kappa statistic tests whether the largest J_k can be considered different from the mean of the J_k . Critical values for the Fisher's Kappa test can be found in Fuller 1976.

The Kolmogorov-Smirnov statistic reported by PROC SPECTRA has the same asymptotic distribution as Bartlett's test (Durbin 1967). The Kolmogorov-Smirnov statistic compares the normalized cumulative periodogram with the cumulative distribution function of a uniform(0,1) random variable. The normalized cumulative periodogram, F_j , of the series is

$$F_j = \frac{\sum_{k=1}^j J_k}{\sum_{k=1}^m J_k}, j = 1, 2, \dots, m-1$$

where $m = \frac{n}{2}$ if n is even or $m = \frac{n-1}{2}$ if n is odd. The test statistic is the maximum absolute difference of the normalized cumulative periodogram and the uniform cumulative distribution function. Approximate p -values for Bartlett's Kolmogorov-Smirnov test statistics are provided with the test statistics. Small p -values cause you to reject the null-hypothesis that the series is white noise.

Transforming Frequencies

The variable FREQ in the data set created by the SPECTRA procedure ranges from 0 to π . Sometimes it is preferable to express frequencies in cycles per observation period, which is equal to $\frac{2}{\pi}$ FREQ.

To express frequencies in cycles per unit time (for example, in cycles per year), multiply FREQ by $\frac{d}{2\pi}$, where d is the number of observations per unit of time. For example, for monthly data, if the desired time unit is years then d is 12. The period of the cycle is $\frac{2\pi}{d \times \text{FREQ}}$, which ranges from $\frac{2}{d}$ to infinity.

OUT= Data Set

The OUT= data set contains $\frac{n}{2} + 1$ observations, if n is even, or $\frac{n+1}{2}$ observations, if n is odd, where n is the number of observations in the time series or the span of data being analyzed if missing values are present in the data. See the section “Missing Values” on page 1696 for details.

The variables in the new data set are named according to the following conventions. Each variable to be analyzed is associated with an index. The first variable listed in the VAR statement is indexed as 01, the second variable as 02, and so on. Output variables are named by combining indexes with prefixes. The prefix always identifies the nature of the new variable, and the indices identify the original variables from which the statistics were obtained.

Variables that contain spectral analysis results have names that consist of a prefix, an underscore, and the index of the variable analyzed. For example, the variable S_01 contains spectral density estimates for the first variable in the VAR statement. Variables that contain cross-spectral analysis results have names that consist of a prefix, an underscore, the index of the first variable, another underscore, and the index of the second variable. For example, the variable A_01_02 contains the amplitude of the cross-spectral density estimate for the first and second variables in the VAR statement.

Table 25.3 shows the formulas and naming conventions used for the variables in the OUT= data set. Let X be variable number nn in the VAR statement list and let Y be variable number mm in the VAR statement list. Table 25.3 shows the output variables that contain the results of the spectral and cross-spectral analysis of X and Y .

In Table 25.3 the following notation is used. Let W_j be the vector of $2p + 1$ smoothing weights given by the WEIGHTS statement, normalized to sum to $\frac{1}{4\pi}$. Note that the weights are either explicitly provided using the constant specification or are implicitly determined by the kernel specification in the WEIGHTS statement.

The subscript of W_j runs from W_{-p} to W_p , so that W_0 is the middle weight in the list. Let $\omega_k = \frac{2\pi k}{n}$, where $k = 0, 1, \dots, \text{floor}(\frac{n}{2})$.

Table 25.3 Variables Created by PROC SPECTRA

Variable	Description
FREQ	frequency in radians from 0 to π (Note: Cycles per observation is $\frac{\text{FREQ}}{2\pi}$.)
PERIOD	period or wavelength: $\frac{2\pi}{\text{FREQ}}$ (Note: PERIOD is missing for FREQ=0.)
COS_nn	cosine transform of X: $a_k^x = \frac{2}{n} \sum_{t=1}^n X_t \cos(\omega_k(t-1))$
SIN_nn	sine transform of X: $b_k^x = \frac{2}{n} \sum_{t=1}^n X_t \sin(\omega_k(t-1))$
P_nn	periodogram of X: $J_k^x = \frac{n}{2} [(a_k^x)^2 + (b_k^x)^2]$
S_nm	spectral density estimate of X: $F_k^x = \sum_{j=-p}^p W_j J_{k+j}^x$ (except across endpoints)
RP_nm_mm	real part of cross-periodogram X and Y: $\text{real}(J_k^{xy}) = \frac{n}{2} (a_k^x a_k^y + b_k^x b_k^y)$
IP_nm_mm	imaginary part of cross-periodogram of X and Y: $\text{imag}(J_k^{xy}) = \frac{n}{2} (a_k^x b_k^y - b_k^x a_k^y)$
CS_nm_mm	cospectrum estimate (real part of cross-spectrum) of X and Y: $C_k^{xy} = \sum_{j=-p}^p W_j \text{real}(J_{k+j}^{xy})$ (except across endpoints)
QS_nm_mm	quadrature spectrum estimate (imaginary part of cross-spectrum) of X and Y: $Q_k^{xy} = \sum_{j=-p}^p W_j \text{imag}(J_{k+j}^{xy})$ (except across endpoints)
A_nm_mm	amplitude (modulus) of cross-spectrum of X and Y: $A_k^{xy} = \sqrt{(C_k^{xy})^2 + (Q_k^{xy})^2}$
K_nm_mm	coherency squared of X and Y: $K_k^{xy} = (A_k^{xy})^2 / (F_k^x F_k^y)$
PH_nm_mm	phase spectrum in radians of X and Y: $\Phi_k^{xy} = \arctan(Q_k^{xy} / C_k^{xy})$

Printed Output

By default PROC SPECTRA produces no printed output.

When the WHITETEST option is specified, the SPECTRA procedure prints the following statistics for each variable in the VAR statement:

1. the name of the variable
2. $M-1$, the number of two-degree-of-freedom periodogram ordinates used in the test
3. $\text{MAX}(P(*))$, the maximum periodogram ordinate
4. $\text{SUM}(P(*))$, the sum of the periodogram ordinates
5. Fisher's Kappa statistic
6. Bartlett's Kolmogorov-Smirnov test statistic
7. Approximate p -value for Bartlett's Kolmogorov-Smirnov test statistic

See the section “White Noise Test” on page 1699 for details.

ODS Table Names: SPECTRA procedure

PROC SPECTRA assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 25.4 ODS Tables Produced in PROC SPECTRA

ODS Table Name	Description	Option
WhiteNoiseTest	white noise test	WHITETEST
Kappa	Fishers Kappa statistic	WHITETEST
Bartlett	Bartletts Kolmogorov-Smirnov statistic	WHITETEST

Examples: SPECTRA Procedure

Example 25.1: Spectral Analysis of Sunspot Activity

This example analyzes Wolfer's sunspot data (Anderson 1971). The following statements read and plot the data.

```
title "Wolfer's Sunspot Data";
data sunspot;
  input year wolfer @@;
datalines;

  ... more lines ...

proc sgplot data=sunspot;
  series x=year y=wolfer / markers markerattrs=(symbol=circlefilled);
  xaxis values=(1740 to 1930 by 10);
  yaxis values=(0 to 1600 by 200);
run;
```

The plot of the sunspot series is shown in [Output 25.1.1](#).

Output 25.1.1 Plot of Original Sunspot Data

The spectral analysis of the sunspot series is performed by the following statements:

```
proc spectra data=sunspot out=b p s adjmean whitetest;
  var wolfer;
  weights 1 2 3 4 3 2 1;
run;
proc print data=b(obs=12);
run;
```

The PROC SPECTRA statement specifies the P and S options to write the periodogram and spectral density estimates to the OUT= data set B. The WEIGHTS statement specifies a triangular spectral window for smoothing the periodogram to produce the spectral density estimate. The ADJMEAN option zeros the frequency 0 value and avoids the need to exclude that observation from the plots. The WHITETEST option prints tests for white noise.

The Fisher's Kappa test statistic of 16.070 is larger than the 5% critical value of 7.2, so the null hypothesis that the sunspot series is white noise is rejected (see the table of critical values in Fuller (1976)).

The Bartlett's Kolmogorov-Smirnov statistic is 0.6501, and its approximate p -value is < 0.0001 . The small p -value associated with this test leads to the rejection of the null hypothesis that the spectrum represents white noise.

The printed output produced by PROC SPECTRA is shown in [Output 25.1.2](#). The output data set B created by PROC SPECTRA is shown in part in [Output 25.1.3](#).

Output 25.1.2 White Noise Test Results

```

Approximate P-Value           <.0001
    
```

Output 25.1.3 First 12 Observations of the OUT= Data Set

Wolfer's Sunspot Data				
Obs	FREQ	PERIOD	P_01	S_01
1	0.00000	.	0.00	59327.52
2	0.03570	176.000	3178.15	61757.98
3	0.07140	88.000	2435433.22	69528.68
4	0.10710	58.667	1077495.76	66087.57
5	0.14280	44.000	491850.36	53352.02
6	0.17850	35.200	2581.12	36678.14
7	0.21420	29.333	181163.15	20604.52
8	0.24990	25.143	283057.60	15132.81
9	0.28560	22.000	188672.97	13265.89
10	0.32130	19.556	122673.94	14953.32
11	0.35700	17.600	58532.93	16402.84
12	0.39270	16.000	213405.16	18562.13

The following statements plot the periodogram and spectral density estimate by the frequency and period.

```

proc sgplot data=b;
  series x=freq y=p_01 / markers markerattrs=(symbol=circlefilled);
run;

proc sgplot data=b;
  series x=period y=p_01 / markers markerattrs=(symbol=circlefilled);
run;

proc sgplot data=b;
  series x=freq y=s_01 / markers markerattrs=(symbol=circlefilled);
run;

proc sgplot data=b;
  series x=period y=s_01 / markers markerattrs=(symbol=circlefilled);
run;

```

The periodogram is plotted against the frequency in [Output 25.1.4](#) and plotted against the period in [Output 25.1.5](#). The spectral density estimate is plotted against the frequency in [Output 25.1.6](#) and plotted against the period in [Output 25.1.7](#).

Output 25.1.4 Plot of Periodogram by Frequency

Output 25.1.5 Plot of Periodogram by Period

Output 25.1.6 Plot of Spectral Density Estimate by Frequency

Output 25.1.7 Plot of Spectral Density Estimate by Period

Since PERIOD is the reciprocal of frequency, the plot axis for PERIOD is stretched for low frequencies and compressed at high frequencies. One way to correct for this is to use a WHERE statement to restrict the plots and exclude the low frequency components. The following statements plot the spectral density for periods less than 50.

```
proc sgplot data=b;
  where period < 50;
  series x=period y=s_01 / markers markerattrs=(symbol=circlefilled);
  refline 11 / axis=x;
run;
title;
```

The spectral analysis of the sunspot series confirms a strong 11-year cycle of sunspot activity. The plot makes this clear by drawing a reference line at the 11 year period, which highlights the position of the main peak in the spectral density.

Output 25.1.8 shows the plot. Contrast Output 25.1.8 with Output 25.1.7.

Output 25.1.8 Plot of Spectral Density Estimate by Period to 50 Years

Example 25.2: Cross-Spectral Analysis

This example uses simulated data to show cross-spectral analysis for two variables X and Y. X is generated by an AR(1) process; Y is generated as white noise plus an input from X lagged 2 periods. All output options are specified in the PROC SPECTRA statement. PROC CONTENTS shows the contents of the OUT= data set.

```

data a;
  x1 = 0; x11 = 0;
  do i = - 10 to 100;
    x = .4 * x1 + rannor(123);
    y = .5 * x11 + rannor(123);
    if i > 0 then output;
    x11 = x1; x1 = x;
  end;
run;

```

```

proc spectra data=a out=b cross coef a k p ph s;
  var x y;
  weights 1 1.5 2 4 8 9 8 4 2 1.5 1;
run;

proc contents data=b position;
run;

```

The PROC CONTENTS report for the output data set B is shown in [Output 25.2.1](#).

Output 25.2.1 Contents of PROC SPECTRA OUT= Data Set

Overview: STATESPACE Procedure

The STATESPACE procedure uses the state space model to analyze and forecast multivariate time series. The STATESPACE procedure is appropriate for jointly forecasting several related time series that have dynamic interactions. By taking into account the autocorrelations among all the variables in a set, the STATESPACE procedure can give better forecasts than methods that model each series separately.

By default, the STATESPACE procedure automatically selects a state space model appropriate for the time series, making the procedure a good tool for automatic forecasting of multivariate time series. Alternatively, you can specify the state space model by giving the form of the state vector and the state transition and innovation matrices.

The methods used by the STATESPACE procedure assume that the time series are jointly stationary. Nonstationary series must be made stationary by some preliminary transformation, usually by differencing. The STATESPACE procedure enables you to specify differencing of the input data. When differencing is specified, the STATESPACE procedure automatically integrates forecasts of the differenced series to produce forecasts of the original series.

The State Space Model

The *state space model* represents a multivariate time series through auxiliary variables, some of which might not be directly observable. These auxiliary variables are called the *state vector*. The state vector summarizes all the information from the present and past values of the time series that is relevant to the prediction of future values of the series. The observed time series are expressed as linear combinations of the state variables. The state space model is also called a Markovian representation, or a canonical representation, of a multivariate time series process. The state space approach to modeling a multivariate stationary time series is summarized in Akaike (1976).

The state space form encompasses a very rich class of models. Any Gaussian multivariate stationary time series can be written in a state space form, provided that the dimension of the predictor space is finite. In particular, any autoregressive moving average (ARMA) process has a state space representation and, conversely, any state space process can be expressed in an ARMA form (Akaike 1974). More details on the relation of the state space and ARMA forms are given in the section “Relation of ARMA and State Space Forms” on page 1747.

Let \mathbf{x}_t be the $r \times 1$ vector of observed variables, after differencing (if differencing is specified) and subtracting the sample mean. Let \mathbf{z}_t be the state vector of dimension s , $s \geq r$, where the first r components of \mathbf{z}_t consist of \mathbf{x}_t . Let the notation $\mathbf{x}_{t+k|t}$ represent the conditional expectation (or prediction) of \mathbf{x}_{t+k} based on the information available at time t . Then the last $s - r$ elements of \mathbf{z}_t consist of elements of $\mathbf{x}_{t+k|t}$, where $k > 0$ is specified or determined automatically by the procedure.

There are various forms of the state space model in use. The form of the state space model used by the STATESPACE procedure is based on Akaike (1976). The model is defined by the following *state*

transition equation :

$$\mathbf{z}_{t+1} = \mathbf{F}\mathbf{z}_t + \mathbf{G}\mathbf{e}_{t+1}$$

In the state transition equation, the $s \times s$ coefficient matrix \mathbf{F} is called the *transition matrix*; it determines the dynamic properties of the model.

The $s \times r$ coefficient matrix \mathbf{G} is called the *input matrix*; it determines the variance structure of the transition equation. For model identification, the first r rows and columns of \mathbf{G} are set to an $r \times r$ identity matrix.

The input vector \mathbf{e}_t is a sequence of independent normally distributed random vectors of dimension r with mean $\mathbf{0}$ and covariance matrix Σ_{ee} . The random error \mathbf{e}_t is sometimes called the innovation vector or shock vector.

In addition to the state transition equation, state space models usually include a *measurement equation* or *observation equation* that gives the observed values \mathbf{x}_t as a function of the state vector \mathbf{z}_t . However, since PROC STATESPACE always includes the observed values \mathbf{x}_t in the state vector \mathbf{z}_t , the measurement equation in this case merely represents the extraction of the first r components of the state vector.

The measurement equation used by the STATESPACE procedure is

$$\mathbf{x}_t = [\mathbf{I}_r \mathbf{0}]\mathbf{z}_t$$

where \mathbf{I}_r is an $r \times r$ identity matrix. In practice, PROC STATESPACE performs the extraction of \mathbf{x}_t from \mathbf{z}_t without reference to an explicit measurement equation.

In summary:

\mathbf{x}_t	is an observation vector of dimension r .
\mathbf{z}_t	is a state vector of dimension s , whose first r elements are \mathbf{x}_t and whose last $s - r$ elements are conditional prediction of future \mathbf{x}_t .
\mathbf{F}	is an $s \times s$ transition matrix.
\mathbf{G}	is an $s \times r$ input matrix, with the identity matrix \mathbf{I}_r forming the first r rows and columns.
\mathbf{e}_t	is a sequence of independent normally distributed random vectors of dimension r with mean $\mathbf{0}$ and covariance matrix Σ_{ee} .

How PROC STATESPACE Works

The design of the STATESPACE procedure closely follows the modeling strategy proposed by Akaike (1976). This strategy employs canonical correlation analysis for the automatic identification of the state space model.

Following Akaike (1976), the procedure first fits a sequence of unrestricted vector autoregressive (VAR) models and computes Akaike's information criterion (AIC) for each model. The vector

autoregressive models are estimated using the sample autocovariance matrices and the Yule-Walker equations. The order of the VAR model that produces the smallest Akaike information criterion is chosen as the order (number of lags into the past) to use in the canonical correlation analysis.

The elements of the state vector are then determined via a sequence of canonical correlation analyses of the sample autocovariance matrices through the selected order. This analysis computes the sample canonical correlations of the past with an increasing number of steps into the future. Variables that yield significant correlations are added to the state vector; those that yield insignificant correlations are excluded from further consideration. The importance of the correlation is judged on the basis of another information criterion proposed by Akaike. See the section “[Canonical Correlation Analysis Options](#)” on page 1731 for details. If you specify the state vector explicitly, these model identification steps are omitted.

After the state vector is determined, the state space model is fit to the data. The free parameters in the F , G , and Σ_{ee} matrices are estimated by approximate maximum likelihood. By default, the F and G matrices are unrestricted, except for identifiability requirements. Optionally, conditional least squares estimates can be computed. You can impose restrictions on elements of the F and G matrices.

After the parameters are estimated, the Kalman filtering technique is used to produce forecasts from the fitted state space model. If differencing was specified, the forecasts are integrated to produce forecasts of the original input variables.

Getting Started: STATESPACE Procedure

The following introductory example uses simulated data for two variables X and Y. The following statements generate the X and Y series.

```
data in;
  x=10;  y=40;
  x1=0;  y1=0;
  a1=0;  b1=0;
  iseed=123;
  do t=-100 to 200;
    a=rannor(iseed);
    b=rannor(iseed);
    dx = 0.5*x1 + 0.3*y1 + a - 0.2*a1 - 0.1*b1;
    dy = 0.3*x1 + 0.5*y1 + b;
    x = x + dx + .25;
    y = y + dy + .25;
    if t >= 0 then output;
    x1 = dx; y1 = dy;
    a1 = a; b1 = b;
  end;
  keep t x y;
run;
```

The simulated series X and Y are shown in [Figure 26.1](#).

Figure 26.1 Example Series

Automatic State Space Model Selection

The STATESPACE procedure is designed to automatically select the best state space model for forecasting the series. You can specify your own model if you want, and you can use the output from PROC STATESPACE to help you identify a state space model. However, the easiest way to use PROC STATESPACE is to let it choose the model.

Stationarity and Differencing

Although PROC STATESPACE selects the state space model automatically, it does assume that the input series are stationary. If the series are nonstationary, then the process might fail. Therefore the first step is to examine your data and test to see if differencing is required. (See the section “Stationarity and Differencing” on page 1736 for further discussion of this issue.)

The series shown in Figure 26.1 are nonstationary. In order to forecast X and Y with a state space model, you must difference them (or use some other detrending method). If you fail to difference

when needed and try to use PROC STATESPACE with nonstationary data, an inappropriate state space model might be selected, and the model estimation might fail to converge.

The following statements identify and fit a state space model for the first differences of X and Y, and forecast X and Y 10 periods ahead:

```
proc statespace data=in out=out lead=10;
  var x(1) y(1);
  id t;
run;
```

The DATA= option specifies the input data set and the OUT= option specifies the output data set for the forecasts. The LEAD= option specifies forecasting 10 observations past the end of the input data. The VAR statement specifies the variables to forecast and specifies differencing. The notation X(1) Y(1) specifies that the state space model analyzes the first differences of X and Y.

Descriptive Statistics and Preliminary Autoregressions

The first page of the printed output produced by the preceding statements is shown in Figure 26.2.

Figure 26.2 Descriptive Statistics and VAR Order Selection

The STATESPACE Procedure								
Number of Observations								200
Variable	Mean	Standard Error						
x	0.144316	1.233457	Has been differenced. With period(s) = 1.					
y	0.164871	1.304358	Has been differenced. With period(s) = 1.					
The STATESPACE Procedure								
Information Criterion for Autoregressive Models

149.697	8.387786	5.517099	12.05986	15.36952	21.79538	24.00638	29.88874	33.55708
Information Criterion for Autoregressive Models								
				Lag=9	Lag=10			
				41.17606	47.70222			

Figure 26.2 *continued*

Schematic Representation of Correlations											
Name/Lag	0	1	2	3	4	5	6	7	8	9	10
x	++	++	++	++	++	++	+.	..	+.	+.	..
y	++	++	++	++	++	+.	+.	+.	+.
+ is > 2*std error, - is < -2*std error, . is between											

Descriptive statistics are printed first, giving the number of nonmissing observations after differencing and the sample means and standard deviations of the differenced series. The sample means are subtracted before the series are modeled (unless the NOCENTER option is specified), and the sample means are added back when the forecasts are produced.

Let X_t and Y_t be the observed values of X and Y, and let x_t and y_t be the values of X and Y after differencing and subtracting the mean difference. The series \mathbf{x}_t modeled by the STATESPACE procedure is

$$\mathbf{x}_t = \begin{bmatrix} x_t \\ y_t \end{bmatrix} = \begin{bmatrix} (1 - B)X_t - 0.144316 \\ (1 - B)Y_t - 0.164871 \end{bmatrix}$$

where B represents the backshift operator.

After the descriptive statistics, PROC STATESPACE prints the Akaike information criterion (AIC) values for the autoregressive models fit to the series. The smallest AIC value, in this case 5.517 at lag 2, determines the number of autocovariance matrices analyzed in the canonical correlation phase.

A schematic representation of the autocorrelations is printed next. This indicates which elements of the autocorrelation matrices at different lags are significantly greater than or less than 0.

The second page of the STATESPACE printed output is shown in Figure 26.3.

Figure 26.3 Partial Autocorrelations and VAR Model

y	0.292177		0.469297		-0.00537		-0.00048					

Figure 26.3 shows a schematic representation of the partial autocorrelations, similar to the autocorrelations shown in Figure 26.2. The selection of a second order autoregressive model by the AIC statistic looks reasonable in this case because the partial autocorrelations for lags greater than 2 are not significant.

Next, the Yule-Walker estimates for the selected autoregressive model are printed. This output shows the coefficient matrices of the vector autoregressive model at each lag.

Selected State Space Model Form and Preliminary Estimates

After the autoregressive order selection process has determined the number of lags to consider, the canonical correlation analysis phase selects the state vector. By default, output for this process is not printed. You can use the CANCORR option to print details of the canonical correlation analysis. See the section “Canonical Correlation Analysis Options” on page 1731 for an explanation of this process.

After the state vector is selected, the state space model is estimated by approximate maximum likelihood. Information from the canonical correlation analysis and from the preliminary autoregression is used to form preliminary estimates of the state space model parameters. These preliminary estimates are used as starting values for the iterative estimation process.

The form of the state vector and the preliminary estimates are printed next, as shown in Figure 26.4.

Figure 26.4 Preliminary Estimates of State Space Model

The STATESPACE Procedure		
Selected Statespace Form and Preliminary Estimates		
State Vector		
$x(T; T)$	$y(T; T)$	$x(T+1; T)$
Estimate of Transition Matrix		
0	0	1
0.291536	0.468762	-0.00411
0.24869	0.24484	0.204257
Input Matrix for Innovation		
1	0	
0	1	
0.257438	0.202237	
Variance Matrix for Innovation		
0.945196	0.100786	
0.100786	1.014703	

Figure 26.4 first prints the state vector as $X[T;T] \ Y[T;T] \ X[T+1;T]$. This notation indicates that the state vector is

$$\mathbf{z}_t = \begin{bmatrix} x_{t|t} \\ y_{t|t} \\ x_{t+1|t} \end{bmatrix}$$

The notation $x_{t+1|t}$ indicates the conditional expectation or prediction of x_{t+1} based on the information available at time t , and $x_{t|t}$ and $y_{t|t}$ are x_t and y_t , respectively.

The remainder of Figure 26.4 shows the preliminary estimates of the transition matrix \mathbf{F} , the input matrix \mathbf{G} , and the covariance matrix Σ_{ee} .

Estimated State Space Model

The next page of the STATESPACE output prints the final estimates of the fitted model, as shown in Figure 26.5. This output has the same form as in Figure 26.4, but it shows the maximum likelihood estimates instead of the preliminary estimates.

Figure 26.5 Fitted State Space Model

The STATESPACE Procedure		
Selected Statespace Form and Fitted Model		
State Vector		
$\mathbf{x}(T;T)$	$\mathbf{y}(T;T)$	$\mathbf{x}(T+1;T)$
Estimate of Transition Matrix		
0	0	1
0.297273	0.47376	-0.01998
0.2301	0.228425	0.256031
Input Matrix for Innovation		
1	0	
0	1	
0.257284	0.202273	
Variance Matrix for Innovation		
0.945188	0.100752	
0.100752	1.014712	

The estimated state space model shown in Figure 26.5 is

$$\begin{bmatrix} x_{t+1|t+1} \\ y_{t+1|t+1} \\ x_{t+2|t+1} \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 \\ 0.297 & 0.474 & -0.020 \\ 0.230 & 0.228 & 0.256 \end{bmatrix} \begin{bmatrix} x_t \\ y_t \\ x_{t+1|t} \end{bmatrix} + \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0.257 & 0.202 \end{bmatrix} \begin{bmatrix} e_{t+1} \\ n_{t+1} \end{bmatrix}$$

$$\text{var} \begin{bmatrix} e_{t+1} \\ n_{t+1} \end{bmatrix} = \begin{bmatrix} 0.945 & 0.101 \\ 0.101 & 1.015 \end{bmatrix}$$

The next page of the STATESPACE output lists the estimates of the free parameters in the **F** and **G** matrices with standard errors and *t* statistics, as shown in Figure 26.6.

Figure 26.6 Final Parameter Estimates

Parameter Estimates				
Parameter	Estimate	Standard Error	t Value	
F(2, 1)	0.297273	0.129995	2.29	
F(2, 2)	0.473760	0.115688	4.10	
F(2, 3)	-0.01998	0.313025	-0.06	
F(3, 1)	0.230100	0.126226	1.82	
F(3, 2)	0.228425	0.112978	2.02	
F(3, 3)	0.256031	0.305256	0.84	
G(3, 1)	0.257284	0.071060	3.62	
G(3, 2)	0.202273	0.068593	2.95	

Convergence Failures

The maximum likelihood estimates are computed by an iterative nonlinear maximization algorithm, which might not converge. If the estimates fail to converge, warning messages are printed in the output.

If you encounter convergence problems, you should recheck the stationarity of the data and ensure that the specified differencing orders are correct. Attempting to fit state space models to nonstationary data is a common cause of convergence failure. You can also use the MAXIT= option to increase the number of iterations allowed, or experiment with the convergence tolerance options DETTOL= and PARMTOL=.

Forecast Data Set

The following statements print the output data set. The WHERE statement excludes the first 190 observations from the output, so that only the forecasts and the last 10 actual observations are printed.

```
proc print data=out;
  id t;
  where t > 190;
run;
```

The PROC PRINT output is shown in Figure 26.7.

Figure 26.7 OUT= Data Set Produced by PROC STATESPACE

The OUT= data set produced by PROC STATESPACE contains the VAR and ID statement variables. In addition, for each VAR statement variable, the OUT= data set contains the variables FOR i , RES i , and STD i . These variables contain the predicted values, residuals, and forecast standard errors for the i th variable in the VAR statement list. In this case, X is listed first in the VAR statement, so FOR1 contains the forecasts of X, while FOR2 contains the forecasts of Y.

The following statements plot the forecasts and actuals for the series.

```
proc sgplot data=out noautolegend;
  where t > 150;
  series x=t y=for1 / markers
    markerattrs=(symbol=circle color=blue)
    lineattrs=(pattern=solid color=blue);
  series x=t y=for2 / markers
    markerattrs=(symbol=circle color=blue)
    lineattrs=(pattern=solid color=blue);
  series x=t y=x / markers
    markerattrs=(symbol=circle color=red)
    lineattrs=(pattern=solid color=red);
  series x=t y=y / markers
    markerattrs=(symbol=circle color=red)
    lineattrs=(pattern=solid color=red);
  refline 200.5 / axis=x;
run;
```

The forecast plot is shown in Figure 26.8. The last 50 observations are also plotted to provide context, and a reference line is drawn between the historical and forecast periods.

Figure 26.8 Plot of Forecasts

Controlling Printed Output

By default, the STATESPACE procedure produces a large amount of printed output. The NOPRINT option suppresses all printed output. You can suppress the printed output for the autoregressive model selection process with the PRINTOUT=NONE option. The descriptive statistics and state space model estimation output are still printed when PRINTOUT=NONE is specified. You can produce more detailed output with the PRINTOUT=LONG option and by specifying the printing control options CANCORR, COVB, and PRINT.

Specifying the State Space Model

Instead of allowing the STATESPACE procedure to select the model automatically, you can use FORM and RESTRICT statements to specify a state space model.

Specifying the State Vector

Use the FORM statement to control the form of the state vector. You can use this feature to force PROC STATESPACE to estimate and forecast a model different from the model it would select automatically. You can also use this feature to reestimate the automatically selected model (possibly with restrictions) without repeating the canonical correlation analysis.

The FORM statement specifies the number of lags of each variable to include in the state vector. For example, the statement FORM X 3; forces the state vector to include $x_{t|t}$, $x_{t+1|t}$, and $x_{t+2|t}$. The following statement specifies the state vector $(x_{t|t}, y_{t|t}, x_{t+1|t})$, which is the same state vector selected in the preceding example:

```
form x 2 y 1;
```

You can specify the form for only some of the variables and allow PROC STATESPACE to select the form for the other variables. If only some of the variables are specified in the FORM statement, canonical correlation analysis is used to determine the number of lags included in the state vector for the remaining variables not specified by the FORM statement. If the FORM statement includes specifications for all the variables listed in the VAR statement, the state vector is completely defined and the canonical correlation analysis is not performed.

Restricting the F and G matrices

After you know the form of the state vector, you can use the RESTRICT statement to fix some parameters in the **F** and **G** matrices to specified values. One use of this feature is to remove insignificant parameters by restricting them to 0.

In the introductory example shown in the preceding section, the F[2,3] parameter is not significant. (The parameters estimation output shown in [Figure 26.6](#) gives the *t* statistic for F[2,3] as -0.06. F[3,3] and F[3,1] also have low significance with $t < 2$.)

The following statements reestimate this model with F[2,3] restricted to 0. The FORM statement is used to specify the state vector and thus bypass the canonical correlation analysis.

```
proc statespace data=in out=out lead=10;
  var x(1) y(1);
  id t;
  form x 2 y 1;
  restrict f(2,3)=0;
run;
```

The final estimates produced by these statements are shown in [Figure 26.10](#).

Syntax: STATESPACE Procedure

The STATESPACE procedure uses the following statements:

PROC STATESPACE *options* ;
BY *variable* ... ;
FORM *variable value* ... ;
ID *variable* ;
INITIAL *F (row,column)=value ... G(row,column)=value ...* ;
RESTRICT *F (row,column)=value ... G (row,column)=value ...* ;
VAR *variable (difference, difference, ...)* ... ;

Functional Summary

Table 26.1 summarizes the statements and options used by PROC STATESPACE.

Table 26.1 STATESPACE Functional Summary

Description	Statement	Option
Input Data Set Options		
specify the input data set	PROC STATESPACE	DATA=
prevent subtraction of sample mean	PROC STATESPACE	NOCENTER
specify the ID variable	ID	
specify the observed series and differencing	VAR	
Options for Autoregressive Estimates		
specify the maximum order	PROC STATESPACE	ARMAX=
specify maximum lag for autocovariances	PROC STATESPACE	LAGMAX=
output only minimum AIC model	PROC STATESPACE	MINIC
specify the amount of detail printed	PROC STATESPACE	PRINTOUT=
write preliminary AR models to a data set	PROC STATESPACE	OUTAR=
Options for Canonical Correlation Analysis		
print the sequence of canonical correlations	PROC STATESPACE	CANCORR
specify upper limit of dimension of state vector	PROC STATESPACE	DIMMAX=
specify the minimum number of lags	PROC STATESPACE	PASTMIN=
specify the multiplier of the degrees of freedom	PROC STATESPACE	SIGCORR=
Options for State Space Model Estimation		
specify starting values	INITIAL	
print covariance matrix of parameter estimates	PROC STATESPACE	COVB
specify the convergence criterion	PROC STATESPACE	DETTOL=
specify the convergence criterion	PROC STATESPACE	PARMTOL=
print the details of the iterations	PROC STATESPACE	ITPRINT
specify an upper limit of the number of lags	PROC STATESPACE	KLAGE=
specify maximum number of iterations allowed	PROC STATESPACE	MAXIT=
suppress the final estimation	PROC STATESPACE	NOEST
write the state space model parameter estimates to an output data set	PROC STATESPACE	OUTMODEL=
use conditional least squares for final estimates	PROC STATESPACE	RESIDEST

Description	Statement	Option
specify criterion for testing for singularity	PROC STATESPACE	SINGULAR=
Options for Forecasting		
start forecasting before end of the input data	PROC STATESPACE	BACK=
specify the time interval between observations	PROC STATESPACE	INTERVAL=
specify multiple periods in the time series	PROC STATESPACE	INTPER=
specify how many periods to forecast	PROC STATESPACE	LEAD=
specify the output data set for forecasts	PROC STATESPACE	OUT=
print forecasts	PROC STATESPACE	PRINT
Options to Specify the State Space Model		
specify the state vector	FORM	
specify the parameter values	RESTRICT	
BY Groups		
specify BY-group processing	BY	
Printing		
suppresses all printed output	NOPRINT	

PROC STATESPACE Statement

PROC STATESPACE *options* ;

The following options can be specified in the PROC STATESPACE statement.

Printing Options

NOPRINT

suppresses all printed output.

Input Data Options

DATA=SAS-data-set

specifies the name of the SAS data set to be used by the procedure. If the DATA= option is omitted, the most recently created SAS data set is used.

LAGMAX=k

specifies the number of lags for which the sample autocovariance matrix is computed. The LAGMAX= option controls the number of lags printed in the schematic representation of the autocorrelations.

The sample autocovariance matrix of lag i , denoted as C_i , is computed as

$$C_i = \frac{1}{N-1} \sum_{t=1+i}^N \mathbf{x}_t \mathbf{x}'_{t-i}$$

where \mathbf{x}_t is the differenced and centered data and N is the number of observations. (If the NOCENTER option is specified, 1 is not subtracted from N .) LAGMAX= k specifies that C_0 through C_k are computed. The default is LAGMAX=10.

NOCENTER

prevents subtraction of the sample mean from the input series (after any specified differencing) before the analysis.

Options for Preliminary Autoregressive Models

ARMAX= n

specifies the maximum order of the preliminary autoregressive models. The ARMAX= option controls the autoregressive orders for which information criteria are printed, and controls the number of lags printed in the schematic representation of partial autocorrelations. The default is ARMAX=10. See the section “[Preliminary Autoregressive Models](#)” on page 1738 for details.

MINIC

writes to the OUTAR= data set only the preliminary Yule-Walker estimates for the VAR model that produces the minimum AIC. See the section “[OUTAR= Data Set](#)” on page 1749 for details.

OUTAR=*SAS-data-set*

writes the Yule-Walker estimates of the preliminary autoregressive models to a SAS data set. See the section “[OUTAR= Data Set](#)” on page 1749 for details.

PRINTOUT=SHORT | LONG | NONE

determines the amount of detail printed. PRINTOUT=LONG prints the lagged covariance matrices, the partial autoregressive matrices, and estimates of the residual covariance matrices from the sequence of autoregressive models. PRINTOUT=NONE suppresses the output for the preliminary autoregressive models. The descriptive statistics and state space model estimation output are still printed when PRINTOUT=NONE is specified. PRINTOUT=SHORT is the default.

Canonical Correlation Analysis Options

CANCORR

prints the canonical correlations and information criterion for each candidate state vector considered. See the section “[Canonical Correlation Analysis Options](#)” on page 1731 for details.

DIMMAX=*n*

specifies the upper limit to the dimension of the state vector. The DIMMAX= option can be used to limit the size of the model selected. The default is DIMMAX=10.

PASTMIN=*n*

specifies the minimum number of lags to include in the canonical correlation analysis. The default is PASTMIN=0. See the section “[Canonical Correlation Analysis Options](#)” on page 1731 for details.

SIGCORR=*value*

specifies the multiplier of the degrees of freedom for the penalty term in the information criterion used to select the state space form. The default is SIGCORR=2. The larger the value of the SIGCORR= option, the smaller the state vector tends to be. Hence, a large value causes a simpler model to be fit. See the section “[Canonical Correlation Analysis Options](#)” on page 1731 for details.

State Space Model Estimation Options

COVB

prints the inverse of the observed information matrix for the parameter estimates. This matrix is an estimate of the covariance matrix for the parameter estimates.

DETTOL=*value*

specifies the convergence criterion. The DETTOL= and PARMTOL= option values are used together to test for convergence of the estimation process. If, during an iteration, the relative change of the parameter estimates is less than the PARMTOL= value and the relative change of the determinant of the innovation variance matrix is less than the DETTOL= value, then iteration ceases and the current estimates are accepted. The default is DETTOL=1E-5.

ITPRINT

prints the iterations during the estimation process.

KLAG=*n*

sets an upper limit for the number of lags of the sample autocovariance matrix used in computing the approximate likelihood function. If the data have a strong moving average character, a larger KLAG= value might be necessary to obtain good estimates. The default is KLAG=15. See the section “[Parameter Estimation](#)” on page 1744 for details.

MAXIT=*n*

sets an upper limit to the number of iterations in the maximum likelihood or conditional least squares estimation. The default is MAXIT=50.

NOEST

suppresses the final maximum likelihood estimation of the selected model.

OUTMODEL=*SAS-data-set*

writes the parameter estimates and their standard errors to a SAS data set. See the section “[OUTMODEL= Data Set](#)” on page 1750 for details.

PARMTOL=*value*

specifies the convergence criterion. The DETTOL= and PARMTOL= option values are used together to test for convergence of the estimation process. If, during an iteration, the relative change of the parameter estimates is less than the PARMTOL= value and the relative change of the determinant of the innovation variance matrix is less than the DETTOL= value, then iteration ceases and the current estimates are accepted. The default is PARMTOL=0.001.

RESIDEST

computes the final estimates by using conditional least squares on the raw data. This type of estimation might be more stable than the default maximum likelihood method but is usually more computationally expensive. See the section “[Parameter Estimation](#)” on page 1744 for details about the conditional least squares method.

SINGULAR=*value*

specifies the criterion for testing for singularity of a matrix. A matrix is declared singular if a scaled pivot is less than the SINGULAR= value when sweeping the matrix. The default is SINGULAR=1E-7.

Forecasting Options**BACK=***n*

starts forecasting *n* periods before the end of the input data. The BACK= option value must not be greater than the number of observations. The default is BACK=0.

INTERVAL=*interval*

specifies the time interval between observations. The INTERVAL= value is used in conjunction with the ID variable to check that the input data are in order and have no missing periods. The INTERVAL= option is also used to extrapolate the ID values past the end of the input data. See Chapter 4, “[Date Intervals, Formats, and Functions](#),” for details about the INTERVAL= values allowed.

INTPER=*n*

specifies that each input observation corresponds to *n* time periods. For example, the options INTERVAL=MONTH and INTPER=2 specify bimonthly data and are equivalent to specifying INTERVAL=MONTH2. If the INTERVAL= option is not specified, the INTPER= option controls the increment used to generate ID values for the forecast observations. The default is INTPER=1.

LEAD=*n*

specifies how many forecast observations are produced. The forecasts start at the point set by the BACK= option. The default is LEAD=0, which produces no forecasts.

OUT=*SAS-data-set*

writes the residuals, actual values, forecasts, and forecast standard errors to a SAS data set. See the section “[OUT= Data Set](#)” on page 1749 for details.

PRINT

prints the forecasts.

BY Statement

BY *variable* ... ;

A BY statement can be used with the STATESPACE procedure to obtain separate analyses on observations in groups defined by the BY variables.

FORM Statement

FORM *variable value* ... ;

The FORM statement specifies the number of times a variable is included in the state vector. Values can be specified for any variable listed in the VAR statement. If a value is specified for each variable in the VAR statement, the state vector for the state space model is entirely specified, and automatic selection of the state space model is not performed.

The FORM statement forces the state vector, \mathbf{z}_t , to contain a specific variable a given number of times. For example, if Y is one of the variables in \mathbf{x}_t , then the statement

form y 3;

forces the state vector to contain Y_t , $Y_{t+1|t}$, and $Y_{t+2|t}$, possibly along with other variables.

The following statements illustrate the use of the FORM statement:

```
proc statespace data=in;
  var x y;
  form x 3 y 2;
run;
```

These statements fit a state space model with the following state vector:

$$\mathbf{z}_t = \begin{bmatrix} x_{t|t} \\ y_{t|t} \\ x_{t+1|t} \\ y_{t+1|t} \\ x_{t+2|t} \end{bmatrix}$$

ID Statement

ID *variable* ;

The ID statement specifies a variable that identifies observations in the input data set. The variable specified in the ID statement is included in the OUT= data set. The values of the ID variable are

extrapolated for the forecast observations based on the values of the INTERVAL= and INTPER= options.

INITIAL Statement

INITIAL *F*(row,column)= value ... *G*(row, column)= value ... ;

The INITIAL statement gives initial values to the specified elements of the **F** and **G** matrices. These initial values are used as starting values for the iterative estimation.

Parts of the **F** and **G** matrices represent fixed structural identities. If an element specified is a fixed structural element instead of a free parameter, the corresponding initialization is ignored.

The following is an example of an INITIAL statement:

```
initial f(3,2)=0 g(4,1)=0 g(5,1)=0;
```

RESTRICT Statement

RESTRICT *F*(row,column)= value ... *G*(row,column)= value ... ;

The RESTRICT statement restricts the specified elements of the **F** and **G** matrices to the specified values.

To use the restrict statement, you need to know the form of the model. Either specify the form of the model with the FORM statement, or do a preliminary run (perhaps with the NOEST option) to find the form of the model that PROC STATESPACE selects for the data.

The following is an example of a RESTRICT statement:

```
restrict f(3,2)=0 g(4,1)=0 g(5,1)=0 ;
```

Parts of the **F** and **G** matrices represent fixed structural identities. If a restriction is specified for an element that is a fixed structural element instead of a free parameter, the restriction is ignored.

VAR Statement

VAR *variable (difference, difference, ...) ...* ;

The VAR statement specifies the variables in the input data set to model and forecast. The VAR statement also specifies differencing of the input variables. The VAR statement is required.

Differencing is specified by following the variable name with a list of difference periods separated by commas. See the section “Stationarity and Differencing” on page 1736 for more information about differencing of input variables.

The order in which variables are listed in the VAR statement controls the order in which variables are included in the state vector. Usually, potential inputs should be listed before potential outputs.

For example, assuming the input data are monthly, the following VAR statement specifies modeling and forecasting of the one period and seasonal second difference of X and Y:

```
var x(1,12) y(1,12);
```

In this example, the vector time series analyzed is

$$\mathbf{x}_t = \begin{bmatrix} (1 - B)(1 - B^{12})X_t - \bar{x} \\ (1 - B)(1 - B^{12})Y_t - \bar{y} \end{bmatrix}$$

where B represents the back shift operator and \bar{x} and \bar{y} represent the means of the differenced series. If the NOCENTER option is specified, the mean differences are not subtracted.

Details: STATESPACE Procedure

Missing Values

The STATESPACE procedure does not support missing values. The procedure uses the first contiguous group of observations with no missing values for any of the VAR statement variables. Observations at the beginning of the data set with missing values for any VAR statement variable are not used or included in the output data set.

Stationarity and Differencing

The state space model used by the STATESPACE procedure assumes that the time series are stationary. Hence, the data should be checked for stationarity. One way to check for stationarity is to plot the series. A graph of series over time can show a time trend or variability changes.

You can also check stationarity by using the sample autocorrelation functions displayed by the ARIMA procedure. The autocorrelation functions of nonstationary series tend to decay slowly. See Chapter 7, “The ARIMA Procedure,” for more information.

Another alternative is to use the STATIONARITY= option in the IDENTIFY statement in PROC ARIMA to apply Dickey-Fuller tests for unit roots in the time series. See Chapter 7, “The ARIMA Procedure,” for more information about Dickey-Fuller unit root tests.

The most popular way to transform a nonstationary series to stationarity is by differencing. Differencing of the time series is specified in the VAR statement. For example, to take a simple first difference of the series X, use this statement:

```
var x(1);
```

In this example, the change in X from one period to the next is analyzed. When the series has a seasonal pattern, differencing at a period equal to the length of the seasonal cycle can be desirable. For example, suppose the variable X is measured quarterly and shows a seasonal cycle over the year. You can use the following statement to analyze the series of changes from the same quarter in the previous year:

```
var x(4);
```

To difference twice, add another differencing period to the list. For example, the following statement analyzes the series of second differences $(X_t - X_{t-1}) - (X_{t-1} - X_{t-2}) = X_t - 2X_{t-1} + X_{t-2}$:

```
var x(1,1);
```

The following statement analyzes the seasonal second difference series:

```
var x(1,4);
```

The series that is being modeled is the 1-period difference of the 4-period difference:

$$(X_t - X_{t-4}) - (X_{t-1} - X_{t-5}) = X_t - X_{t-1} - X_{t-4} + X_{t-5}.$$

Another way to obtain stationary series is to use a regression on time to detrend the data. If the time series has a deterministic linear trend, regressing the series on time produces residuals that should be stationary. The following statements write residuals of X and Y to the variable RX and RY in the output data set DETREND.

```
data a;
  set a;
  t=_n_;
run;

proc reg data=a;
  model x y = t;
  output out=detrend r=rx ry;
run;
```

You then use PROC STATESPACE to forecast the detrended series RX and RY. A disadvantage of this method is that you need to add the trend back to the forecast series in an additional step. A more serious disadvantage of the detrending method is that it assumes a deterministic trend. In practice, most time series appear to have a stochastic rather than a deterministic trend. Differencing is a more flexible and often more appropriate method.

There are several other methods to handle nonstationary time series. For more information and examples, see Brockwell and Davis (1991).

Preliminary Autoregressive Models

After computing the sample autocovariance matrices, PROC STATESPACE fits a sequence of vector autoregressive models. These preliminary autoregressive models are used to estimate the autoregressive order of the process and limit the order of the autocovariances considered in the state vector selection process.

Yule-Walker Equations for Forward and Backward Models

Unlike a univariate autoregressive model, a multivariate autoregressive model has different forms, depending on whether the present observation is being predicted from the past observations or from the future observations.

Let \mathbf{x}_t be the r -component stationary time series given by the VAR statement after differencing and subtracting the vector of sample means. (If the NOCENTER option is specified, the mean is not subtracted.) Let n be the number of observations of \mathbf{x}_t from the input data set.

Let \mathbf{e}_t be a vector white noise sequence with mean vector $\mathbf{0}$ and variance matrix Σ_p , and let \mathbf{n}_t be a vector white noise sequence with mean vector $\mathbf{0}$ and variance matrix Ω_p . Let p be the order of the vector autoregressive model for \mathbf{x}_t .

The forward autoregressive form based on the past observations is written as follows:

$$\mathbf{x}_t = \sum_{i=1}^p \Phi_i^p \mathbf{x}_{t-i} + \mathbf{e}_t$$

The backward autoregressive form based on the future observations is written as follows:

$$\mathbf{x}_t = \sum_{i=1}^p \Psi_i^p \mathbf{x}_{t+i} + \mathbf{n}_t$$

Letting E denote the expected value operator, the autocovariance sequence for the \mathbf{x}_t series, Γ_i , is

$$\Gamma_i = E \mathbf{x}_t \mathbf{x}'_{t-i}$$

The Yule-Walker equations for the autoregressive model that matches the first p elements of the autocovariance sequence are

$$\begin{bmatrix} \Gamma_0 & \Gamma_1 & \cdots & \Gamma_{p-1} \\ \Gamma_1' & \Gamma_0 & \cdots & \Gamma_{p-2} \\ \vdots & \vdots & \ddots & \vdots \\ \Gamma_{p-1}' & \Gamma_{p-2}' & \cdots & \Gamma_0 \end{bmatrix} \begin{bmatrix} \Phi_1^p \\ \Phi_2^p \\ \vdots \\ \Phi_p^p \end{bmatrix} = \begin{bmatrix} \Gamma_1 \\ \Gamma_2 \\ \vdots \\ \Gamma_p \end{bmatrix}$$

and

$$\begin{bmatrix} \Gamma_0 & \Gamma'_1 & \cdots & \Gamma'_{p-1} \\ \Gamma_1 & \Gamma_0 & \cdots & \Gamma'_{p-2} \\ \vdots & \vdots & & \vdots \\ \Gamma_{p-1} & \Gamma_{p-2} & \cdots & \Gamma_0 \end{bmatrix} \begin{bmatrix} \Psi_1^p \\ \Psi_2^p \\ \vdots \\ \Psi_p^p \end{bmatrix} = \begin{bmatrix} \Gamma'_1 \\ \Gamma'_2 \\ \vdots \\ \Gamma'_p \end{bmatrix}$$

Here Φ_i^p are the coefficient matrices for the past observation form of the vector autoregressive model, and Ψ_i^p are the coefficient matrices for the future observation form. More information about the Yule-Walker equations in the multivariate setting can be found in Whittle (1963) and Ansley and Newbold (1979).

The innovation variance matrices for the two forms can be written as follows:

$$\Sigma_p = \Gamma_0 - \sum_{i=1}^p \Phi_i^p \Gamma'_i$$

$$\Omega_p = \Gamma_0 - \sum_{i=1}^p \Psi_i^p \Gamma_i$$

The autoregressive models are fit to the data by using the preceding Yule-Walker equations with Γ_i replaced by the sample covariance sequence C_i . The covariance matrices are calculated as

$$C_i = \frac{1}{N-1} \sum_{t=i+1}^N \mathbf{x}_t \mathbf{x}'_{t-i}$$

Let $\hat{\Phi}_p$, $\hat{\Psi}_p$, $\hat{\Sigma}_p$, and $\hat{\Omega}_p$ represent the Yule-Walker estimates of Φ_p , Ψ_p , Σ_p , and Ω_p , respectively. These matrices are written to an output data set when the OUTAR= option is specified.

When the PRINTOUT=LONG option is specified, the sequence of matrices $\hat{\Sigma}_p$ and the corresponding correlation matrices are printed. The sequence of matrices $\hat{\Sigma}_p$ is used to compute Akaike information criteria for selection of the autoregressive order of the process.

Akaike Information Criterion

The Akaike information criterion (AIC) is defined as $-2(\text{maximum of log likelihood}) + 2(\text{number of parameters})$. Since the vector autoregressive models are estimates from the Yule-Walker equations, not by maximum likelihood, the exact likelihood values are not available for computing the AIC. However, for the vector autoregressive model the maximum of the log likelihood can be approximated as

$$\ln(L) \approx -\frac{n}{2} \ln(|\hat{\Sigma}_p|)$$

Thus, the AIC for the order p model is computed as

$$AIC_p = n \ln(|\hat{\Sigma}_p|) + 2pr^2$$

You can use the printed AIC array to compute a likelihood ratio test of the autoregressive order. The log-likelihood ratio test statistic for testing the order p model against the order $p - 1$ model is

$$-n\ln(|\widehat{\Sigma}_p|) + n\ln(|\widehat{\Sigma}_{p-1}|)$$

This quantity is asymptotically distributed as a χ^2 with r^2 degrees of freedom if the series is autoregressive of order $p - 1$. It can be computed from the AIC array as

$$AIC_{p-1} - AIC_p + 2r^2$$

You can evaluate the significance of these test statistics with the PROBCHI function in a SAS DATA step or with a χ^2 table.

Determining the Autoregressive Order

Although the autoregressive models can be used for prediction, their primary value is to aid in the selection of a suitable portion of the sample covariance matrix for use in computing canonical correlations. If the multivariate time series \mathbf{x}_t is of autoregressive order p , then the vector of past values to lag p is considered to contain essentially all the information relevant for prediction of future values of the time series.

By default, PROC STATESPACE selects the order p that produces the autoregressive model with the smallest AIC_p . If the value p for the minimum AIC_p is less than the value of the PASTMIN= option, then p is set to the PASTMIN= value. Alternatively, you can use the ARMAX= and PASTMIN= options to force PROC STATESPACE to use an order you select.

Significance Limits for Partial Autocorrelations

The STATESPACE procedure prints a schematic representation of the partial autocorrelation matrices that indicates which partial autocorrelations are significantly greater than or significantly less than 0. Figure 26.11 shows an example of this table.

Figure 26.11 Significant Partial Autocorrelations

Schematic Representation of Partial Autocorrelations										
Name/Lag	1	2	3	4	5	6	7	8	9	10
x	++	+
y	++
+ is > 2*std error, - is < -2*std error, . is between										

The partial autocorrelations are from the sample partial autoregressive matrices $\widehat{\Phi}_p^p$. The standard errors used for the significance limits of the partial autocorrelations are computed from the sequence of matrices Σ_p and Ω_p .

Under the assumption that the observed series arises from an autoregressive process of order $p - 1$, the p th sample partial autoregressive matrix $\widehat{\Phi}_p^p$ has an asymptotic variance matrix $\frac{1}{n}\Omega_p^{-1} \otimes \Sigma_p$.

The significance limits for $\widehat{\Phi}_p^p$ used in the schematic plot of the sample partial autoregressive sequence are derived by replacing Ω_p and Σ_p with their sample estimators to produce the variance estimate, as follows:

$$\widehat{Var}(\widehat{\Phi}_p^p) = \left(\frac{1}{n - rp} \right) \widehat{\Omega}_p^{-1} \otimes \widehat{\Sigma}_p$$

Canonical Correlation Analysis

Given the order p , let \mathbf{p}_t be the vector of current and past values relevant to prediction of \mathbf{x}_{t+1} :

$$\mathbf{p}_t = (\mathbf{x}'_t, \mathbf{x}'_{t-1}, \dots, \mathbf{x}'_{t-p})'$$

Let \mathbf{f}_t be the vector of current and future values:

$$\mathbf{f}_t = (\mathbf{x}'_t, \mathbf{x}'_{t+1}, \dots, \mathbf{x}'_{t+p})'$$

In the canonical correlation analysis, consider submatrices of the sample covariance matrix of \mathbf{p}_t and \mathbf{f}_t . This covariance matrix, \mathbf{V} , has a block Hankel form:

$$\mathbf{V} = \begin{bmatrix} \mathbf{C}_0 & \mathbf{C}'_1 & \mathbf{C}'_2 & \cdots & \mathbf{C}'_p \\ \mathbf{C}'_1 & \mathbf{C}'_2 & \mathbf{C}'_3 & \cdots & \mathbf{C}'_{p+1} \\ \vdots & \vdots & \vdots & \cdots & \vdots \\ \mathbf{C}'_p & \mathbf{C}'_{p+1} & \mathbf{C}'_{p+2} & \cdots & \mathbf{C}'_{2p} \end{bmatrix}$$

State Vector Selection Process

The canonical correlation analysis forms a sequence of potential state vectors \mathbf{z}_t^j . Examine a sequence \mathbf{f}_t^j of subvectors of \mathbf{f}_t , form the submatrix \mathbf{V}^j that consists of the rows and columns of \mathbf{V} that correspond to the components of \mathbf{f}_t^j , and compute its canonical correlations.

The smallest canonical correlation of \mathbf{V}^j is then used in the selection of the components of the state vector. The selection process is described in the following discussion. For more details about this process, see Akaike (1976).

In the following discussion, the notation $\mathbf{x}_{t+k|t}$ denotes the wide sense conditional expectation (best linear predictor) of \mathbf{x}_{t+k} , given all \mathbf{x}_s with s less than or equal to t . In the notation $x_{i,t+1}$, the first subscript denotes the i th component of \mathbf{x}_{t+1} .

The initial state vector \mathbf{z}_t^1 is set to \mathbf{x}_t . The sequence \mathbf{f}_t^j is initialized by setting

$$\mathbf{f}_t^1 = (\mathbf{z}_t^1, x_{1,t+1|t})' = (\mathbf{x}'_t, x_{1,t+1|t})'$$

That is, start by considering whether to add $x_{1,t+1|t}$ to the initial state vector \mathbf{z}_t^1 .

The procedure forms the submatrix \mathbf{V}^1 that corresponds to \mathbf{f}_t^1 and computes its canonical correlations. Denote the smallest canonical correlation of \mathbf{V}^1 as ρ_{min} . If ρ_{min} is significantly greater than 0, $x_{1,t+1|t}$ is added to the state vector.

If the smallest canonical correlation of \mathbf{V}^1 is not significantly greater than 0, then a linear combination of \mathbf{f}_t^1 is uncorrelated with the past, \mathbf{p}_t . Assuming that the determinant of \mathbf{C}_0 is not 0, (that is, no input series is a constant), you can take the coefficient of $x_{1,t+1|t}$ in this linear combination to be 1. Denote the coefficients of \mathbf{z}_t^1 in this linear combination as ℓ . This gives the relationship:

$$x_{1,t+1|t} = \ell' \mathbf{x}_t$$

Therefore, the current state vector already contains all the past information useful for predicting $x_{1,t+1}$ and any greater leads of $x_{1,t}$. The variable $x_{1,t+1|t}$ is not added to the state vector, nor are any terms $x_{1,t+k|t}$ considered as possible components of the state vector. The variable x_1 is no longer active for state vector selection.

The process described for $x_{1,t+1|t}$ is repeated for the remaining elements of \mathbf{f}_t . The next candidate for inclusion in the state vector is the next component of \mathbf{f}_t that corresponds to an active variable. Components of \mathbf{f}_t that correspond to inactive variables that produced a zero ρ_{min} in a previous step are skipped.

Denote the next candidate as $x_{l,t+k|t}$. The vector \mathbf{f}_t^j is formed from the current state vector and $x_{l,t+k|t}$ as follows:

$$\mathbf{f}_t^j = (\mathbf{z}_t^{j'}, x_{l,t+k|t})'$$

The matrix \mathbf{V}^j is formed from \mathbf{f}_t^j and its canonical correlations are computed. The smallest canonical correlation of \mathbf{V}^j is judged to be either greater than or equal to 0. If it is judged to be greater than 0, $x_{l,t+k|t}$ is added to the state vector. If it is judged to be 0, then a linear combination of \mathbf{f}_t^j is uncorrelated with the \mathbf{p}_t , and the variable x_l is now inactive.

The state vector selection process continues until no active variables remain.

Testing Significance of Canonical Correlations

For each step in the canonical correlation sequence, the significance of the smallest canonical correlation ρ_{min} is judged by an information criterion from Akaike (1976). This information criterion is

$$-n \ln(1 - \rho_{min}^2) - \lambda(r(p+1) - q + 1)$$

where q is the dimension of \mathbf{f}_t^j at the current step, r is the order of the state vector, p is the order of the vector autoregressive process, and λ is the value of the SIGCORR= option. The default is SIGCORR=2. If this information criterion is less than or equal to 0, ρ_{min} is taken to be 0; otherwise, it is taken to be significantly greater than 0. (Do not confuse this information criterion with the AIC.)

Variables in $\mathbf{x}_{t+p|t}$ are not added in the model, even with positive information criterion, because of the singularity of \mathbf{V} . You can force the consideration of more candidate state variables by increasing the size of the \mathbf{V} matrix by specifying a PASTMIN= option value larger than p .

Printing the Canonical Correlations

To print the details of the canonical correlation analysis process, specify the CANCELL option in the PROC STATESPACE statement. The CANCELL option prints the candidate state vectors, the canonical correlations, and the information criteria for testing the significance of the smallest canonical correlation.

Bartlett’s χ^2 and its degrees of freedom are also printed when the CANCELL option is specified. The formula used for Bartlett’s χ^2 is

$$\chi^2 = -(n - .5(r(p + 1) - q + 1))\ln(1 - \rho_{min}^2)$$

with $r(p + 1) - q + 1$ degrees of freedom.

Figure 26.12 shows the output of the CANCELL option for the introductory example shown in the “Getting Started: STATESPACE Procedure” on page 1718.

```
proc statespace data=in out=out lead=10 cancell;
  var x(1) y(1);
  id t;
run;
```

Figure 26.12 Canonical Correlations Analysis

The STATESPACE Procedure					
Canonical Correlations Analysis					
x(T;T)	y(T;T)	x(T+1;T)	Information Criterion	Chi Square	DF
1	1	0.237045	3.566167	11.4505	4

New variables are added to the state vector if the information criteria are positive. In this example, $y_{t+1|t}$ and $x_{t+2|t}$ are not added to the state space vector because the information criteria for these models are negative.

If the information criterion is nearly 0, then you might want to investigate models that arise if the opposite decision is made regarding ρ_{min} . This investigation can be accomplished by using a FORM statement to specify part or all of the state vector.

Preliminary Estimates of F

When a candidate variable $x_{l,t+k|t}$ yields a zero ρ_{min} and is not added to the state vector, a linear combination of f_t^j is uncorrelated with the p_t . Because of the method used to construct the f_t^j sequence, the coefficient of $x_{l,t+k|t}$ in \mathbf{l} can be taken as 1. Denote the coefficients of z_t^j in this linear combination as \mathbf{l} .

This gives the relationship:

$$x_{l,t+k|t} = \mathbf{l}'\mathbf{z}_t^j$$

The vector \mathbf{l} is used as a preliminary estimate of the first r columns of the row of the transition matrix \mathbf{F} corresponding to $x_{l,t+k-1|t}$.

Parameter Estimation

The model is $\mathbf{z}_{t+1} = \mathbf{Fz}_t + \mathbf{Ge}_{t+1}$, where \mathbf{e}_t is a sequence of independent multivariate normal innovations with mean vector $\mathbf{0}$ and variance Σ_{ee} . The observed sequence \mathbf{x}_t composes the first r components of \mathbf{z}_t , and thus $\mathbf{x}_t = \mathbf{Hz}_t$, where \mathbf{H} is the $r \times s$ matrix $[\mathbf{I}_r \ \mathbf{0}]$.

Let \mathbf{E} be the $r \times n$ matrix of innovations:

$$\mathbf{E} = [\mathbf{e}_1 \ \cdots \ \mathbf{e}_n]$$

If the number of observations n is reasonably large, the log likelihood L can be approximated up to an additive constant as follows:

$$L = -\frac{n}{2} \ln(|\Sigma_{ee}|) - \frac{1}{2} \text{trace}(\Sigma_{ee}^{-1} \mathbf{E}\mathbf{E}')$$

The elements of Σ_{ee} are taken as free parameters and are estimated as follows:

$$\mathbf{S}_0 = \frac{1}{n} \mathbf{E}\mathbf{E}'$$

Replacing Σ_{ee} by \mathbf{S}_0 in the likelihood equation, the log likelihood, up to an additive constant, is

$$\mathbf{L} = -\frac{n}{2} \ln(|\mathbf{S}_0|)$$

Letting B be the backshift operator, the formal relation between \mathbf{x}_t and \mathbf{e}_t is

$$\begin{aligned} \mathbf{x}_t &= \mathbf{H}(\mathbf{I} - B\mathbf{F})^{-1} \mathbf{G}\mathbf{e}_t \\ \mathbf{e}_t &= (\mathbf{H}(\mathbf{I} - B\mathbf{F})^{-1} \mathbf{G})^{-1} \mathbf{x}_t = \sum_{i=0}^{\infty} \mathbf{E}_i \mathbf{x}_{t-i} \end{aligned}$$

Letting \mathbf{C}_i be the i th lagged sample covariance of \mathbf{x}_t and neglecting end effects, the matrix \mathbf{S}_0 is

$$\mathbf{S}_0 = \sum_{i,j=0}^{\infty} \mathbf{E}_i \mathbf{C}_{-i+j} \mathbf{E}_j'$$

For the computation of \mathbf{S}_0 , the infinite sum is truncated at the value of the KLAG= option. The value of the KLAG= option should be large enough that the sequence \mathbf{E}_i is approximately 0 beyond that point.

Let $\boldsymbol{\theta}$ be the vector of free parameters in the \mathbf{F} and \mathbf{G} matrices. The derivative of the log likelihood with respect to the parameter $\boldsymbol{\theta}$ is

$$\frac{\partial L}{\partial \boldsymbol{\theta}} = -\frac{n}{2} \text{trace} \left(\mathbf{S}_0^{-1} \frac{\partial \mathbf{S}_0}{\partial \boldsymbol{\theta}} \right)$$

The second derivative is

$$\frac{\partial^2 L}{\partial \boldsymbol{\theta} \partial \boldsymbol{\theta}'} = \frac{n}{2} \left(\text{trace} \left(\mathbf{S}_0^{-1} \frac{\partial \mathbf{S}_0}{\partial \boldsymbol{\theta}'} \mathbf{S}_0^{-1} \frac{\partial \mathbf{S}_0}{\partial \boldsymbol{\theta}} \right) - \text{trace} \left(\mathbf{S}_0^{-1} \frac{\partial^2 \mathbf{S}_0}{\partial \boldsymbol{\theta} \partial \boldsymbol{\theta}'} \right) \right)$$

Near the maximum, the first term is unimportant and the second term can be approximated to give the following second derivative approximation:

$$\frac{\partial^2 L}{\partial \boldsymbol{\theta} \partial \boldsymbol{\theta}'} \cong -n \text{trace} \left(\mathbf{S}_0^{-1} \frac{\partial \mathbf{E}}{\partial \boldsymbol{\theta}} \frac{\partial \mathbf{E}'}{\partial \boldsymbol{\theta}'} \right)$$

The first derivative matrix and this second derivative matrix approximation are computed from the sample covariance matrix \mathbf{C}_0 and the truncated sequence $\bar{\mathbf{E}}_i$. The approximate likelihood function is maximized by a modified Newton-Raphson algorithm that employs these derivative matrices.

The matrix \mathbf{S}_0 is used as the estimate of the innovation covariance matrix, $\boldsymbol{\Sigma}_{ee}$. The negative of the inverse of the second derivative matrix at the maximum is used as an approximate covariance matrix for the parameter estimates. The standard errors of the parameter estimates printed in the parameter estimates tables are taken from the diagonal of this covariance matrix. The parameter covariance matrix is printed when the COVB option is specified.

If the data are nearly nonstationary, a better estimate of $\boldsymbol{\Sigma}_{ee}$ and the other parameters can sometimes be obtained by specifying the RESIDEST option. The RESIDEST option estimates the parameters by using conditional least squares instead of maximum likelihood.

The residuals are computed using the state space equation and the sample mean values of the variables in the model as start-up values. The estimate of \mathbf{S}_0 is then computed using the residuals from the i th observation on, where i is the maximum number of times any variable occurs in the state vector. A multivariate Gauss-Marquardt algorithm is used to minimize $|\mathbf{S}_0|$. See Harvey (1981a) for a further description of this method.

Forecasting

Given estimates of \mathbf{F} , \mathbf{G} , and $\boldsymbol{\Sigma}_{ee}$, forecasts of \mathbf{x}_t are computed from the conditional expectation of \mathbf{z}_t .

In forecasting, the parameters \mathbf{F} , \mathbf{G} , and $\boldsymbol{\Sigma}_{ee}$ are replaced with the estimates or by values specified in the RESTRICT statement. One-step-ahead forecasting is performed for the observation \mathbf{x}_t , where $t \leq n - b$. Here n is the number of observations and b is the value of the BACK= option. For the

observation \mathbf{x}_t , where $t > n - b$, m -step-ahead forecasting is performed for $m = t - n + b$. The forecasts are generated recursively with the initial condition $\mathbf{z}_0 = \mathbf{0}$.

The m -step-ahead forecast of \mathbf{z}_{t+m} is $\mathbf{z}_{t+m|t}$, where $\mathbf{z}_{t+m|t}$ denotes the conditional expectation of \mathbf{z}_{t+m} given the information available at time t . The m -step-ahead forecast of \mathbf{x}_{t+m} is $\mathbf{x}_{t+m|t} = \mathbf{H}\mathbf{z}_{t+m|t}$, where the matrix $\mathbf{H} = [\mathbf{I}_r \mathbf{0}]$.

Let $\Psi_i = \mathbf{F}^i \mathbf{G}$. Note that the last $s - r$ elements of \mathbf{z}_t consist of the elements of $\mathbf{x}_u|_t$ for $u > t$.

The state vector \mathbf{z}_{t+m} can be represented as

$$\mathbf{z}_{t+m} = \mathbf{F}^m \mathbf{z}_t + \sum_{i=0}^{m-1} \Psi_i \mathbf{e}_{t+m-i}$$

Since $\mathbf{e}_{t+i|t} = \mathbf{0}$ for $i > 0$, the m -step-ahead forecast $\mathbf{z}_{t+m|t}$ is

$$\mathbf{z}_{t+m|t} = \mathbf{F}^m \mathbf{z}_t = \mathbf{F}\mathbf{z}_{t+m-1|t}$$

Therefore, the m -step-ahead forecast of \mathbf{x}_{t+m} is

$$\mathbf{x}_{t+m|t} = \mathbf{H}\mathbf{z}_{t+m|t}$$

The m -step-ahead forecast error is

$$\mathbf{z}_{t+m} - \mathbf{z}_{t+m|t} = \sum_{i=0}^{m-1} \Psi_i \mathbf{e}_{t+m-i}$$

The variance of the m -step-ahead forecast error is

$$\mathbf{V}_{z,m} = \sum_{i=0}^{m-1} \Psi_i \Sigma_{ee} \Psi_i'$$

Letting $\mathbf{V}_{z,0} = \mathbf{0}$, the variance of the m -step-ahead forecast error of \mathbf{z}_{t+m} , $\mathbf{V}_{z,m}$, can be computed recursively as follows:

$$\mathbf{V}_{z,m} = \mathbf{V}_{z,m-1} + \Psi_{m-1} \Sigma_{ee} \Psi_{m-1}'$$

The variance of the m -step-ahead forecast error of \mathbf{x}_{t+m} is the $r \times r$ left upper submatrix of $\mathbf{V}_{z,m}$; that is,

$$\mathbf{V}_{x,m} = \mathbf{H}\mathbf{V}_{z,m}\mathbf{H}'$$

Unless the NOCENTER option is specified, the sample mean vector is added to the forecast. When differencing is specified, the forecasts $\mathbf{x}_{t+m|t}$ plus the sample mean vector are integrated back to produce forecasts for the original series.

Let \mathbf{y}_t be the original series specified by the VAR statement, with some 0 values appended that correspond to the unobserved past observations. Let \mathbf{B} be the backshift operator, and let $\Delta(\mathbf{B})$ be the

$s \times s$ matrix polynomial in the backshift operator that corresponds to the differencing specified by the VAR statement. The off-diagonal elements of Δ_i are 0. Note that $\Delta_0 = \mathbf{I}_s$, where \mathbf{I}_s is the $s \times s$ identity matrix. Then $\mathbf{z}_t = \Delta(B)\mathbf{y}_t$.

This gives the relationship

$$\mathbf{y}_t = \Delta^{-1}(B)\mathbf{z}_t = \sum_{i=0}^{\infty} \Lambda_i \mathbf{z}_{t-i}$$

where $\Delta^{-1}(B) = \sum_{i=0}^{\infty} \Lambda_i B^i$ and $\Lambda_0 = \mathbf{I}_s$.

The m -step-ahead forecast of \mathbf{y}_{t+m} is

$$\mathbf{y}_{t+m|t} = \sum_{i=0}^{m-1} \Lambda_i \mathbf{z}_{t+m-i|t} + \sum_{i=m}^{\infty} \Lambda_i \mathbf{z}_{t+m-i}$$

The m -step-ahead forecast error of \mathbf{y}_{t+m} is

$$\sum_{i=0}^{m-1} \Lambda_i (\mathbf{z}_{t+m-i} - \mathbf{z}_{t+m-i|t}) = \sum_{i=0}^{m-1} \left(\sum_{u=0}^i \Lambda_u \Psi_{i-u} \right) \mathbf{e}_{t+m-i}$$

Letting $\mathbf{V}_{y,0} = \mathbf{0}$, the variance of the m -step-ahead forecast error of \mathbf{y}_{t+m} , $\mathbf{V}_{y,m}$, is

$$\begin{aligned} \mathbf{V}_{y,m} &= \sum_{i=0}^{m-1} \left(\sum_{u=0}^i \Lambda_u \Psi_{i-u} \right) \Sigma_{ee} \left(\sum_{u=0}^i \Lambda_u \Psi_{i-u} \right)' \\ &= \mathbf{V}_{y,m-1} + \left(\sum_{u=0}^{m-1} \Lambda_u \Psi_{m-1-u} \right) \Sigma_{ee} \left(\sum_{u=0}^{m-1} \Lambda_u \Psi_{m-1-u} \right)' \end{aligned}$$

Relation of ARMA and State Space Forms

Every state space model has an ARMA representation, and conversely every ARMA model has a state space representation. This section discusses this equivalence. The following material is adapted from Akaike (1974), where there is a more complete discussion. Pham-Dinh-Tuan (1978) also contains a discussion of this material.

Suppose you are given the following ARMA model:

$$\Phi(B)\mathbf{x}_t = \Theta(B)\mathbf{e}_t$$

or, in more detail,

$$\mathbf{x}_t - \Phi_1 \mathbf{x}_{t-1} - \cdots - \Phi_p \mathbf{x}_{t-p} = \mathbf{e}_t + \Theta_1 \mathbf{e}_{t-1} + \cdots + \Theta_q \mathbf{e}_{t-q} \quad (1)$$

where \mathbf{e}_t is a sequence of independent multivariate normal random vectors with mean $\mathbf{0}$ and variance matrix Σ_{ee} , B is the backshift operator ($B\mathbf{x}_t = \mathbf{x}_{t-1}$), $\Phi(B)$ and $\Theta(B)$ are matrix polynomials in B , and \mathbf{x}_t is the observed process.

If the roots of the determinantal equation $|\Phi(B)| = 0$ are outside the unit circle in the complex plane, the model can also be written as

$$\mathbf{x}_t = \Phi^{-1}(B)\Theta(B)\mathbf{e}_t = \sum_{i=0}^{\infty} \Psi_i \mathbf{e}_{t-i}$$

The Ψ_i matrices are known as the impulse response matrices and can be computed as $\Phi^{-1}(B)\Theta(B)$.

You can assume $p > q$ since, if this is not initially true, you can add more terms Φ_i that are identically 0 without changing the model.

To write this set of equations in a state space form, proceed as follows. Let $\mathbf{x}_{t+i|t}$ be the conditional expectation of \mathbf{x}_{t+i} given \mathbf{x}_w for $w \leq t$. The following relations hold:

$$\begin{aligned} \mathbf{x}_{t+i|t} &= \sum_{j=i}^{\infty} \Psi_j \mathbf{e}_{t+i-j} \\ \mathbf{x}_{t+i|t+1} &= \mathbf{x}_{t+i|t} + \Psi_{i-1} \mathbf{e}_{t+1} \end{aligned}$$

However, from equation (1) you can derive the following relationship:

$$\mathbf{x}_{t+p|t} = \Phi_1 \mathbf{x}_{t+p-1|t} + \cdots + \Phi_p \mathbf{x}_t \quad (2)$$

Hence, when $i = p$, you can substitute for $\mathbf{x}_{t+p|t}$ in the right-hand side of equation (2) and close the system of equations.

This substitution results in the following model in the state space form $\mathbf{z}_{t+1} = \mathbf{F}\mathbf{z}_t + \mathbf{G}\mathbf{e}_{t+1}$:

$$\begin{bmatrix} \mathbf{x}_{t+1} \\ \mathbf{x}_{t+2|t+1} \\ \vdots \\ \mathbf{x}_{t+p|t+1} \end{bmatrix} = \begin{bmatrix} 0 & \mathbf{I} & 0 & \cdots & 0 \\ 0 & 0 & \mathbf{I} & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \Phi_p & \Phi_{p-1} & \cdots & \Phi_1 & \end{bmatrix} \begin{bmatrix} \mathbf{x}_t \\ \mathbf{x}_{t+1|t} \\ \vdots \\ \mathbf{x}_{t+p-1|t} \end{bmatrix} + \begin{bmatrix} \mathbf{I} \\ \Psi_1 \\ \vdots \\ \Psi_{p-1} \end{bmatrix} \mathbf{e}_{t+1}$$

Note that the state vector \mathbf{z}_t is composed of conditional expectations of \mathbf{x}_t and the first r components of \mathbf{z}_t are equal to \mathbf{x}_t .

The state space form can be cast into an ARMA form by solving the system of difference equations for the first r components.

When converting from an ARMA form to a state space form, you can generate a state vector larger than needed; that is, the state space model might not be a minimal representation. When going from a state space form to an ARMA form, you can have nontrivial common factors in the autoregressive and moving average operators that yield an ARMA model larger than necessary.

If the state space form used is not a minimal representation, some but not all components of $\mathbf{x}_{t+i|t}$ might be linearly dependent. This situation corresponds to $[\Phi_p \Theta_{p-1}]$ being of less than full rank when $\Phi(B)$ and $\Theta(B)$ have no common nontrivial left factors. In this case, \mathbf{z}_t consists of a subset of the possible components of $[\mathbf{x}_{t+i|t}] \quad i = 1, 2, \dots, p-1$. However, once a component of $\mathbf{x}_{t+i|t}$ (for example, the j th one) is linearly dependent on the previous conditional expectations, then all subsequent j th components of $\mathbf{x}_{t+k|t}$ for $k > i$ must also be linearly dependent. Note that in this case, equivalent but seemingly different structures can arise if the order of the components within \mathbf{x}_t is changed.

OUT= Data Set

The forecasts are contained in the output data set specified by the OUT= option in the PROC STATESPACE statement. The OUT= data set contains the following variables:

- the BY variables
- the ID variable
- the VAR statement variables. These variables contain the actual values from the input data set.
- FOR i , numeric variables that contain the forecasts. The variable FOR i contains the forecasts for the i th variable in the VAR statement list. Forecasts are one-step-ahead predictions until the end of the data or until the observation specified by the BACK= option.
- RES i , numeric variables that contain the residual for the forecast of the i th variable in the VAR statement list. For forecast observations, the actual values are missing and the RES i variables contain missing values.
- STD i , numeric variables that contain the standard deviation for the forecast of the i th variable in the VAR statement list. The values of the STD i variables can be used to construct univariate confidence limits for the corresponding forecasts. However, such confidence limits do not take into account the covariance of the forecasts.

OUTAR= Data Set

The OUTAR= data set contains the estimates of the preliminary autoregressive models. The OUTAR= data set contains the following variables:

- ORDER, a numeric variable that contains the order p of the autoregressive model that the observation represents
- AIC, a numeric variable that contains the value of the information criterion AIC_p
- SIGF l , numeric variables that contain the estimate of the innovation covariance matrices for the forward autoregressive models. The variable SIGF l contains the l th column of $\widehat{\Sigma}_p$ in the observations with ORDER= p .
- SIGB l , numeric variables that contain the estimate of the innovation covariance matrices for the backward autoregressive models. The variable SIGB l contains the l th column of $\widehat{\Omega}_p$ in the observations with ORDER= p .
- FOR k_l , numeric variables that contain the estimates of the autoregressive parameter matrices for the forward models. The variable FOR k_l contains the l th column of the lag k autoregressive parameter matrix $\widehat{\Phi}_k^p$ in the observations with ORDER= p .

- **BACK_l**, numeric variables that contain the estimates of the autoregressive parameter matrices for the backward models. The variable **BACK_l** contains the *l*th column of the lag *k* autoregressive parameter matrix $\hat{\Psi}_k^p$ in the observations with **ORDER**=*p*.

The estimates for the order *p* autoregressive model can be selected as those observations with **ORDER**=*p*. Within these observations, the *k,l*th element of Φ_i^p is given by the value of the **FORi_l** variable in the *k*th observation. The *k,l*th element of Ψ_i^p is given by the value of **BACi_l** variable in the *k*th observation. The *k,l*th element of Σ_p is given by **SIGFl** in the *k*th observation. The *k,l*th element of Ω_p is given by **SIGBl** in the *k*th observation.

Table 26.2 shows an example of the **OUTAR=** data set, with **ARMAX**=3 and \mathbf{x}_t of dimension 2. In Table 26.2, (*i, j*) indicate the *i,j*th element of the matrix.

The estimated autoregressive parameters can be used in the **IML** procedure to obtain autoregressive estimates of the spectral density function or forecasts based on the autoregressive models.

OUTMODEL= Data Set

The **OUTMODEL=** data set contains the estimates of the **F** and **G** matrices and their standard errors, the names of the components of the state vector, and the estimates of the innovation covariance matrix. The variables contained in the **OUTMODEL=** data set are as follows:

- the **BY** variables
- **STATEVEC**, a character variable that contains the name of the component of the state vector corresponding to the observation. The **STATEVEC** variable has the value **STD** for standard deviations observations, which contain the standard errors for the estimates given in the preceding observation.

- F_j , numeric variables that contain the columns of the \mathbf{F} matrix. The variable F_j contains the j th column of \mathbf{F} . The number of F_j variables is equal to the value of the DIMMAX= option. If the model is of smaller dimension, the extraneous variables are set to missing.
- G_j , numeric variables that contain the columns of the \mathbf{G} matrix. The variable G_j contains the j th column of \mathbf{G} . The number of G_j variables is equal to r , the dimension of \mathbf{x}_t given by the number of variables in the VAR statement.
- SIG_j , numeric variables that contain the columns of the innovation covariance matrix. The variable SIG_j contains the j th column of Σ_{ee} . There are r variables SIG_j .

Table 26.3 shows an example of the OUTMODEL= data set, with $\mathbf{x}_t = (x_t, y_t)'$, $\mathbf{z}_t = (x_t, y_t, x_{t+1|t})'$, and DIMMAX=4. In Table 26.3, $F_{i,j}$ and $G_{i,j}$ are the i,j th elements of \mathbf{F} and \mathbf{G} respectively. Note that all elements for F_4 are missing because \mathbf{F} is a 3×3 matrix.

Printed Output

The printed output produced by the STATESPACE procedure includes the following:

1. descriptive statistics, which include the number of observations used, the names of the variables, their means and standard deviations (Std), and the differencing operations used
2. the Akaike information criteria for the sequence of preliminary autoregressive models
3. if the PRINTOUT=LONG option is specified, the sample autocovariance matrices of the input series at various lags
4. if the PRINTOUT=LONG option is specified, the sample autocorrelation matrices of the input series
5. a schematic representation of the autocorrelation matrices, showing the significant autocorrelations
6. if the PRINTOUT=LONG option is specified, the partial autoregressive matrices. (These are Φ_p^p as described in the section “Preliminary Autoregressive Models” on page 1738.)

7. a schematic representation of the partial autocorrelation matrices, showing the significant partial autocorrelations
8. the Yule-Walker estimates of the autoregressive parameters for the autoregressive model with the minimum AIC
9. if the PRINTOUT=LONG option is specified, the autocovariance matrices of the residuals of the minimum AIC model. This is the sequence of estimated innovation variance matrices for the solutions of the Yule-Walker equations.
10. if the PRINTOUT=LONG option is specified, the autocorrelation matrices of the residuals of the minimum AIC model
11. If the CANCORR option is specified, the canonical correlations analysis for each potential state vector considered in the state vector selection process. This includes the potential state vector, the canonical correlations, the information criterion for the smallest canonical correlation, Bartlett's χ^2 statistic ("Chi Square") for the smallest canonical correlation, and the degrees of freedom of Bartlett's χ^2 .
12. the components of the chosen state vector
13. the preliminary estimate of the transition matrix, **F**, the input matrix, **G**, and the variance matrix for the innovations, Σ_{ee}
14. if the ITPRINT option is specified, the iteration history of the likelihood maximization. For each iteration, this shows the iteration number, the number of step halvings, the determinant of the innovation variance matrix, the damping factor Lambda, and the values of the parameters.
15. the state vector, printed again to aid interpretation of the following listing of **F** and **G**
16. the final estimate of the transition matrix **F**
17. the final estimate of the input matrix **G**
18. the final estimate of the variance matrix for the innovations Σ_{ee}
19. a table that lists the estimates of the free parameters in **F** and **G** and their standard errors and *t* statistics
20. if the COVB option is specified, the covariance matrix of the parameter estimates
21. if the COVB option is specified, the correlation matrix of the parameter estimates
22. if the PRINT option is specified, the forecasts and their standard errors

ODS Table Names

PROC STATESPACE assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 26.4 ODS Tables Produced in PROC STATESPACE

ODS Table Name	Description	Option
NObs	number of observations	default
Summary	simple summary statistics table	default
InfoCriterion	information criterion table	default
CovLags	covariance matrices of input series	PRINTOUT=LONG
CorrLags	correlation matrices of input series	PRINTOUT=LONG
PartialAR	partial autoregressive matrices	PRINTOUT=LONG
YWEstimates	Yule-Walker estimates for minimum AIC	default
CovResiduals	covariance of residuals	PRINTOUT=LONG
CorrResiduals	residual correlations from AR models	PRINTOUT=LONG
StateVector	state vector table	default
CorrGraph	schematic representation of correlations	default
TransitionMatrix	transition matrix	default
InputMatrix	input matrix	default
VarInnov	variance matrix for the innovation	default
CovB	covariance of parameter estimates	COVB
CorrB	correlation of parameter estimates	COVB
CanCorr	canonical correlation analysis	CANCORR
IterHistory	iterative fitting table	ITPRINT
ParameterEstimates	parameter estimates table	default
Forecasts	forecasts table	PRINT
ConvergenceStatus	convergence status table	default

Examples: STATESPACE Procedure

Example 26.1: Series J from Box and Jenkins

This example analyzes the gas furnace data (series J) from Box and Jenkins. (The data are not shown; see Box and Jenkins (1976) for the data.)

First, a model is selected and fit automatically using the following statements.

```

title1 'Gas Furnace Data';
title2 'Box & Jenkins Series J';
title3 'Automatically Selected Model';

proc statespace data=seriesj cancorr;
  var x y;
run;

```

The results for the automatically selected model are shown in [Output 26.1.1](#).

The two series are believed to have a transfer function relation with the gas rate (variable X) as the input and the CO₂ concentration (variable Y) as the output. Since the parameter estimates shown in [Output 26.1.1](#) support this kind of model, the model is reestimated with the feedback parameters restricted to 0. The following statements fit the transfer function (no feedback) model.

```

title3 'Transfer Function Model';
proc statespace data=seriesj printout=none;
  var x y;
  restrict f(3,2)=0 f(3,4)=0
          g(3,2)=0 g(4,1)=0 g(5,1)=0;
run;

```

The last two pages of the output are shown in [Output 26.1.8](#).

Overview: SYSLIN Procedure

The SYSLIN procedure estimates parameters in an interdependent system of linear regression equations.

Ordinary least squares (OLS) estimates are biased and inconsistent when current period endogenous variables appear as regressors in other equations in the system. The errors of a set of related regression equations are often correlated, and the efficiency of the estimates can be improved by taking these correlations into account. The SYSLIN procedure provides several techniques that produce consistent and asymptotically efficient estimates for systems of regression equations.

The SYSLIN procedure provides the following estimation methods:

- ordinary least squares (OLS)
- two-stage least squares (2SLS)
- limited information maximum likelihood (LIML)
- K-class
- seemingly unrelated regressions (SUR)
- iterated seemingly unrelated regressions (ITSUR)
- three-stage least squares (3SLS)
- iterated three-stage least squares (IT3SLS)
- full information maximum likelihood (FIML)
- minimum expected loss (MELO)

Other features of the SYSLIN procedure enable you to:

- impose linear restrictions on the parameter estimates
- test linear hypotheses about the parameters
- write predicted and residual values to an output SAS data set
- write parameter estimates to an output SAS data set
- write the crossproducts matrix (SSCP) to an output SAS data set
- use raw data, correlations, covariances, or cross products as input

Getting Started: SYSLIN Procedure

This section introduces the use of the SYSLIN procedure. The problem of dependent regressors is introduced using a supply and demand example. This section explains the terminology used for variables in a system of regression equations and introduces the SYSLIN procedure statements for declaring the roles the variables play. The syntax used for the different estimation methods and the output produced is shown.

An Example Model

In simultaneous systems of equations, endogenous variables are determined jointly rather than sequentially. Consider the following supply and demand functions for some product:

$$Q_D = a_1 + b_1P + c_1Y + d_1S + \epsilon_1(\text{demand})$$

$$Q_S = a_2 + b_2P + c_2U + \epsilon_2(\text{supply})$$

$$Q = Q_D = Q_S(\text{market equilibrium})$$

The variables in this system are as follows:

Q_D	quantity demanded
Q_S	quantity supplied
Q	the observed quantity sold, which equates quantity supplied and quantity demanded in equilibrium
P	price per unit
Y	income
S	price of substitutes

U	unit cost
ϵ_1	the random error term for the demand equation
ϵ_2	the random error term for the supply equation

In this system, quantity demanded depends on price, income, and the price of substitutes. Consumers normally purchase more of a product when prices are lower and when income and the price of substitute goods are higher. Quantity supplied depends on price and the unit cost of production. Producers supply more when price is high and when unit cost is low. The actual price and quantity sold are determined jointly by the values that equate demand and supply.

Since price and quantity are jointly endogenous variables, both structural equations are necessary to adequately describe the observed values. A critical assumption of OLS is that the regressors are uncorrelated with the residual. When current endogenous variables appear as regressors in other equations (endogenous variables depend on each other), this assumption is violated and the OLS parameter estimates are biased and inconsistent. The bias caused by the violated assumptions is called *simultaneous equation bias*. Neither the demand nor supply equation can be estimated consistently by OLS.

Variables in a System of Equations

Before explaining how to use the SYSLIN procedure, it is useful to define some terms. The variables in a system of equations can be classified as follows:

- *Endogenous variables*, which are also called *jointly dependent* or *response variables*, are the variables determined by the system. Endogenous variables can also appear on the right-hand side of equations.
- *Exogenous variables* are independent variables that do not depend on any of the endogenous variables in the system.
- *Predetermined variables* include both the exogenous variables and *lagged endogenous variables*, which are past values of endogenous variables determined at previous time periods. PROC SYSLIN does not compute lagged values; any lagged endogenous variables must be computed in a preceding DATA step.
- *Instrumental variables* are predetermined variables used in obtaining predicted values for the current period endogenous variables by a first-stage regression. The use of instrumental variables characterizes estimation methods such as two-stage least squares and three-stage least squares. Instrumental variables estimation methods substitute these first-stage predicted values for endogenous variables when they appear as regressors in model equations.

Using PROC SYSLIN

First specify the input data set and estimation method in the PROC SYSLIN statement. If any model uses dependent regressors, and you are using an instrumental variables regression method, declare the dependent regressors with an ENDOGENOUS statement and declare the instruments with an INSTRUMENTS statement. Next, use MODEL statements to specify the structural equations of the system.

The use of different estimation methods is shown by the following examples. These examples use the simulated dataset WORK.IN given below.

```
data in;
  label q = "Quantity"
        p = "Price"
        s = "Price of Substitutes"
        y = "Income"
        u = "Unit Cost";
  drop i e1 e2;
  p = 0; q = 0;
  do i = 1 to 60;
    y = 1 + .05*i + .15*rannor(123);
    u = 2 + .05*rannor(123) + .05*rannor(123);
    s = 4 - .001*(i-10)*(i-110) + .5*rannor(123);
    e1 = .15 * rannor(123);
    e2 = .15 * rannor(123);
    demandx = 1 + .3 * y + .35 * s + e1;
    supplyx = -1 - 1 * u + e2 - .4*e1;
    q = 1.4/2.15 * demandx + .75/2.15 * supplyx;
    p = ( - q + supplyx ) / -1.4;
  output;
end;
run;
```

OLS Estimation

PROC SYSLIN performs OLS regression if you do not specify a method of estimation in the PROC SYSLIN statement. OLS does not use instruments, so the ENDOGENOUS and INSTRUMENTS statements can be omitted.

The following statements estimate the supply and demand model shown previously:

```
proc syslin data=in;
  demand: model q = p y s;
  supply: model q = p u;
run;
```

The PROC SYSLIN output for the demand equation is shown in [Figure 27.1](#), and the output for the supply equation is shown in [Figure 27.2](#).

	Root MSE	0.13267	R-Square	0.90004		
	Dependent Mean	1.30095	Adj R-Sq	0.89653		
	Coeff Var	10.19821				

Figure 27.2 *continued*

Parameter Estimates						
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t	Variable Label
Intercept	1	-0.30389	0.471397	-0.64	0.5217	Intercept
p	1	1.218743	0.053914	22.61	<.0001	Price
u	1	-1.07757	0.234150	-4.60	<.0001	Unit Cost

For each MODEL statement, the output first shows the model label and dependent variable name and label. This is followed by an analysis-of-variance table for the model, which shows the model, error, and total mean squares, and an F test for the no-regression hypothesis. Next, the procedure prints the root mean squared error, dependent variable mean and coefficient of variation, and the R^2 and adjusted R^2 statistics.

Finally, the table of parameter estimates shows the estimated regression coefficients, standard errors, and t tests. You would expect the price coefficient in a demand equation to be negative. However, note that the OLS estimate of the price coefficient P in the demand equation (0.1233) has a positive sign. This could be caused by simultaneous equation bias.

Two-Stage Least Squares Estimation

In the supply and demand model, P is an endogenous variable, and consequently the OLS estimates are biased. The following example estimates this model using two-stage least squares.

```
proc syslin data=in 2sls;
  endogenous p;
  instruments y u s;
  demand: model q = p y s;
  supply: model q = p u;
run;
```

The 2SLS option in the PROC SYSLIN statement specifies the two-stage least squares method. The ENDOGENOUS statement specifies that P is an endogenous regressor for which first-stage predicted values are substituted. You need to declare an endogenous variable in the ENDOGENOUS statement only if it is used as a regressor; thus although Q is endogenous in this model, it is not necessary to list it in the ENDOGENOUS statement.

Usually, all predetermined variables that appear in the system are used as instruments. The INSTRUMENTS statement specifies that the exogenous variables Y, U, and S are used as instruments for the first-stage regression to predict P.

The 2SLS results are shown in Figure 27.3 and Figure 27.4. The first-stage regressions are not shown. To see the first-stage regression results, use the FIRST option in the PROC SYSLIN statement.

Figure 27.4 2SLS Results for Supply Equation

The SYSLIN Procedure						
Two-Stage Least Squares Estimation						
Model			SUPPLY			
Dependent Variable			q			
Label			Quantity			
Analysis of Variance						
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F	
Model	2	9.646109	4.823054	253.96	<.0001	
Error	57	1.082503	0.018991			
Corrected Total	59	10.03724				
	Root MSE	0.13781	R-Square	0.89910		
	Dependent Mean	1.30095	Adj R-Sq	0.89556		
	Coeff Var	10.59291				

Figure 27.4 *continued*

Parameter Estimates						
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t	Variable Label
Intercept	1	-0.51878	0.490999	-1.06	0.2952	Intercept
p	1	1.333080	0.059271	22.49	<.0001	Price
u	1	-1.14623	0.243491	-4.71	<.0001	Unit Cost

The 2SLS output is similar in form to the OLS output. However, the 2SLS results are based on predicted values for the endogenous regressors from the first stage instrumental regressions. This makes the analysis-of-variance table and the R^2 statistics difficult to interpret. See the sections “ANOVA Table for Instrumental Variables Methods” on page 1798 and “The R-Square Statistics” on page 1799 for details.

Note that, unlike the OLS results, the 2SLS estimate for the P coefficient in the demand equation (-1.115) is negative.

LIML, K-Class, and MELO Estimation

To obtain limited information maximum likelihood, general K-class, or minimum expected loss estimates, use the ENDOGENOUS, INSTRUMENTS, and MODEL statements as in the 2SLS case but specify the LIML, K=, or MELO option instead of 2SLS in the PROC SYSLIN statement. The following statements show this for K-class estimation.

```
proc syslin data=in k=.5;
  endogenous p;
  instruments y u s;
  demand: model q = p y s;
  supply: model q = p u;
run;
```

For more information about these estimation methods, see the section “Estimation Methods” on page 1795 and consult econometrics textbooks.

SUR, 3SLS, and FIML Estimation

In a multivariate regression model, the errors in different equations might be correlated. In this case, the efficiency of the estimation might be improved by taking these cross-equation correlations into account.

Seemingly Unrelated Regression

Seemingly unrelated regression (SUR), also called joint generalized least squares (JGLS) or Zellner estimation, is a generalization of OLS for multi-equation systems. Like OLS, the SUR method assumes that all the regressors are independent variables, but SUR uses the correlations among the errors in different equations to improve the regression estimates. The SUR method requires an initial OLS regression to compute residuals. The OLS residuals are used to estimate the cross-equation covariance matrix.

The SUR option in the PROC SYSLIN statement specifies seemingly unrelated regression, as shown in the following statements:

```
proc syslin data=in sur;
  demand: model q = p y s;
  supply: model q = p u;
run;
```

INSTRUMENTS and ENDOGENOUS statements are not needed for SUR, because the SUR method assumes there are no endogenous regressors. For SUR to be effective, the models must use different regressors. SUR produces the same results as OLS unless the model contains at least one regressor not used in the other equations.

Three-Stage Least Squares

The three-stage least squares method generalizes the two-stage least squares method to take into account the correlations between equations in the same way that SUR generalizes OLS. Three-stage least squares requires three steps: first-stage regressions to get predicted values for the endogenous regressors; a two-stage least squares step to get residuals to estimate the cross-equation correlation matrix; and the final 3SLS estimation step.

The 3SLS option in the PROC SYSLIN statement specifies the three-stage least squares method, as shown in the following statements.

```
proc syslin data=in 3sls;
  endogenous p;
  instruments y u s;
  demand: model q = p y s;
  supply: model q = p u;
run;
```

The 3SLS output begins with a two-stage least squares regression to estimate the cross-model correlation matrix. This output is the same as the 2SLS results shown in [Figure 27.3](#) and [Figure 27.4](#), and is not repeated here. The next part of the 3SLS output prints the cross-model correlation matrix computed from the 2SLS residuals. This output is shown in [Figure 27.5](#) and includes the cross-model covariances, correlations, the inverse of the correlation matrix, and the inverse covariance matrix.

Figure 27.6 continued

		Model		SUPPLY		
		Dependent Variable		q		
		Label		Quantity		
Parameter Estimates						
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t	Variable Label
Intercept	1	-0.51878	0.490999	-1.06	0.2952	Intercept
p	1	1.333080	0.059271	22.49	<.0001	Price
u	1	-1.14623	0.243491	-4.71	<.0001	Unit Cost

This output first prints the system weighted mean squared error and system weighted R^2 statistics. The system weighted MSE and system weighted R^2 measure the fit of the joint model obtained by stacking all the models together and performing a single regression with the stacked observations weighted by the inverse of the model error variances. See the section “The R-Square Statistics” on page 1799 for details.

Next, the table of 3SLS parameter estimates for each model is printed. This output has the same form as for the other estimation methods.

Note that, in some cases, the 3SLS and 2SLS results can be the same. Such a case could arise because of the same principle that causes OLS and SUR results to be identical, unless an equation includes a regressor not used in the other equations of the system. However, the application of this principle is more complex when instrumental variables are used. When all the exogenous variables are used as instruments, linear combinations of all the exogenous variables appear in the third-stage regressions through substitution of first-stage predicted values.

In this example, 3SLS produces different (and, it is hoped, more efficient) estimates for the demand equation. However, the 3SLS and 2SLS results for the supply equation are the same. This is because the supply equation has one endogenous regressor and one exogenous regressor not used in other equations. In contrast, the demand equation has fewer endogenous regressors than exogenous regressors not used in other equations in the system.

Full Information Maximum Likelihood

The FIML option in the PROC SYSLIN statement specifies the full information maximum likelihood method, as shown in the following statements.

```
proc syslin data=in fiml;
  endogenous p q;
  instruments y u s;
  demand: model q = p y s;
  supply: model q = p u;
run;
```

The FIML results are shown in Figure 27.7.

Computing Reduced Form Estimates

A system of structural equations with endogenous regressors can be represented as functions of only the predetermined variables. For this to be possible, there must be as many equations as endogenous variables. If there are more endogenous variables than regression models, you can use `IDENTITY` statements to complete the system. See the section “[Reduced Form Estimates](#)” on page 1801 for details.

The `REDUCED` option in the `PROC SYSLIN` statement prints reduced form estimates. The following statements show this by using the 3SLS estimates of the structural parameters.

```
proc syslin data=in 3sls reduced;
  endogenous p;
  instruments y u s;
  demand: model q = p y s;
  supply: model q = p u;
run;
```

The first four pages of this output were as shown previously and are not repeated here. (See Figure 27.3, Figure 27.4, Figure 27.5, and Figure 27.6.) The final page of the output from this example contains the reduced form coefficients from the 3SLS structural estimates, as shown in Figure 27.8.

Figure 27.8 Reduced Form 3SLS Results

Restricting Parameter Estimates

You can impose restrictions on the parameter estimates with `RESTRICT` and `SRESTRICT` statements. The `RESTRICT` statement imposes linear restrictions on parameters in the equation specified by the preceding `MODEL` statement. The `SRESTRICT` statement imposes linear restrictions that relate parameters in different models.

To impose restrictions involving parameters in different equations, use the `SRESTRICT` statement. Specify the parameters in the linear hypothesis as *model-label.regressor-name*. (If the `MODEL` statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.)

Tests for the significance of the restrictions are printed when RESTRICT or SRESTRICT statements are used. You can label RESTRICT and SRESTRICT statements to identify the restrictions in the output.

The RESTRICT statement in the following example restricts the price coefficient in the demand equation to equal 0.015. The SRESTRICT statement restricts the estimate of the income coefficient in the demand equation to be 0.01 times the estimate of the unit cost coefficient in the supply equation.

```
proc syslin data=in 3sls;
  endogenous p;
  instruments y u s;
  demand: model q = p y s;
  peq015: restrict p = .015;
  supply: model q = p u;
  yeq01u: srestrict demand.y = .01 * supply.u;
run;
```

The restricted estimation results are shown in Figure 27.9.

Figure 27.9 Restricted Estimates

The SYSLIN Procedure						
Three-Stage Least Squares Estimation						
Model			DEMAND			
Dependent Variable			q			
Label			Quantity			
Parameter Estimates						
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t	Variable Label
Intercept	1	-0.46584	0.053307	-8.74	<.0001	Intercept

u	1	-0.67887	0.235679	-2.88	0.0056	Unit Cost

Figure 27.9 continued

Parameter Estimates						
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t	Variable Label
RESTRICT	-1	342.3605	38.12094	8.98	<.0001	YEQ01U

The standard error for P in the demand equation is 0, since the value of the P coefficient was specified by the RESTRICT statement and not estimated from the data. The “Parameter Estimates” table for the demand equation contains an additional row for the restriction specified by the RESTRICT statement. The parameter estimate for the restriction is the value of the Lagrange multiplier used to impose the restriction. The restriction is highly significant ($t = 6.777$), which means that the data are not consistent with the restriction, and the model does not fit as well with the restriction imposed. See the section “RESTRICT Statement” on page 1789 for details.

Following the “Parameter Estimates” table for the supply equation, the results for the cross model restrictions are printed. This shows that the restriction specified by the SRESTRICT statement is not consistent with the data ($t = 8.98$). See the section “SRESTRICT Statement” on page 1790 for details.

Testing Parameters

You can test linear hypotheses about the model parameters with TEST and STEST statements. The TEST statement tests hypotheses about parameters in the equation specified by the preceding MODEL statement. The STEST statement tests hypotheses that relate parameters in different models.

For example, the following statements test the hypothesis that the price coefficient in the demand equation is equal to 0.015.

```

/*--- 3SLS Estimation with Tests ---*/

proc syslin data=in 3sls;
  endogenous p;
  instruments y u s;
  demand: model q = p y s;
  test_1: test p = .015;
  supply: model q = p u;
run;

```

The TEST statement results are shown in Figure 27.10. This reports an F test for the hypothesis specified by the TEST statement. In this case, the F statistic is 6.79 (3.879/.571) with 1 and 113 degrees of freedom. The p value for this F statistic is 0.0104, which indicates that the hypothesis tested is almost but not quite rejected at the 0.01 level. See the section “TEST Statement” on page 1792 for details.

Figure 27.10 TEST Statement Results

The SYSLIN Procedure						
Three-Stage Least Squares Estimation						
System Weighted MSE		0.5711

Intercept	1	1.980269	1.169176	1.69	0.0959	Intercept
p	1	-1.17654	0.605015	-1.94	0.0568	Price
y	1	0.404117	0.117179	3.45	0.0011	Income
s	1	0.359204	0.085077	4.22	<.0001	Price of Substitutes
Test Results						
Num DF	Den DF	F Value	Pr > F	Label		
1	113	6.79	0.0104	TEST_1		

To test hypotheses that involve parameters in different equations, use the `STEST` statement. Specify the parameters in the linear hypothesis as *model-label.regressor-name*. (If the `MODEL` statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.)

For example, the following statements test the hypothesis that the income coefficient in the demand equation is 0.01 times the unit cost coefficient in the supply equation:

```
proc syslin data=in 3sls;
  endogenous p;
  instruments y u s;
  demand: model q = p y s;
  supply: model q = p u;
  stest1: stest demand.y = .01 * supply.u;
run;
```

The `STEST` statement results are shown in Figure 27.11. The form and interpretation of the `STEST` statement results are like the `TEST` statement results. In this case, the *F* test produces a *p* value less than 0.0001, and strongly rejects the hypothesis tested. See the section “`STEST` Statement” on page 1791 for details.

Figure 27.11 STEST Statement Results

The SYSLIN Procedure						
Three-Stage Least Squares Estimation

Test Results						
Num DF	Den DF	F Value	Pr > F	Label		
1	113	22.46	0.0001	STEST1		

You can combine TEST and STEST statements with RESTRICT and SRESTRICT statements to perform hypothesis tests for restricted models. Of course, the validity of the TEST and STEST statement results depends on the correctness of any restrictions you impose on the estimates.

Saving Residuals and Predicted Values

You can store predicted values and residuals from the estimated models in a SAS data set. Specify the OUT= option in the PROC SYSLIN statement and use the OUTPUT statement to specify names for new variables to contain the predicted and residual values.

For example, the following statements store the predicted quantity from the supply and demand equations in a data set PRED:

```

/*--- Saving Output Data from 3SLS Estimation ---*/

proc syslin data=in out=pred 3sls;
  endogenous  p;
  instruments y u s;
  demand: model q = p y s;
  output predicted=q_demand;
  supply: model q = p u;
  output predicted=q_supply;
run;

```

Plotting Residuals

You can plot the residuals against the regressors by using the PROC SGPLOT. For example, the following statements plot the 2SLS residuals for the demand model against price, income, and price of substitutes.

```

proc syslin data=in 2sls out=out;
  endogenous  p;
  instruments y u s;
  demand: model q = p y s;
  output residual=residual_q;
run;

proc sgplot data=out;
  scatter x=p y=residual_q;
  refline 0 / axis=y;
run;

proc sgplot data=out;
  scatter x=y y=residual_q;
  refline 0 / axis=y;
run;

proc sgplot data=out;
  scatter x=s y=residual_q;
  refline 0 / axis=y;
run;

```

The plot for income is shown in [Figure 27.12](#). The other plots are not shown.

Figure 27.12 Plot of Residuals against Income

Syntax: SYSLIN Procedure

The SYSLIN procedure uses the following statements:

```

PROC SYSLIN options ;
  BY variables ;
  ENDOGENOUS variables ;
  IDENTITY identities ;
  INSTRUMENTS variables ;
  MODEL response = regressors / options ;
  OUTPUT PREDICTED= variable RESIDUAL= variable ;
  RESTRICT restrictions ;
  SRESTRICT restrictions ;
  STEST equations ;
  TEST equations ;
  VAR variables ;
  WEIGHT variable ;

```

Functional Summary

The SYSLIN procedure statements and options are summarized in the following table.

Description	Statement	Option
Data Set Options		
specify the input data set	PROC SYSLIN	DATA=
specify the output data set	PROC SYSLIN	OUT=
write parameter estimates to an output data set	PROC SYSLIN	OUTEST=
write covariances to the OUTEST= data set	PROC SYSLIN	OUTCOV OUTCOV3
write the SSCP matrix to an output data set	PROC SYSLIN	OUTSSCP=
Estimation Method Options		
specify full information maximum likelihood estimation	PROC SYSLIN	FIML
specify iterative SUR estimation	PROC SYSLIN	ITSUR
specify iterative 3SLS estimation	PROC SYSLIN	IT3SLS
specify K-class estimation	PROC SYSLIN	K=
specify limited information maximum likelihood estimation	PROC SYSLIN	LIML
specify minimum expected loss estimation	PROC SYSLIN	MELO
specify ordinary least squares estimation	PROC SYSLIN	OLS
specify seemingly unrelated estimation	PROC SYSLIN	SUR
specify two-stage least squares estimation	PROC SYSLIN	2SLS
specify three-stage least squares estimation	PROC SYSLIN	3SLS
specify Fuller's modification to LIML	PROC SYSLIN	ALPHA=
specify convergence criterion	PROC SYSLIN	CONVERGE=
specify maximum number of iterations	PROC SYSLIN	MAXIT=
use diagonal of \mathbf{S} instead of \mathbf{S}	PROC SYSLIN	SDIAG
exclude RESTRICT statements in final stage	PROC SYSLIN	NOINCLUDE
specify criterion for testing for singularity	PROC SYSLIN	SINGULAR=
specify denominator for variance estimates	PROC SYSLIN	VARDEF=
Printing Control Options		
print all results	PROC SYSLIN	ALL
print first-stage regression statistics	PROC SYSLIN	FIRST
print estimates and SSE at each iteration	PROC SYSLIN	ITPRINT
print the reduced form estimates	PROC SYSLIN	REDUCED
print descriptive statistics	PROC SYSLIN	SIMPLE
print uncorrected SSCP matrix	PROC SYSLIN	USSCP
print correlations of the parameter estimates	MODEL	CORRB

Description	Statement	Option
print covariances of the parameter estimates	MODEL	COVB
print Durbin-Watson statistics	MODEL	DW
print Basman's test	MODEL	OVERID
plot residual values against regressors	MODEL	PLOT
print standardized parameter estimates	MODEL	STB
print unrestricted parameter estimates	MODEL	UNREST
print the model crossproducts matrix	MODEL	XPX
print the inverse of the crossproducts matrix	MODEL	I
suppress printed output	MODEL	NOPRINT
suppress all printed output	PROC SYSLIN	NOPRINT
Model Specification		
specify structural equations	MODEL	
suppress the intercept parameter	MODEL	NOINT
specify linear relationship among variables	IDENTITY	
perform weighted regression	WEIGHT	
Tests and Restrictions on Parameters		
place restrictions on parameter estimates	RESTRICT	
place restrictions on parameter estimates	SRESTRICT	
test linear hypothesis	STEST	
test linear hypothesis	TEST	
Other Statements		
specify BY-group processing	BY	
specify the endogenous variables	ENDOGENOUS	
specify instrumental variables	INSTRUMENTS	
write predicted and residual values to a data set	OUTPUT	
name variable for predicted values	OUTPUT	PREDICTED=
name variable for residual values	OUTPUT	RESIDUAL=
include additional variables in $X'X$ matrix	VAR	

PROC SYSLIN Statement

PROC SYSLIN *options* ;

The following options can be used with the PROC SYSLIN statement.

Data Set Options

DATA=SAS-data-set

specifies the input data set. If the DATA= option is omitted, the most recently created SAS data set is used. In addition to ordinary SAS data sets, PROC SYSLIN can analyze data sets of TYPE=CORR, TYPE=COV, TYPE=UCORR, TYPE=UCOV, and TYPE=SSCP. See the section “[Special TYPE= Input Data Sets](#)” on page 1795 for details.

OUT=SAS-data-set

specifies an output SAS data set for residuals and predicted values. The OUT= option is used in conjunction with the OUTPUT statement. See the section “[OUT= Data Set](#)” on page 1803 for details.

OUTEST=SAS-data-set

writes the parameter estimates to an output data set. See the section “[OUTEST= Data Set](#)” on page 1803 for details.

OUTCOV

COVOUT

writes the covariance matrix of the parameter estimates to the OUTEST= data set in addition to the parameter estimates.

OUTCOV3

COV3OUT

writes covariance matrices for each model in a system to the OUTEST= data set when the 3SLS, SUR, or FIML option is used.

OUTSSCP=SAS-data-set

writes the sum-of-squares-and-crossproducts matrix to an output data set. See the section “[OUTSSCP= Data Set](#)” on page 1804 for details.

Estimation Method Options

2SLS

specifies the two-stage least squares estimation method.

3SLS

specifies the three-stage least squares estimation method.

ALPHA=value

specifies Fuller’s modification to the LIML estimation method. See the section “[Fuller’s Modification to LIML](#)” on page 1802 for details.

CONVERGE=value

specifies the convergence criterion for the iterative estimation methods IT3SLS, ITSUR, and FIML. The default is CONVERGE=0.0001.

FIML

specifies the full information maximum likelihood estimation method.

ITSUR

specifies the iterative seemingly unrelated estimation method.

IT3SLS

specifies the iterative three-stage least squares estimation method.

K=value

specifies the K-class estimation method.

LIML

specifies the limited information maximum likelihood estimation method.

MAXITER=n

specifies the maximum number of iterations allowed for the IT3SLS, ITSUR, and FIML estimation methods. The MAXITER= option can be abbreviated as MAXIT=. The default is MAXITER=30.

MELO

specifies the minimum expected loss estimation method.

NOINCLUDE

excludes the RESTRICT statements from the final stage for the 3SLS, IT3SLS, SUR, and ITSUR estimation methods.

OLS

specifies the ordinary least squares estimation method. This is the default.

SDIAG

uses the diagonal of **S** instead of **S** to do the estimation, where **S** is the covariance matrix of equation errors. See the section “[Uncorrelated Errors across Equations](#)” on page 1802 for details.

SINGULAR=value

specifies a criterion for testing singularity of the crossproducts matrix. This is a tuning parameter used to make PROC SYSLIN more or less sensitive to singularities. The value must be between 0 and 1. The default is SINGULAR=1E-8.

SUR

specifies the seemingly unrelated estimation method.

Printing Control Options**ALL**

specifies the CORRB, COVB, DW, I, OVERID, PLOT, STB, and XPX options for every MODEL statement.

FIRST

prints first-stage regression statistics for the endogenous variables regressed on the instruments. This output includes sums of squares, estimates, variances, and standard deviations.

ITPRINT

prints parameter estimates, system-weighted residual sum of squares, and R^2 at each iteration for the IT3SLS and ITSUR estimation methods. For the FIML method, the ITPRINT option prints parameter estimates, negative of log-likelihood function, and norm of gradient vector at each iteration.

NOPRINT

suppresses all printed output. Specifying NOPRINT in the PROC SYSLIN statement is equivalent to specifying NOPRINT in every MODEL statement.

REDUCED

prints the reduced form estimates. If the REDUCED option is specified, you should specify any IDENTITY statements needed to make the system square. See the section “[Reduced Form Estimates](#)” on page 1801 for details.

SIMPLE

prints descriptive statistics for the dependent variables. The statistics printed include the sum, mean, uncorrected sum of squares, variance, and standard deviation.

USSCP

prints the uncorrected sum-of-squares-and-crossproducts matrix.

USSCP2

prints the uncorrected sum-of-squares-and-crossproducts matrix for all variables used in the analysis, including predicted values of variables generated by the procedure.

VARDEF=DF | N | WEIGHT | WGT

specifies the denominator to use in calculating cross-equation error covariances and parameter standard errors and covariances. The default is VARDEF=DF, which corrects for model degrees of freedom. VARDEF=N specifies no degrees-of-freedom correction. VARDEF=WEIGHT specifies the sum of the observation weights. VARDEF=WGT specifies the sum of the observation weights minus the model degrees of freedom. See the section “[Computation of Standard Errors](#)” on page 1801 for details.

BY Statement

BY *variables* ;

A BY statement can be used with PROC SYSLIN to obtain separate analyses on observations in groups defined by the BY variables.

ENDOGENOUS Statement

ENDOGENOUS *variables* ;

The ENDOGENOUS statement declares the jointly dependent variables that are projected in the first-stage regression through the instrument variables. The ENDOGENOUS statement is not needed for the SUR, ITSUR, or OLS estimation methods. The default ENDOGENOUS list consists of all the dependent variables in the MODEL and IDENTITY statements that do not appear in the INSTRUMENTS statement.

IDENTITY Statement

IDENTITY *equation* ;

The IDENTITY statement specifies linear relationships among variables to write to the OUTEST= data set. It provides extra information in the OUTEST= data set but does not create or compute variables. The OUTEST= data set can be processed by the SIMLIN procedure in a later step.

The IDENTITY statement is also used to compute reduced form coefficients when the REDUCED option in the PROC SYSLIN statement is specified. See the section “[Reduced Form Estimates](#)” on page 1801 for details.

The *equation* given by the IDENTITY statement has the same form as equations in the MODEL statement. A label can be specified for an IDENTITY statement as follows:

label : **IDENTITY** ... ;

INSTRUMENTS Statement

INSTRUMENTS *variables* ;

The INSTRUMENTS statement declares the variables used in obtaining first-stage predicted values. All the instruments specified are used in each first-stage regression. The INSTRUMENTS statement is required for the 2SLS, 3SLS, IT3SLS, LIML, MELO, and K-class estimation methods. The INSTRUMENTS statement is not needed for the SUR, ITSUR, OLS, or FIML estimation methods.

MODEL Statement

MODEL *response = regressors / options* ;

The MODEL statement regresses the response variable on the left side of the equal sign against the regressors listed on the right side.

Models can be given labels. Model labels are used in the printed output to identify the results for different models. Model labels are also used in SRESTRICT and STEST statements to refer to parameters in different models. If no label is specified, the response variable name is used as the label for the model. The model label is specified as follows:

label : **MODEL** ...;

The following options can be used in the MODEL statement after a slash (/).

ALL

specifies the CORR, COVB, DW, I, OVERID, PLOT, STB, and XPX options.

ALPHA=*value*

specifies the α parameter for Fuller's modification to the LIML estimation method. See the section "Fuller's Modification to LIML" on page 1802 for details.

CORR

prints the matrix of estimated correlations between the parameter estimates.

COVB

prints the matrix of estimated covariances between the parameter estimates.

DW

prints Durbin-Watson statistics and autocorrelation coefficients for the residuals. If there are missing values, d' is calculated according to Savin and White (1978). Use the DW option only if the data set to be analyzed is an ordinary SAS data set with time series observations sorted in time order. The Durbin-Watson test is not valid for models with lagged dependent regressors.

I

prints the inverse of the crossproducts matrix for the model, $(\mathbf{X}'\mathbf{X})^{-1}$. If restrictions are specified, the crossproducts matrix printed is adjusted for the restrictions. See the section "Computational Details" on page 1799 for details.

K=*value*

specifies K-class estimation.

NOINT

suppresses the intercept parameter from the model.

NOPRINT

suppresses the normal printed output.

OVERID

prints Basman's (1960) test for over identifying restrictions. See the section "Overidentification Restrictions" on page 1802 for details.

PLOT

plots residual values against regressors. A plot of the residuals for each regressor is printed.

STB

prints standardized parameter estimates. Sometimes known as a standard partial regression coefficient, a standardized parameter estimate is a parameter estimate multiplied by the standard deviation of the associated regressor and divided by the standard deviation of the response variable.

UNREST

prints parameter estimates computed before restrictions are applied. The UNREST option is valid only if a RESTRICT statement is specified.

XPX

prints the model crossproducts matrix, $X'X$. See the section “Computational Details” on page 1799 for details.

OUTPUT Statement

OUTPUT < *PREDICTED=variable* > < *RESIDUAL=variable* > ;

The OUTPUT statement writes predicted values and residuals from the preceding model to the data set specified by the OUT= option in the PROC SYSLIN statement. An OUTPUT statement must come after the MODEL statement to which it applies. The OUT= option must be specified in the PROC SYSLIN statement.

The following options can be specified in the OUTPUT statement:

PREDICTED=variable

names a new variable to contain the predicted values for the response variable. The PREDICTED= option can be abbreviated as PREDICT=, PRED=, or P=.

RESIDUAL=variable

names a new variable to contain the residual values for the response variable. The RESIDUAL= option can be abbreviated as RESID= or R=.

For example, the following statements create an output data set named B. In addition to the variables in the input data set, the data set B contains the variable YHAT, with values that are predicted values of the response variable Y, and YRESID, with values that are the residual values of Y.

```
proc syslin data=a out=b;
  model y = x1 x2;
  output p=yhat r=yresid;
run;
```

For example, the following statements create an output data set named PRED. In addition to the variables in the input data set, the data set PRED contains the variables Q_DEMAND and Q_SUPPLY, with values that are predicted values of the response variable Q for the demand and supply equations respectively, and R_DEMAND and R_SUPPLY, with values that are the residual values of the demand and supply equations respectively.

```
proc syslin data=in out=pred;
  demand: model q = p y s;
  output p=q_demand r=r_demand;
  supply: model q = p u;
```

```

output p=q_supply r=r_supply;
run;

```

See the section “OUT= Data Set” on page 1803 for details.

RESTRICT Statement

RESTRICT *equation* , ... , *equation* ;

The RESTRICT statement places restrictions on the parameter estimates for the preceding MODEL statement. Any number of RESTRICT statements can follow a MODEL statement. Each restriction is written as a linear equation. If more than one restriction is specified in a single RESTRICT statement, the restrictions are separated by commas.

Parameters are referred to by the name of the corresponding regressor variable. Each name used in the equation must be a regressor in the preceding MODEL statement. The keyword INTERCEPT is used to refer to the intercept parameter in the model.

RESTRICT statements can be given labels. The labels are used in the printed output to distinguish results for different restrictions. Labels are specified as follows:

label : **RESTRICT** ...;

The following is an example of the use of the RESTRICT statement, in which the coefficients of the regressors X1 and X2 are required to sum to 1.

```

proc syslin data=a;
  model y = x1 x2;
  restrict x1 + x2 = 1;
run;

```

Variable names can be multiplied by constants. When no equal sign appears, the linear combination is set equal to 0. Note that the parameters associated with the variables are restricted, not the variables themselves. Here are some examples of valid RESTRICT statements:

```

restrict x1 + x2 = 1;
restrict x1 + x2 - 1;
restrict 2 * x1 = x2 + x3 , intercept + x4 = 0;
restrict x1 = x2 = x3 = 1;
restrict 2 * x1 - x2;

```

Restricted parameter estimates are computed by introducing a Lagrangian parameter λ for each restriction (Pringle and Rayner 1971). The estimates of these Lagrangian parameters are printed in the “Parameter Estimates” table. If a restriction cannot be applied, its parameter value and degrees of freedom are listed as 0.

The Lagrangian parameter λ measures the sensitivity of the sum of squared errors (SSE) to the restriction. If the restriction is changed by a small amount ϵ , the SSE is changed by $2\lambda\epsilon$.

The t ratio tests the significance of the restrictions. If λ is zero, the restricted estimates are the same as the unrestricted.

Any number of restrictions can be specified on a RESTRICT statement, and any number of RESTRICT statements can be used. The estimates are computed subject to all restrictions specified. However, restrictions should be consistent and not redundant.

NOTE: The RESTRICT statement is not supported for the FIML estimation method.

SRESTRICT Statement

SRESTRICT *equation* , . . . , *equation* ;

The SRESTRICT statement imposes linear restrictions that involve parameters in two or more MODEL statements. The SRESTRICT statement is like the RESTRICT statement but is used to impose restrictions across equations, whereas the RESTRICT statement applies only to parameters in the immediately preceding MODEL statement.

Each restriction is written as a linear equation. Parameters are referred to as *label.variable*, where *label* is the model label and *variable* is the name of the regressor to which the parameter is attached. (If the MODEL statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.) Each variable name used must be a regressor in the indicated MODEL statement. The keyword INTERCEPT is used to refer to intercept parameters.

SRESTRICT statements can be given labels. The labels are used in the printed output to distinguish results for different restrictions. Labels are specified as follows:

label : **SRESTRICT** . . . ;

The following is an example of the use of the SRESTRICT statement, in which the coefficient for the regressor X2 is constrained to be the same in both models.

```
proc syslin data=a 3sls;
  endogenous y1 y2;
  instruments x1 x2;
  model y1 = y2 x1 x2;
  model y2 = y1 x2;
  srestrict y1.x2 = y2.x2;
run;
```

When no equal sign is used, the linear combination is set equal to 0. Thus, the restriction in the preceding example can also be specified as

```
srestrict y1.x2 - y2.x2;
```

Any number of restrictions can be specified on an SRESTRICT statement, and any number of SRESTRICT statements can be used. The estimates are computed subject to all restrictions specified. However, restrictions should be consistent and not redundant.

When a system restriction is requested for a single equation estimation method (such as OLS or 2SLS), PROC SYSLIN produces the restricted estimates by actually using a corresponding system method. For example, when SRESTRICT is specified along with OLS, PROC SYSLIN produces the restricted OLS estimates via a two-step process equivalent to using SUR estimation with the SDIAG option. First, the unrestricted OLS results are produced. Then, the GLS (SUR) estimation with the system restriction is performed, using the diagonal of the covariance matrix of the residuals. When SRESTRICT is specified along with 2SLS, PROC SYSLIN produces the restricted 2SLS estimates via a multistep process equivalent to using 3SLS estimation with the SDIAG option. First, the unrestricted 2SLS results are produced. Then, the GLS (3SLS) estimation with the system restriction is performed, using the diagonal of the covariance matrix of the residuals.

The results of the SRESTRICT statements are printed after the parameter estimates for all the models in the system. The format of the SRESTRICT statement output is the same as the “Parameter Estimates” table. In this output the parameter estimate is the Lagrangian parameter λ used to impose the restriction.

The Lagrangian parameter λ measures the sensitivity of the system sum of square errors to the restriction. The system SSE is the system MSE shown in the printed output multiplied by the degrees of freedom. If the restriction is changed by a small amount ϵ , the system SSE is changed by $2\lambda\epsilon$.

The t ratio tests the significance of the restriction. If λ is zero, the restricted estimates are the same as the unrestricted estimates.

The model degrees of freedom are not adjusted for the cross-model restrictions imposed by SRESTRICT statements.

NOTE: The SRESTRICT statement is not supported for the LIML and the FIML estimation methods.

STEST Statement

STEST *equation* , . . . , *equation* / *options* ;

The STEST statement performs an F test for the joint hypotheses specified in the statement.

The hypothesis is represented in matrix notation as

$$\mathbf{L}\beta = \mathbf{c}$$

and the F test is computed as

$$\frac{(\mathbf{L}b - \mathbf{c})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{L}b - \mathbf{c})}{m\hat{\sigma}^2}$$

where b is the estimate of β , m is the number of restrictions, and $\hat{\sigma}^2$ is the system weighted mean squared error. See the section “Computational Details” on page 1799 for information about the matrix $\mathbf{X}'\mathbf{X}$.

Each hypothesis to be tested is written as a linear equation. Parameters are referred to as *label.variable*, where *label* is the model label and *variable* is the name of the regressor to which the parameter is attached. (If the MODEL statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.) Each variable name used must be a regressor in the indicated MODEL statement. The keyword INTERCEPT is used to refer to intercept parameters.

STEST statements can be given labels. The label is used in the printed output to distinguish different tests. Any number of STEST statements can be specified. Labels are specified as follows:

label : STEST ...;

The following is an example of the STEST statement:

```
proc syslin data=a 3sls;
  endogenous y1 y2;
  instruments x1 x2;
  model y1 = y2 x1 x2;
  model y2 = y1 x2;
  stest y1.x2 = y2.x2;
run;
```

The test performed is exact only for ordinary least squares, given the OLS assumptions of the linear model. For other estimation methods, the *F* test is based on large sample theory and is only approximate in finite samples.

If RESTRICT or SRESTRICT statements are used, the tests computed by the STEST statement are conditional on the restrictions specified. The validity of the tests can be compromised if incorrect restrictions are imposed on the estimates.

The following are examples of STEST statements:

```
stest a.x1 + b.x2 = 1;
stest 2 * b.x2 = c.x3 + c.x4 ,
      a.intercept + b.x2 = 0;
stest a.x1 = c.x2 = b.x3 = 1;
stest 2 * a.x1 - b.x2 = 0;
```

The PRINT option can be specified in the STEST statement after a slash (/):

PRINT

prints intermediate calculations for the hypothesis tests.

NOTE: The STEST statement is not supported for the FIML estimation method.

TEST Statement

TEST *equation* , ... , *equation* / *options* ;

The TEST statement performs F tests of linear hypotheses about the parameters in the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. If more than one equation is specified, the equations are separated by commas.

Variable names must correspond to regressors in the preceding MODEL statement, and each name represents the coefficient of the corresponding regressor. The keyword INTERCEPT is used to refer to the model intercept.

TEST statements can be given labels. The label is used in the printed output to distinguish different tests. Any number of TEST statements can be specified. Labels are specified as follows:

label : TEST ...;

The following is an example of the use of TEST statement, which tests the hypothesis that the coefficients of X1 and X2 are the same:

```
proc syslin data=a;
  model y = x1 x2;
  test x1 = x2;
run;
```

The following statements perform F tests for the hypothesis that the coefficients of X1 and X2 are equal, for the hypothesis that the sum of the X1 and X2 coefficients is twice the intercept, and for the joint hypothesis.

```
proc syslin data=a;
  model y = x1 x2;
  x1eqx2: test x1 = x2;
  sumeq2i: test x1 + x2 = 2 * intercept;
  joint: test x1 = x2, x1 + x2 = 2 * intercept;
run;
```

The following are additional examples of TEST statements:

```
test x1 + x2 = 1;
test x1 = x2 = x3 = 1;
test 2 * x1 = x2 + x3, intercept + x4 = 0;
test 2 * x1 - x2;
```

The TEST statement performs an F test for the joint hypotheses specified. The hypothesis is represented in matrix notation as follows:

$$\mathbf{L}\beta = \mathbf{c}$$

The F test is computed as

$$\frac{(\mathbf{L}\mathbf{b} - \mathbf{c})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{L}\mathbf{b} - \mathbf{c})}{m\hat{\sigma}^2}$$

where b is the estimate of β , m is the number of restrictions, and $\hat{\sigma}^2$ is the model mean squared error. See the section “[Computational Details](#)” on page 1799 for information about the matrix $\mathbf{X}'\mathbf{X}$.

The test performed is exact only for ordinary least squares, given the OLS assumptions of the linear model. For other estimation methods, the F test is based on large sample theory and is only approximate in finite samples.

If RESTRICT or SRESTRICT statements are used, the tests computed by the TEST statement are conditional on the restrictions specified. The validity of the tests can be compromised if incorrect restrictions are imposed on the estimates.

The PRINT option can be specified in the TEST statement after a slash (/):

PRINT

prints intermediate calculations for the hypothesis tests.

NOTE: The TEST statement is not supported for the FIML estimation method.

VAR Statement

VAR *variables* ;

The VAR statement is used to include variables in the crossproducts matrix that are not specified in any MODEL statement. This statement is rarely used with PROC SYSLIN and is used only with the OUTSSCP= option in the PROC SYSLIN statement.

WEIGHT Statement

WEIGHT *variable* ;

The WEIGHT statement is used to perform weighted regression. The WEIGHT statement names a variable in the input data set whose values are relative weights for a weighted least squares fit. If the weight value is proportional to the reciprocal of the variance for each observation, the weighted estimates are the best linear unbiased estimates (BLUE).

Details: SYSLIN Procedure

Input Data Set

PROC SYSLIN does not compute new values for regressors. For example, if you need a lagged variable, you must create it with a DATA step. No values are computed by IDENTITY statements; all values must be in the input data set.

Special TYPE= Input Data Sets

The input data set for most applications of the SYSLIN procedure contains standard rectangular data. However, PROC SYSLIN can also process input data in the form of a crossproducts, covariance, or correlation matrix. Data sets that contain such matrices are identified by values of the TYPE= data set option.

These special kinds of input data sets can be used to save computer time. It takes nk^2 operations, where n is the number of observations and k is the number of variables, to calculate cross products; the regressions are of the order k^3 . When n is in the thousands and k is much smaller, you can save most of the computer time in later runs of PROC SYSLIN by reusing the SSCP matrix rather than recomputing it.

The SYSLIN procedure can process TYPE=CORR, COV, UCORR, UCOV, or SSCP data sets. TYPE=CORR and TYPE=COV data sets, usually created by the CORR procedure, contain means and standard deviations, and correlations or covariances. TYPE=SSCP data sets, usually created in previous runs of PROC SYSLIN, contain sums of squares and cross products. See the *SAS/STAT User's Guide* for more information about special SAS data sets.

When special SAS data sets are read, you must specify the TYPE= data set option. PROC CORR and PROC SYSLIN automatically set the type for output data sets; however, if you create the data set by some other means, you must specify its type with the TYPE= data set option.

When the special data sets are used, the DW (Durbin-Watson test) and PLOT options in the MODEL statement cannot be performed, and the OUTPUT statements are not valid.

Estimation Methods

A brief description of the methods used by the SYSLIN procedure follows. For more information about these methods, see the references at the end of this chapter.

There are two fundamental methods of estimation for simultaneous equations: least squares and maximum likelihood. There are two approaches within each of these categories: single equation methods (also referred to as limited information methods) and system methods (also referred to as

full information methods). System methods take into account cross-equation correlations of the disturbances in estimating parameters, while single equation methods do not.

OLS, 2SLS, MELO, K-class, SUR, ITSUR, 3SLS, and IT3SLS use the least squares method; LIML and FIML use the maximum likelihood method.

OLS, 2SLS, MELO, K-class, and LIML are single equation methods. The system methods are SUR, ITSUR, 3SLS, IT3SLS, and FIML.

Single Equation Estimation Methods

Single equation methods do not take into account correlations of errors across equations. As a result, these estimators are not asymptotically efficient compared to full information methods; however, there are instances in which they may be preferred. (See the section “[Choosing a Method for Simultaneous Equations](#)” on page 1798 for details.)

Let y_i be the dependent endogenous variable in equation i , and X_i and Y_i be the matrices of exogenous and endogenous variables appearing as regressors in the same equation.

The 2SLS method owes its name to the fact that, in a first stage, the instrumental variables are used as regressors to obtain a projected value \hat{Y}_i that is uncorrelated with the residual in equation i . In a second stage, \hat{Y}_i replaces Y_i on the right-hand side to obtain consistent least squares estimators.

Normally, the predetermined variables of the system are used as the instruments. It is possible to use variables other than predetermined variables from your system as instruments; however, the estimation might not be as efficient. For consistent estimates, the instruments must be uncorrelated with the residual and correlated with the endogenous variables.

The LIML method results in consistent estimates that are equal to the 2SLS estimates when an equation is exactly identified. LIML can be viewed as a least-variance ratio estimation or as a maximum likelihood estimation. LIML involves minimizing the ratio $\lambda = (rvar_eq)/(rvar_sys)$, where $rvar_eq$ is the residual variance associated with regressing the weighted endogenous variables on all predetermined variables that appear in that equation, and $rvar_sys$ is the residual variance associated with regressing weighted endogenous variables on all predetermined variables in the system.

The MELO method computes the minimum expected loss estimator. MELO estimators “minimize the posterior expectation of generalized quadratic loss functions for structural coefficients of linear structural models” (Judge et al. 1985, p. 635).

K-class estimators are a class of estimators that depends on a user-specified parameter k . A k value less than 1 is recommended but not required. The parameter k can be deterministic or stochastic, but its probability limit must equal 1 for consistent parameter estimates. When all the predetermined variables are listed as instruments, they include all the other single equation estimators supported by PROC SYSLIN. The instance when some of the predetermined variables are not listed among the instruments is not supported by PROC SYSLIN for the general K-class estimation. However, it is supported for the other methods.

For $k = 1$, the K-class estimator is the 2SLS estimator, while for $k = 0$, the K-class estimator is the OLS estimator. The K-class interpretation of LIML is that $k = \lambda$. Note that k is stochastic in the LIML method, unlike for OLS and 2SLS.

MELO is a Bayesian K-class estimator. It yields estimates that can be expressed as a matrix-weighted average of the OLS and 2SLS estimates. MELO estimators have finite second moments and hence finite risk. Other frequently used K-class estimators might not have finite moments under some commonly encountered circumstances, and hence there can be infinite risk relative to quadratic and other loss functions.

One way of comparing K-class estimators is to note that when $k=1$, the correlation between regressor and the residual is completely corrected for. In all other cases, it is only partially corrected for.

See “[Computational Details](#)” on page 1799 for more details about K-class estimators.

SUR and 3SLS Estimation Methods

SUR might improve the efficiency of parameter estimates when there is contemporaneous correlation of errors across equations. In practice, the contemporaneous correlation matrix is estimated using OLS residuals. Under two sets of circumstances, SUR parameter estimates are the same as those produced by OLS: when there is no contemporaneous correlation of errors across equations (the estimate of the contemporaneous correlation matrix is diagonal) and when the independent variables are the same across equations.

Theoretically, SUR parameter estimates are always at least as efficient as OLS in large samples, provided that your equations are correctly specified. However, in small samples the need to estimate the covariance matrix from the OLS residuals increases the sampling variability of the SUR estimates. This effect can cause SUR to be less efficient than OLS. If the sample size is small and the cross-equation correlations are small, then OLS is preferred to SUR. The consequences of specification error are also more serious with SUR than with OLS.

The 3SLS method combines the ideas of the 2SLS and SUR methods. Like 2SLS, the 3SLS method uses \hat{Y} instead of Y for endogenous regressors, which results in consistent estimates. Like SUR, the 3SLS method takes the cross-equation error correlations into account to improve large sample efficiency. For 3SLS, the 2SLS residuals are used to estimate the cross-equation error covariance matrix.

The SUR and 3SLS methods can be iterated by recomputing the estimate of the cross-equation covariance matrix from the SUR or 3SLS residuals and then computing new SUR or 3SLS estimates based on this updated covariance matrix estimate. Continuing this iteration until convergence produces ITSUR or IT3SLS estimates.

FIML Estimation Method

The FIML estimator is a system generalization of the LIML estimator. The FIML method involves minimizing the determinant of the covariance matrix associated with residuals of the reduced form of the equation system. From a maximum likelihood standpoint, the LIML method involves assuming that the errors are normally distributed and then maximizing the likelihood function subject

to restrictions on a particular equation. FIML is similar, except that the likelihood function is maximized subject to restrictions on all of the parameters in the model, not just those in the equation being estimated.

NOTE: The RESTRICT, SRESTRICT, TEST, and STEST statements are not supported when the FIML method is used.

Choosing a Method for Simultaneous Equations

A number of factors should be taken into account in choosing an estimation method. Although system methods are asymptotically most efficient in the absence of specification error, system methods are more sensitive to specification error than single equation methods.

In practice, models are never perfectly specified. It is a matter of judgment whether the misspecification is serious enough to warrant avoidance of system methods.

Another factor to consider is sample size. With small samples, 2SLS might be preferred to 3SLS. In general, it is difficult to say much about the small sample properties of K-class estimators because the results depend on the regressors used.

LIML and FIML are invariant to the normalization rule imposed but are computationally more expensive than 2SLS or 3SLS.

If the reason for contemporaneous correlation among errors across equations is a common, omitted variable, it is not necessarily best to apply SUR. SUR parameter estimates are more sensitive to specification error than OLS. OLS might produce better parameter estimates under these circumstances. SUR estimates are also affected by the sampling variation of the error covariance matrix. There is some evidence from Monte Carlo studies that SUR is less efficient than OLS in small samples.

ANOVA Table for Instrumental Variables Methods

In the instrumental variables methods (2SLS, LIML, K-class, MELO), first-stage predicted values are substituted for the endogenous regressors. As a result, the regression sum of squares (RSS) and the error sum of squares (ESS) do not sum to the total corrected sum of squares for the dependent variable (TSS). The analysis-of-variance table included in the second-stage results gives these sums of squares and the mean squares that are used for the F test, but this table is not a variance decomposition in the usual sense.

The F test shown in the instrumental variables case is a valid test of the no-regression hypothesis that the true coefficients of all regressors are 0. However, because of the first-stage projection of the regression mean square, this is a Wald-type test statistic, which is asymptotically F but not exactly F -distributed in finite samples. Thus, for small samples the F test is only approximate when instrumental variables are used.

The R-Square Statistics

As explained in the section “ANOVA Table for Instrumental Variables Methods” on page 1798, when instrumental variables are used, the regression sum of squares (RSS) and the error sum of squares (ESS) do not sum to the total corrected sum of squares. In this case, there are several ways that the R^2 statistic can be defined.

The definition of R^2 used by the SYSLIN procedure is

$$R^2 = \frac{RSS}{RSS + ESS}$$

This definition is consistent with the F test of the null hypothesis that the true coefficients of all regressors are zero. However, this R^2 might not be a good measure of the goodness of fit of the model.

System Weighted R-Square and System Weighted Mean Squared Error

The system weighted R^2 , printed for the 3SLS, IT3SLS, SUR, ITSUR, and FIML methods, is computed as follows.

$$R^2 = \mathbf{Y}'\mathbf{WR}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}'\mathbf{WY}/\mathbf{Y}'\mathbf{WY}$$

In this equation, the matrix $\mathbf{X}'\mathbf{X}$ is $\mathbf{R}'\mathbf{WR}$ and \mathbf{W} is the projection matrix of the instruments:

$$\mathbf{W} = \mathbf{S}^{-1} \otimes \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$$

The matrix \mathbf{Z} is the instrument set, \mathbf{R} is the regressor set, and \mathbf{S} is the estimated cross-model covariance matrix.

The system weighted MSE, printed for the 3SLS, IT3SLS, SUR, ITSUR, and FIML methods, is computed as follows:

$$MSE = \frac{1}{tdf}(\mathbf{Y}'\mathbf{WY} - \mathbf{Y}'\mathbf{WR}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}'\mathbf{WY})$$

In this equation, tdf is the sum of the error degrees of freedom for the equations in the system.

Computational Details

This section discusses various computational details.

Computation of Least Squares-Based Estimators

Let the system be composed of G equations and let the i th equation be expressed in this form:

$$y_i = Y_i \beta_i + X_i \gamma_i + \mathbf{u}$$

where

y_i is the vector of observations on the dependent variable

Y_i is the matrix of observations on the endogenous variables included in the equation

β_i is the vector of parameters associated with Y_i

X_i is the matrix of observations on the predetermined variables included in the equation

γ_i is the vector of parameters associated with X_i

\mathbf{u} is a vector of errors

Let $\hat{V}_i = Y_i - \hat{Y}_i$, where \hat{Y}_i is the projection of Y_i onto the space spanned by the instruments matrix \mathbf{Z} .

Let

$$\delta_i = \begin{bmatrix} \beta_i \\ \gamma_i \end{bmatrix}$$

be the vector of parameters associated with both the endogenous and exogenous variables.

The K-class of estimators (Theil 1971) is defined by

$$\hat{\delta}_{i,k} = \begin{bmatrix} Y_i' Y_i - k \hat{V}_i' \hat{V}_i & Y_i' X_i \\ X_i' Y_i & X_i' X_i \end{bmatrix}^{-1} \begin{bmatrix} (Y_i - k \hat{V}_i)' y_i \\ X_i' y_i \end{bmatrix}$$

where k is a user-defined value.

Let

$$\mathbf{R} = [Y_i X_i]$$

and

$$\hat{\mathbf{R}} = [\hat{Y}_i X_i]$$

The 2SLS estimator is defined as

$$\hat{\delta}_{i,2SLS} = [\hat{\mathbf{R}}' \hat{\mathbf{R}}]^{-1} \hat{\mathbf{R}}' y_i$$

Let \mathbf{y} and δ be the vectors obtained by stacking the vectors of dependent variables and parameters for all G equations, and let \mathbf{R} and $\hat{\mathbf{R}}$ be the block diagonal matrices formed by R_i and \hat{R}_i , respectively.

The SUR and ITSUR estimators are defined as

$$\hat{\delta}_{(IT)SUR} = \left[\mathbf{R}' \left(\hat{\Sigma}^{-1} \otimes \mathbf{I} \right) \mathbf{R} \right]^{-1} \mathbf{R}' \left(\hat{\Sigma}^{-1} \otimes \mathbf{I} \right) \mathbf{y}$$

while the 3SLS and IT3SLS estimators are defined as

$$\hat{\delta}_{(IT)3SLS} = \left[\hat{\mathbf{R}}' \left(\hat{\Sigma}^{-1} \otimes \mathbf{I} \right) \hat{\mathbf{R}} \right]^{-1} \hat{\mathbf{R}}' \left(\hat{\Sigma}^{-1} \otimes \mathbf{I} \right) \mathbf{y}$$

where \mathbf{I} is the identity matrix, and $\hat{\Sigma}$ is an estimator of the cross-equation correlation matrix. For 3SLS, $\hat{\Sigma}$ is obtained from the 2SLS estimation, while for SUR it is derived from the OLS estimation. For IT3SLS and ITSUR, it is obtained iteratively from the previous estimation step, until convergence.

Computation of Standard Errors

The VARDEF= option in the PROC SYSLIN statement controls the denominator used in calculating the cross-equation covariance estimates and the parameter standard errors and covariances. The values of the VARDEF= option and the resulting denominator are as follows:

N	uses the number of nonmissing observations.
DF	uses the number of nonmissing observations less the degrees of freedom in the model.
WEIGHT	uses the sum of the observation weights given by the WEIGHTS statement.
WDF	uses the sum of the observation weights given by the WEIGHTS statement less the degrees of freedom in the model.

The VARDEF= option does not affect the model mean squared error, root mean squared error, or R^2 statistics. These statistics are always based on the error degrees of freedom, regardless of the VARDEF= option. The VARDEF= option also does not affect the dependent variable coefficient of variation (CV).

Reduced Form Estimates

The REDUCED option in the PROC SYSLIN statement computes estimates of the reduced form coefficients. The REDUCED option requires that the equation system be square. If there are fewer models than endogenous variables, IDENTITY statements can be used to complete the equation system.

The reduced form coefficients are computed as follows. Represent the equation system, with all endogenous variables moved to the left-hand side of the equations and identities, as

$$\mathbf{B}\mathbf{Y} = \mathbf{\Gamma}\mathbf{X}$$

Here \mathbf{B} is the estimated coefficient matrix for the endogenous variables \mathbf{Y} , and $\mathbf{\Gamma}$ is the estimated coefficient matrix for the exogenous (or predetermined) variables \mathbf{X} .

The system can be solved for \mathbf{Y} as follows, provided \mathbf{B} is square and nonsingular:

$$\mathbf{Y} = \mathbf{B}^{-1}\mathbf{\Gamma}\mathbf{X}$$

The reduced form coefficients are the matrix $\mathbf{B}^{-1}\mathbf{\Gamma}$.

Uncorrelated Errors across Equations

The SDIAG option in the PROC SYSLIN statement computes estimates by assuming uncorrelated errors across equations. As a result, when the SDIAG option is used, the 3SLS estimates are identical to 2SLS estimates, and the SUR estimates are the same as the OLS estimates.

Overidentification Restrictions

The OVERID option in the MODEL statement can be used to test for overidentifying restrictions on parameters of each equation. The null hypothesis is that the predetermined variables that do not appear in any equation have zero coefficients. The alternative hypothesis is that at least one of the assumed zero coefficients is nonzero. The test is approximate and rejects the null hypothesis too frequently for small sample sizes.

The formula for the test is given as follows. Let $y_i = \beta_i \mathbf{Y}_i + \gamma_i \mathbf{Z}_i + e_i$ be the i th equation. \mathbf{Y}_i are the endogenous variables that appear as regressors in the i th equation, and \mathbf{Z}_i are the instrumental variables that appear as regressors in the i th equation. Let N_i be the number of variables in \mathbf{Y}_i and \mathbf{Z}_i .

Let $v_i = y_i - \mathbf{Y}_i \hat{\beta}_i$. Let \mathbf{Z} represent all instrumental variables, T be the total number of observations, and K be the total number of instrumental variables. Define \hat{l} as follows:

$$\hat{l} = \frac{v_i'(\mathbf{I} - \mathbf{Z}_i(\mathbf{Z}_i'\mathbf{Z}_i)^{-1}\mathbf{Z}_i')v_i}{v_i'(\mathbf{I} - \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}')v_i}$$

Then the test statistic

$$\frac{T - K}{K - N_i}(\hat{l} - 1)$$

is distributed approximately as an F with $K - N_i$ and $T - K$ degrees of freedom. See Basmann (1960) for more information.

Fuller's Modification to LIML

The ALPHA= option in the PROC SYSLIN and MODEL statements parameterizes Fuller's modification to LIML. This modification is $k = \gamma - (\alpha/(n - g))$, where α is the value of the ALPHA= option, γ is the LIML k value, n is the number of observations, and g is the number of predetermined variables. Fuller's modification is not used unless the ALPHA= option is specified. See Fuller (1977) for more information.

Missing Values

Observations that have a missing value for any variable in the analysis are excluded from the computations.

OUT= Data Set

The output SAS data set produced by the OUT= option in the PROC SYSLIN statement contains all the variables in the input data set and the variables that contain predicted values and residuals specified by OUTPUT statements.

The residuals are computed as actual values minus predicted values. Predicted values never use lags of other predicted values, as would be desirable for dynamic simulation. For these applications, PROC SIMLIN is available to predict or simulate values from the estimated equations.

OUTEST= Data Set

The OUTEST= option produces a TYPE=EST output SAS data set that contains estimates from the regressions. The variables in the OUTEST= data set are as follows:

BY variables	identifies the BY statement variables that are included in the OUTEST= data set.
TYPE	identifies the estimation type for the observations. The _TYPE_ value INST indicates first-stage regression estimates. Other values indicate the estimation method used: 2SLS indicates two-stage least squares results, 3SLS indicates three-stage least squares results, LIML indicates limited information maximum likelihood results, and so forth. Observations added by IDENTITY statements have the _TYPE_ value IDENTITY.
STATUS	identifies the convergence status of the estimation. _STATUS_ equals 0 when convergence criteria are met. Otherwise, _STATUS_ equals 1 when the estimation converges with a note, 2 when it converges with a warning, or 3 when it fails to converge.
MODEL	identifies the model label. The model label is the label specified in the MODEL statement or the dependent variable name if no label is specified. For first-stage regression estimates, _MODEL_ has the value FIRST.
DEPVAR	identifies the name of the dependent variable for the model.
NAME	identifies the names of the regressors for the rows of the covariance matrix, if the COVOUT option is specified. _NAME_ has a blank value for the parameter estimates observations. The _NAME_ variable is not included in the OUTEST= data set unless the COVOUT option is used to output the covariance of parameter estimates matrix.
SIGMA	contains the root mean squared error for the model, which is an estimate of the standard deviation of the error term. The _SIGMA_ variable contains the same values reported as Root MSE in the printed output.
INTERCEPT	identifies the intercept parameter estimates.
regressors	identifies the regressor variables from all the MODEL statements that are included in the OUTEST= data set. Variables used in IDENTIFY statements are also included in the OUTEST= data set.

The parameter estimates are stored under the names of the regressor variables. The intercept parameters are stored in the variable INTERCEPT. The dependent variable of the model is given a coefficient of -1 . Variables that are not in a model have missing values for the OUTEST= observations for that model.

Some estimation methods require computation of preliminary estimates. All estimates computed are output to the OUTEST= data set. For each BY group and each estimation, the OUTEST= data set contains one observation for each MODEL or IDENTITY statement. Results for different estimations are identified by the `_TYPE_` variable.

For example, consider the following statements:

```
proc syslin data=a outest=est 3sls;
  by b;
  endogenous y1 y2;
  instruments x1-x4;
  model y1 = y2 x1 x2;
  model y2 = y1 x3 x4;
  identity x1 = x3 + x4;
run;
```

The 3SLS method requires both a preliminary 2SLS stage and preliminary first-stage regressions for the endogenous variable. The OUTEST= data set thus contains three different kinds of estimates. The observations for the first-stage regression estimates have the `_TYPE_` value INST. The observations for the 2SLS estimates have the `_TYPE_` value 2SLS. The observations for the final 3SLS estimates have the `_TYPE_` value 3SLS.

Since there are two endogenous variables in this example, there are two first-stage regressions and two `_TYPE_=INST` observations in the OUTEST= data set. Since there are two model statements, there are two OUTEST= observations with `_TYPE_=2SLS` and two observations with `_TYPE_=3SLS`. In addition, the OUTEST= data set contains an observation with the `_TYPE_` value IDENTITY that contains the coefficients specified by the IDENTITY statement. All these observations are repeated for each BY group in the input data set defined by the values of the BY variable B.

When the COVOUT option is specified, the estimated covariance matrix for the parameter estimates is included in the OUTEST= data set. Each observation for parameter estimates is followed by observations that contain the rows of the parameter covariance matrix for that model. The row of the covariance matrix is identified by the variable `_NAME_`. For observations that contain parameter estimates, `_NAME_` is blank. For covariance observations, `_NAME_` contains the regressor name for the row of the covariance matrix and the regressor variables contain the covariances.

See [Example 27.1](#) for an example of the OUTEST= data set.

OUTSSCP= Data Set

The OUTSSCP= option produces a TYPE=SSCP output SAS data set that contains sums of squares and cross products. The data set contains all variables used in the MODEL, IDENTITY, and VAR statements. Observations are identified by the variable `_NAME_`.

The OUTSSCP= data set can be useful when a large number of observations are to be explored in many different SYSLIN runs. The sum-of-squares-and-crossproducts matrix can be saved with the OUTSSCP= option and used as the DATA= data set on subsequent SYSLIN runs. This is much less expensive computationally because PROC SYSLIN never reads the original data again. In the step that creates the OUTSSCP= data set, include in the VAR statement all the variables you expect to use.

Printed Output

The printed output produced by the SYSLIN procedure is as follows:

1. If the SIMPLE option is used, a table of descriptive statistics is printed that shows the sum, mean, sum of squares, variance, and standard deviation for all the variables used in the models.
2. If the FIRST option is specified and an instrumental variables method is used, first-stage regression results are printed. The results show the regression of each endogenous variable on the variables in the INSTRUMENTS list.
3. The results of the second-stage regression are printed for each model. (See the following section “[Printed Output for Each Model](#)” on page 1805 for details.)
4. If a systems method like 3SLS, SUR, or FIML is used, the cross-equation error covariance matrix is printed. This matrix is shown four ways: the covariance matrix itself, the correlation matrix form, the inverse of the correlation matrix, and the inverse of the covariance matrix.
5. If a systems method like 3SLS, SUR, or FIML is used, the system weighted mean squared error and system weighted R^2 statistics are printed. The system weighted MSE and R^2 measure the fit of the joint model obtained by stacking all the models together and performing a single regression with the stacked observations weighted by the inverse of the model error variances.
6. If a systems method like 3SLS, SUR, or FIML is used, the final results are printed for each model.
7. If the REDUCED option is used, the reduced form coefficients are printed. These consist of the structural coefficient matrix for the endogenous variables, the structural coefficient matrix for the exogenous variables, the inverse of the endogenous coefficient matrix, and the reduced form coefficient matrix. The reduced form coefficient matrix is the product of the inverse of the endogenous coefficient matrix and the exogenous structural coefficient matrix.

Printed Output for Each Model

The results printed for each model include the analysis-of-variance table, the “Parameter Estimates” table, and optional items requested by TEST statements or by options in the MODEL statement.

The printed output produced for each model is described in the following.

The analysis-of-variance table includes the following:

- the model degrees of freedom, sum of squares, and mean square
- the error degrees of freedom, sum of squares, and mean square. The error mean square is computed by dividing the error sum of squares by the error degrees of freedom and is not affected by the VARDEF= option.
- the corrected total degrees of freedom and total sum of squares. Note that for instrumental variables methods, the model and error sums of squares do not add to the total sum of squares.
- the F ratio, labeled “F Value,” and its significance, labeled “PROB>F,” for the test of the hypothesis that all the nonintercept parameters are 0
- the root mean squared error. This is the square root of the error mean square.
- the dependent variable mean
- the coefficient of variation (CV) of the dependent variable
- the R^2 statistic. This R^2 is computed consistently with the calculation of the F statistic. It is valid for hypothesis tests but might not be a good measure of fit for models estimated by instrumental variables methods.
- the R^2 statistic adjusted for model degrees of freedom, labeled “Adj R-SQ”

The “Parameter Estimates” table includes the following:

- estimates of parameters for regressors in the model and the Lagrangian parameter for each restriction specified
- a degrees of freedom column labeled DF. Estimated model parameters have 1 degree of freedom. Restrictions have a DF of -1 . Regressors or restrictions dropped from the model due to collinearity have a DF of 0.
- the standard errors of the parameter estimates
- the t statistics, which are the parameter estimates divided by the standard errors
- the significance of the t tests for the hypothesis that the true parameter is 0, labeled “Pr > |t|.” As previously noted, the significance tests are strictly valid in finite samples only for OLS estimates but are asymptotically valid for the other methods.
- the standardized regression coefficients, if the STB option is specified. This is the parameter estimate multiplied by the ratio of the standard deviation of the regressor to the standard deviation of the dependent variable.
- the labels of the regressor variables or restriction labels

In addition to the analysis-of-variance table and the “Parameter Estimates” table, the results printed for each model can include the following:

- If TEST statements are specified, the test results are printed.

- If the DW option is specified, the Durbin-Watson statistic and first-order autocorrelation coefficient are printed.
- If the OVERID option is specified, the results of Basman's test for overidentifying restrictions are printed.
- If the PLOT option is used, plots of residual against each regressor are printed.
- If the COVB or CORRB options are specified, the results for each model also include the covariance or correlation matrix of the parameter estimates. For systems methods like 3SLS and FIML, the COVB and CORB output is printed for the whole system after the output for the last model, instead of separately for each model.

The third-stage output for 3SLS, SUR, IT3SLS, ITSUR, and FIML does not include the analysis-of-variance table. When a systems method is used, the second-stage output does not include the optional output, except for the COVB and CORRB matrices.

ODS Table Names

PROC SYSLIN assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. If the estimation method used is 3SLS, IT3SLS, ITSUR or SUR, you can obtain tables by specifying ODS OUTPUT CorrResiduals, InvCorrResiduals, InvCovResiduals.

Table 27.2 ODS Tables Produced in PROC SYSLIN

ODS Table Name	Description	Option
ANOVA	Summary of the SSE, MSE for the equations	default
AugXPXMat	Model crossproducts	XPX or USSCP
AutoCorrStat	Autocorrelation statistics	DW
ConvergenceStatus	Convergence status	default
CorrB	Correlations of parameters	CORRB
CorrResiduals	Correlations of residuals	
CovB	Covariance of parameters	COVB
CovResiduals	Covariance of residuals	
EndoMat	Endogenous variables	REDUCED
ExogMat	Exogenous variables	REDUCED
FitStatistics	Statistics of fit	default
InvCorrResiduals	Inverse correlations of residuals	
InvCovResiduals	Inverse covariance of residuals	
InvEndoMat	Inverse endogenous variables	REDUCED
InvXPX	$X'X$ inverse for system	I
IterHistory	Iteration printing	ITPRINT
MissingValues	Missing values generated by the program	default
ModelVars	Name and label for the model	default

Table 27.2 (continued)

ODS Table Name	Description	Option
ParameterEstimates	Parameter estimates	default
RedMat	Reduced form	REDUCED
SimpleStatistics	Descriptive statistics	SIMPLE
SSCP	Model crossproducts	XPX or USSCP
TestResults	Test for overidentifying restrictions	
Weight	Weighted model statistics	

ODS Graphics

This section describes the use of ODS for creating graphics with the SYSLIN procedure.

ODS Graph Names

PROC SYSLIN assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when you use ODS. The names are listed in [Table 27.3](#).

To request these graphs, you must specify the ODS GRAPHICS statement.

Table 27.3 ODS Graphics Produced by PROC SYSLIN

ODS Graph Name	Plot Description
ActualByPredicted	Predicted versus actual plot
QQPlot	Q-Q plot of residuals
ResidualHistogram	Histogram of the residuals
ResidualPlot	Residual plot

Examples: SYSLIN Procedure

Example 27.1: Klein's Model I Estimated with LIML and 3SLS

This example uses PROC SYSLIN to estimate the classic Klein Model I. For a discussion of this model, see Theil (1971). The following statements read the data.

```
*-----Klein's Model I-----*
| By I.R. Klein, Economic Fluctuations in the United States, 1921-1941 |
| (1950), NY: John Wiley. A macro-economic model of the U.S. with |
```

```

| three behavioral equations, and several identities. See Theil, p.456. |

```

The following statements estimate the Klein model using the limited information maximum likelihood method. In addition, the parameter estimates are written to a SAS data set with the OUTEST= option.

```

proc syslin data=klein outest=b liml;
  endogenous c p w i x wsum k y;
  instruments klag plag xlag wp g t yr;
  consume: model c = p plag wsum;
  invest:  model i = p plag klag;
  labor:   model w = x xlag yr;
run;

```

```
proc print data=b;
run;
```

The PROC SYSLIN estimates are shown in [Output 27.1.1](#) through [Output 27.1.3](#).

Example 27.2: Grunfeld's Model Estimated with SUR

The following example was used by Zellner in his classic 1962 paper on seemingly unrelated regressions. Different stock prices often move in the same direction at a given point in time. The SUR technique might provide more efficient estimates than OLS in this situation.

The following statements read the data. (The prefix GE stands for General Electric and WH stands for Westinghouse.)

```
*-----Zellner's Seemingly Unrelated Technique-----*
| A. Zellner, "An Efficient Method of Estimating Seemingly |
| Unrelated Regressions and Tests for Aggregation Bias," |
| JASA 57(1962) pp.348-364 |
| |
| J.C.G. Boot, "Investment Demand: an Empirical Contribution |
| to the Aggregation Problem," IER 1(1960) pp.3-30. |
| |
| Y. Grunfeld, "The Determinants of Corporate Investment," |
| Unpublished thesis, Chicago, 1958 |
*-----*

data grunfeld;
  input year ge_i ge_f ge_c wh_i wh_f wh_c;
  label ge_i = 'Gross Investment, GE'
         ge_c = 'Capital Stock Lagged, GE'
         ge_f = 'Value of Outstanding Shares Lagged, GE'
         wh_i = 'Gross Investment, WH'
         wh_c = 'Capital Stock Lagged, WH'
         wh_f = 'Value of Outstanding Shares Lagged, WH';
datalines;

... more lines ...
```

The following statements compute the SUR estimates for the Grunfeld model.

```
proc syslin data=grunfeld sur;
  ge:      model ge_i = ge_f ge_c;
  westing: model wh_i = wh_f wh_c;
run;
```

The PROC SYSLIN output is shown in [Output 27.2.1](#) through [Output 27.2.5](#).

Example 27.3: Illustration of ODS Graphics

This example illustrates the use of ODS graphics. This is a continuation of the section “[Example 27.1: Klein’s Model I Estimated with LIML and 3SLS](#)” on page 1808. These graphical displays are requested by specifying the ODS GRAPHICS statement before running PROC SYSLIN. For information about the graphics available in the SYSLIN procedure, see the section “[ODS Graphics](#)” on page 1808.

The following statements show how to generate ODS graphics plots with the SYSLIN procedure. The plots of residuals for each one of the equations in the model are displayed in [Figure 27.3.1](#) through [Figure 27.3.3](#).

Example 28.2: Inferring a Date Interval	1845
Example 28.3: Examining Multiple BY Groups	1846

Overview: TIMEID Procedure

The TIMEID procedure evaluates a variable in an input data set for its suitability as a time ID variable in SAS procedures and solutions that are used for time series analysis. PROC TIMEID assesses how well a time interval specification fits SAS date or datetime values, or observation numbers used to index a time series. The time interval used in this analysis can be either specified explicitly as input to PROC TIMEID or inferred by the procedure based on values of the time ID variable. The TIMEID procedure produces diagnostic information in the form of data sets and ODS tabular and plotted output. These diagnostic results summarize characteristics of the time ID variable that can help determine its use as an index in other time series procedures and solutions.

PROC TIMEID is intended for use as a tool to either identify the time interval of a variable or prepare problematic data sets for use in subsequent time series analyses. In particular, this procedure can

be used to investigate inconsistencies between time ID values and the ID statement options used in other SAS procedures and solutions.

Getting Started: TIMEID Procedure

When a data set contains a time ID variable with corrupted, missing, or duplicate values, PROC TIMEID can help isolate and identify these problematic observations. For a data set with a small number of ID variable anomalies and a known time interval, a graphical depiction of the problem areas can be created using the following statements:

```
proc timeid data=<input-dataset> plot=values;
  id <time-ID-variable> interval=<frequency>;
run;
```

For larger data sets whose quality is unknown, it can be useful to get a general overview of the relative number of observations with problematic time ID values. The following statements graphically summarize the prevalence of anomalous time ID values:

```
proc timeid data=<input-dataset> plot=(intervalcounts offsets spans);
  id <time-ID-variable> interval=<frequency>;
run;
```

When prior knowledge of the time interval that separates observations is incomplete, PROC TIMEID can be used to infer the interval by omitting the INTERVAL= option from the ID statement as in the following statements:

```
proc timeid data=<input-dataset> outinterval=<output-dataset>;
  id <time-ID-variable>;
run;
```

Syntax: TIMEID Procedure

The TIMEID procedure uses the following statements:

```
PROC TIMEID options ;
  BY variables ;
  ID variable <options> ;
```

Functional Summary

The statements and options that control the TIMEID procedure are summarized in Table 28.1.

Table 28.1 Syntax Summary

Description	Statement	Option
Statements		
Specifies data sets and options	PROC TIMEID	
Specifies BY-group processing	BY	
Specifies the time ID variable	ID	
Data Set Options		
Specifies the input data set	PROC TIMEID	DATA=
Specifies the maximum number of ID values to analyze	PROC TIMEID	NBYOBS=
Specifies the output frequency count data set	PROC TIMEID	OUTFREQ=
Specifies the output interval data set	PROC TIMEID	OUTINTERVAL=
Specifies the detailed output interval data set	PROC TIMEID	OUTINTERVALDETAILS=
Time ID Options		
Specifies the interval alignment	ID	ALIGN=
Specifies that duplicate time ID values can be present in DATA= data set	ID	DUPLICATES
Specifies the time interval between observations	ID	INTERVAL=
Specifies that time ID variable values are not sorted	ID	NOTSORTED
Printing and Plotting Options		
Specifies the time ID format	ID	FORMAT=
Specifies the types of graphical output	PROC TIMEID	PLOT=
Specifies the types of printed output	PROC TIMEID	PRINT=
Miscellaneous Options		
Limits error and warning messages	PROC TIMEID	MAXERROR=

PROC TIMEID Statement

PROC TIMEID *options* ;

The following options can be used in the PROC TIMEID statement:

DATA=SAS-data-set

names the SAS data set that contains the input data for the procedure. If the DATA= option is not specified, the most recently created SAS data set is used.

MAXERROR=number

limits the number of warning and error messages produced during the execution of the procedure to the specified value. The default is MAXERRORS=50. This option is particularly useful in BY-group processing where it can be used to suppress recurring messages.

NBYOBS=number

limits the number of observations that are used to analyze the time ID variable. The NBYOBS= option should be used instead of the OBS= data set option when BY variables are specified. The NBYOBS= option excludes observations from incomplete BY groups in the analysis. This option guarantees that any truncation of the DATA= data set occurs at a BY-group boundary. Only BY groups that are completely contained within the first *number* of observations are processed. When the NBYOBS= option is omitted, all observations are processed.

OUTFREQ=SAS-data-set

names the output data set to contain the frequency counts of each unique value of the time ID variable. The frequency counts are performed on time ID values that are recorded in the DATA= data set. The time ID values are not aligned with respect to an interval prior to computation of the frequency counts. See the section “[OUTFREQ= Data Set](#)” on page 1834 for details.

OUTINTERVAL=SAS-data-set

names the output data set to contain the time ID interval information that is summarized across all BY groups in the DATA= data set. See the section “[OUTINTERVAL= Data Set](#)” on page 1834 for details.

OUTINTERVALDETAILS=SAS-data-set

names the output data set to contain the time ID interval information for each BY group. See the section “[OUTINTERVALDETAILS= Data Set](#)” on page 1835 for details.

PLOT(*global-option*)=*request-option* | (*request-options*)

specifies the graphical output desired. By default, the TIMEID procedure produces no graphical output. The following *global-options* are available:

UNPACK | UNPACKPANELS suppresses paneling.

By default, multiple plots can appear in some output panels. Specify UNPACKPANELS to get each plot in a separate panel. The following plot *request-options* are available:

COUNTS INTCNTS INTERVALCOUNTS	plots a histogram of the time ID interval counts.
OFFSETS	plots a histogram of the time offsets for the time ID values.
PERIODS SPANS	plots a histogram of the spans between adjacent time ID values.
VALUES	plots a panel of the counts, offsets, and spans for each of the time ID values.
ALL	is equivalent to specifying PLOT=(INTERVALCOUNTS SPANS OFFSETS VALUES).

See the section “[Time ID Diagnostics](#)” on page 1831 for details.

PRINT=option | (options)

specifies the printed output desired. By default, the TIMEID procedure produces no printed output. The following printing options are available:

COUNTS INTCNTS INTERVALCOUNTS	prints a table that contains the counts of time ID values per interval.
INTERVAL	prints a summary of information about the time interval.
OFFSETS	prints a table that contains the time offsets for the time ID values.
PERIODS SPANS	prints tables that contain statistics on the spans between adjacent time ID values.
VALUES	prints tables that contain offset span and count information for the time ID values.
ALL	is equivalent to specifying PRINT=(INTERVALCOUNTS SPANS INTERVAL OFFSETS VALUES).

See the section “[Time ID Diagnostics](#)” on page 1831 for details.

BY Statement

BY variables ;

A BY statement can be used with PROC TIMEID to obtain separate analyses for groups of observations defined by the BY variables.

ID Statement

ID variable < options > ;

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date or datetime values. The ID statement options specify how the time ID values are spaced and aligned relative to a SAS date or datetime interval. The INTERVAL= option specifies the fundamental spacing that is used as the basis for counting intervals, offsets, and spans in the data. Specification of the ID variable in an ID statement is required.

ALIGN=alignment

specifies the alignment of the identifying SAS date or datetime that is used to represent intervals. The value of the ALIGN= option is used in the analysis of the time ID variable. The ALIGN= option accepts the following values: BEGINNING | BEG | B, MIDDLE | MID | M, ENDING | END | E, and INFER. For example, ALIGN=BEGIN specifies that the identifying date for the interval is the beginning date in the interval. If the ALIGN= option is not specified, then the default alignment is BEGIN. ALIGN=INFER specifies that the alignment of values within time intervals be inferred from the time ID values.

DUPLICATES

specifies that multiple observations in the DATA= data set can fall within the same time interval as defined by the time ID variable. When this option is omitted and multiple time ID values are encountered in a single time interval, error messages are written to the SAS log.

FORMAT=format

specifies the SAS format used for time ID values in the data sets and in printed and plotted output that is generated by PROC TIMEID. If the FORMAT= option is not specified, the format applied to the input time ID variable is used. If neither of these formats is specified, the format is inferred from the INTERVAL= option.

INTERVAL=interval

specifies the proposed time interval and shift that describe the time ID values in the input data set. See Chapter 4, “Date Intervals, Formats, and Functions,” for more information about the intervals that can be specified. See the section “Time ID Diagnostics” on page 1831 for more information about how the INTERVAL= option determines the nature of diagnostic information reported by the TIMEID procedure.

If no interval is specified, the procedure attempts to infer an interval from the input time ID values. See the section “Inferring Time Intervals and Alignments” on page 1833 for details about how the time interval is inferred.

NOTSORTED

specifies that the observations in the DATA= data set are not sorted by the time ID variable. When this option is omitted, error messages are generated for time ID values that are not sorted in ascending order.

Details: TIMEID Procedure

Time ID Diagnostics

For a specified time interval, PROC TIMEID decomposes the raw time ID values in an input data set into the following three quantities, whose values are represented by nonnegative integers at each unique time ID value in the input series:

interval counts the number of observations that share each time interval in the data set.

offsets the numerical difference between a time ID value and the aligned value for that time interval. The unit of measure used to express this distance is days for date values and seconds for datetime values. The offset is computed for each time ID value, t_i , by using the following SAS expression:

$$\text{offset}_i = t_i - \text{INTNX}(\text{interval}, t_i, 0, \text{alignment})$$

spans the number of intervals between each time ID value and the previous time ID value. The spans value is equivalent to the number returned by the following SAS expression:

$$\text{spans}_i = \text{INTCK}(\text{interval}, t_{i-1}, t_i)$$

Diagnostic Output Representation

The TIMEID procedure produces time ID diagnostics as both time-ID-based and count-based frequency distributions to expose many of the possible problems that can occur in a time ID variable. The time-ID-based frequency distributions that are generated with the PLOT= option provide a detailed view of time ID values that can isolate problems with specific ID values. [Figure 28.1](#) shows a time series that has a span of 10 observations in a weekday series based on the results of the PLOT=(VALUES SPANS) option. The single large bar in the spans plot shows where data are omitted.

Figure 28.1 Time ID Decomposition

The count-based frequency distributions summarize features of the time ID variable. Individual printed and plotted outputs are available to describe the distribution of the number of spans, offsets, and interval counts that occur in the time ID variable. [Figure 28.2](#) illustrates a count-based frequency distribution of the spans within the weekday series.

Figure 28.2 Span Count Distribution

The large bar at the span of 1 shows that most of the observations are correctly separated by one interval. The bar at 11 indicates that one observation is separated by 11 intervals from the preceding value of the time ID variable. This further illustrates a span of 10 omitted observations.

Inferring Time Intervals and Alignments

When the `INTERVAL=` option is not specified in the `ID` statement, a time interval is inferred from the time ID values in the input data set. The technique used to infer a time interval involves searching for the interval that fits the greatest number of time ID values. First, time ID values are sampled from the input data set to generate a set of candidate intervals. Then the candidate interval that is consistent with greatest number of time ID values is chosen to represent the time series.

When the `ALIGN=INFER` option is specified, the convention that is used to specify time interval alignment is inferred from the time ID variable values by using a similar technique. When both the time interval and its alignment are to be inferred, each of the possible alignments, `BEGIN`, `MIDDLE`, and `END`, are considered in the search. Precedence in the search is given to intervals with the `BEGIN` alignment.

Data Set Output

The TIMEID procedure creates the OUTFREQ=, OUTINTERVAL=, and OUTINTERVALDETAILS= data sets. The OUTFREQ= and OUTINTERVALDETAILS= data sets contain the variables that are specified in the BY statement along with variables that characterize the time ID values. The OUTINTERVAL= option creates a data set without BY variables. The information in this data set summarizes time ID diagnostic information across all BY groups in the DATA= data set.

OUTFREQ= Data Set

The OUTFREQ= data set contains a single observation for each value of the time ID variable in the input data set for each BY group. Additionally, the following variables are written to the OUTFREQ= data set:

<code>_COUNT_</code>	number of the occurrences of the time ID value
<code>_PERCENT_</code>	percentage of all time ID values

OUTINTERVAL= Data Set

The OUTINTERVAL= data set contains information that is similar to the variables written to the OUTINTERVALDETAILS= data set; however, the OUTINTERVAL= data set summarizes the information across all BY groups into a single observation. The following variables are written to the OUTINTERVAL= data set:

TIMEID	time ID variable
START	smallest time ID value
END	largest time ID value
STARTSHARED	largest starting time ID value
ENDSHARED	smallest ending time ID value
NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
NBY	number of BY groups
NINVALID	number of invalid observations
STATUS	status flag that indicates whether the requested analyses were successful:
0	The analysis completed successfully.
4000	Inference of a time interval from the data set failed.
5000	Diagnosis of the DATA= data set for the specified time interval failed.

MSG	a message that provides further details when the STATUS variable is not zero
INTERVAL	time interval that is specified or recommended
INTNAME	time interval base name that is specified or recommended
MULTIPLIER	time interval multiplier that is specified or recommended
SHIFT	time interval shift that is specified or recommended
ALIGNMENT	time interval alignment that is specified or recommended
SEASONALITY	seasonality determined from specified or recommended time interval
TOTALSEASONCYCLES	total number of seasonal cycles spanned by all the observations
SEASONCYCLESSHARED	number of seasonal cycles that are shared among all BY groups
FORMAT	format of the time ID variable

OUTINTERVALDETAILS= Data Set

The OUTINTERVALDETAILS= data set contains statistics about the time interval that is specified in the ID statement or inferred from the time ID values for each BY group. The following variables represent these statistics:

TIMEID	time ID variable name
START	starting time ID value
END	ending time ID value
NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
NINVALID	number of invalid observations
NINTCNTS	number of distinct interval count values
PCTINTCNTS	percentage of interval counts greater than one
MININTCNT	minimum of interval counts
MAXINTCNT	maximum of interval counts
MEANINTCNT	mean of interval counts
STDINTCNT	standard deviation of interval counts
MEDINTCNT	median of interval counts
NOFFSETS	number of time ID offset
PCTOFFSETS	percentage of time ID offset
MINOFFSET	minimum of time ID offsets
MAXOFFSET	maximum of time ID offsets
MEANOFFSET	mean of time ID offsets
STDOFFSET	standard deviation of time ID offsets

MEDOFFSET	median of time ID offsets
NSPANS	number of spans between time ID values
PCTSPANS	percentage of spans between time ID values
MINSPAN	maximum of spans between time ID values
MAXSPAN	minimum of spans between time ID values
MEANSPAN	mean of spans between time ID values
STDSPAN	standard deviation of spans between time ID values
MEDSPAN	median of spans between time ID values
STATUS	status flag that indicates whether the requested analyses were successful:
	0 The analysis completed successfully.
	4000 Inference of a time interval from the data set failed .
	5000 Diagnosis of the DATA= data set for specified time interval failed.
MSG	a message that provides further details when the STATUS variable is not zero
INTERVAL	time interval specified or recommended
INTNAME	time interval base name specified or recommended
MULTIPLIER	time interval multiplier specified or recommended
SHIFT	time interval shift specified or recommended
ALIGNMENT	time interval alignment specified or recommended
SEASONALITY	seasonality determined from specified or recommended time interval
NSEASONCYCLES	number of seasonal cycles spanned by the time ID values
FORMAT	format of the time ID variable

Printed Tabular Output

The TIMEID procedure optionally produces printed output by using the Output Delivery System (ODS). By default, the procedure produces no printed output. The appearance of the printed tabular output is controlled by the PRINT= option in the PROC TIMEID statement.

Table 28.2 relates the PRINT= options to the names of the ODS tables.

Table 28.2 ODS Tables Produced in PROC TIMEID

ODS Name	Description	PRINT= Option
DataSet	Information about the input data set	ALL
Decomposition	Time ID counts, offsets, and spans	VALUES

Table 28.2 (continued)

ODS Table Name	Description	PRINT= Option
Interval	Information about the time interval	INTERVAL
IntervalCountsComponent	Frequency distribution of interval counts	INTERVALCOUNTS
IntervalCountsStatistics	Statistics on interval count frequency distribution	INTERVALCOUNTS
OffsetsComponent	Frequency distribution of offsets	OFFSETS
OffsetStatistics	Statistics on offset frequency distribution	OFFSETS
SpansComponent	Frequency distribution of spans	SPANS
SpanStatistics	Statistics on the span frequency distribution	SPANS
Values	Time ID value counts	VALUES
ValueSummary	Summary of the number of valid observations	VALUES

ODS Graphics

The TIMEID procedure uses ODS Graphics to produce plotted output as specified by the PLOT= option. Table 28.3 relates the PLOT= options to the names of the ODS Graphics objects.

Table 28.3 ODS Graphics Produced by the PLOT= Option in PROC TIMEID

ODS Graph Name	Plot Description	PLOT= Option
DecompositionPlot	Panel of spans, offsets, and counts for each time interval	VALUES

Examples: TIMEID Procedure

Example 28.1: Examining a Weekly Time ID Variable

This example illustrates how problems in a weekly time series can be visualized and quantified using the TIMEID procedure's diagnostic capabilities.

The following DATA step creates a data set that contains time values spaced in three week intervals where some weeks have been skipped or duplicated and some have been recorded on different weekdays.

```
data triweek;
  format date date.;
  input date : date. @@;
datalines;
28DEC48 18JAN49 08FEB49 01MAR49 22MAR49 12APR49 03MAY49 24MAY49
17JUN49 05JUL49 26JUL49 16AUG49 06SEP49 27SEP49 18OCT49 08NOV49

... more lines ...
```

The following TIMEID procedure statements generate an ODS display of the time series that characterizes interval counts, offsets, and spans in the time ID variable.

```
proc timeid data=triweek print=all plot=all;
  id date interval=week3;
run;
```

The Time ID decomposition listing and plot shown in [Output 28.1.1](#) and [Output 28.1.2](#) summarize how well the WEEK3 interval fits the time ID values by showing the number of counts, offsets, and spans for each time interval that is represented by the DATE variable. The listing in [Output 28.1.1](#) has been truncated to include only the first 10 observations. The Time ID plots in [Output 28.1.2](#) indicate that there are duplicated time ID values for a three-week time interval in the Counts plot. The duplicated time intervals have a Count value of 2. The Offsets plot shows which days in the 21 day cycle have been used to record each time interval in the series. The Spans plot records values of 2 for six time intervals where no observations were recorded in the previous interval. The three component plots are histogram summaries of the diagnostic quantities plotted against individual intervals in the decomposition plots. The component plots can be useful in diagnosing time series that contain many time intervals.

Output 28.1.1 Time ID Decomposition Listing

Value Index	Time Component			Interval Count
	date	Offset	Span	
1	Sun, 12 Dec 1948	16	.	1
2	Sun, 2 Jan 1949	16	1	1
3	Sun, 23 Jan 1949	16	1	1
4	Sun, 13 Feb 1949	16	1	1
5	Sun, 6 Mar 1949	16	1	1
6	Sun, 27 Mar 1949	16	1	1
7	Sun, 17 Apr 1949	16	1	1
8	Sun, 8 May 1949	16	1	1
9	Sun, 29 May 1949	19	1	1
10	Sun, 19 Jun 1949	16	1	1

Output 28.1.2 Time ID Decomposition Plot

Output 28.1.3 and Output 28.1.4 describe the distribution of counts of duplicated WEEK3 intervals in the TriWeek data set. For this data set there are 134 intervals that contain one DATE value, and 10 intervals that contain two DATE values.

Output 28.1.3 Time ID Interval Counts Listings

The TIMEID Procedure				
Component				
Value Index	Interval Count	Frequency	Percentage	
1	1	134	93.055556	
2	2	10	6.944444	
Statistics Summary				
Minimum	Maximum	Mean	Standard Deviation	
1	2	1.0694444	1.1004981	

Output 28.1.4 Time ID Interval Counts Histogram

The offsets diagnostics [Output 28.1.5](#) and [Output 28.1.6](#) show the distribution of days in the 21-day WEEK3 interval used to record the time intervals in the series. The observations in the TriWeek data set represent intervals with five different offsets from the beginning of the WEEK3 interval: 0, 16, 18, 19 and 20. The high prevalence of intervals with offset 16 indicates that the TriWeek data set would be represented better using the WEEK3.17 interval.

Output 28.1.5 Time ID Offsets Listings

The TIMEID Procedure				
Component				
Value Index	Offset	Frequency	Percentage	
1	0	1	0.694444	
2	16	138	95.833333	
3	18	1	0.694444	
4	19	1	0.694444	
5	20	3	2.083333	
Statistics Summary				
Minimum	Maximum	Mean	Standard Deviation	
0	20	16.006944	1.7006205	

Output 28.1.6 Time ID Offsets Histogram

The span diagnostics [Output 28.1.7](#) and [Output 28.1.8](#) show the distribution of the span sizes between successive DATE values. The TriWeek data set has three different span sizes of widths 0, 1 and 2. Here one span corresponds to the width of a WEEK3 interval.

Output 28.1.7 Time ID Span Listings

The TIMEID Procedure				
Component

Output 28.1.10 Unaligned Time ID Histogram

Example 28.2: Inferring a Date Interval

This example illustrates how a time ID variable can be inferred from a data set when a sufficient number of observations are present.

```

data workdays;
  format day weekdate.;
  input day : date. @@;
  datalines;
01AUG09 06AUG09 11AUG09 14AUG09 19AUG09 22AUG09
27AUG09 01SEP09 04SEP09 09SEP09 12SEP09 17SEP09
;

proc timeid data=workdays print=interval;
  id day;
run;

```

The 12 observations in the WorkDays data set are enough to determine that the DAY time ID variable is represented by the WEEKDAY12W3 interval. The WEEKDAY12W3 interval corresponds to every third day of the week excluding Sundays and Mondays. Characteristics of this interval are shown in [Output 28.2.1](#).

Output 28.2.1 Inferred Time Interval Information

The TIMEID Procedure	
Time Interval Analysis Summary	
Time ID Variable	day
Time Interval	WEEKDAY12W3
Base Name	WEEKDAY
Multiplier	3
Shift	0
Length of Seasonal Cycle	5
Time ID Format	WEEKDATE
Start	Saturday, August 1, 2009
End	Thursday, September 17, 2009

Example 28.3: Examining Multiple BY Groups

This example illustrates how a time ID variable can be examined independently over each BY group and summarized over all observations in the DATA= data set.

```
data bygroups;
  format tid date.;
  input tid : date. by @@;
datalines;

  ... more lines ...
```

The following TIMEID procedure statements generate two data sets that summarize a data set with four BY groups.

```
proc timeid data=bygroups outintervaldetails=int outinterval=intsum;
  id tid;
  by by;
run;
```

The summarized information in [Output 28.3.1](#) shows that BY groups 2, 3, and 4 in the ByGroups data set contain some duplicate values and spans, and group 1 conforms exactly to the WEEKDAY17W interval. This listing also shows that the date ranges in these two BY groups start and end on different days and that they overlap between December 7, 2009, and December 28, 2009.

Output 28.3.1 Selected Variables in the Combined OUTINTERVALDETAILS= OUTINTERVAL= Data Sets

Overview: TIMESERIES Procedure

The TIMESERIES procedure analyzes time-stamped transactional data with respect to time and accumulates the data into a time series format. The procedure can perform trend and seasonal analysis on the transactions. After the transactional data are accumulated, time domain and frequency domain analysis can be performed on the accumulated time series.

For seasonal analysis of the transaction data, various statistics can be computed for each season. For trend analysis of the transaction data, various statistics can be computed for each time period. The analysis is similar to applying the MEANS procedure of Base SAS software to each season or time period of concern.

After the transactional data are accumulated to form a time series and any missing values are interpreted, the accumulated time series can be functionally transformed using log, square root, logistic, or Box-Cox transformations. The time series can be further transformed using simple and/or seasonal differencing. After functional and difference transformations have been applied, the accumulated and transformed time series can be stored in an output data set. This working time series can then be analyzed further using various time series analysis techniques provided by this procedure or other SAS/ETS procedures.

Time series analyses performed by the TIMESERIES procedure include:

- descriptive (global) statistics
- seasonal decomposition/adjustment analysis
- correlation analysis
- cross-correlation analysis
- spectral analysis

All results of the transactional or time series analysis can be stored in output data sets or printed using the Output Delivery System (ODS).

The TIMESERIES procedure can process large amounts of time-stamped transactional data. Therefore, the analysis results are useful for large-scale time series analysis or (temporal) data mining. All of the results can be stored in output data sets in either a time series format (default) or in a coordinate format (transposed). The time series format is useful for preparing the data for subsequent analysis with other SAS/ETS procedures. For example, the working time series can be further analyzed, modeled, and forecast with other SAS/ETS procedures. The coordinate format is useful when using this procedure with SAS/STAT procedures or SAS Enterprise Miner. For example, clustering time-stamped transactional data can be achieved by using the results of this procedure with the clustering procedures of SAS/STAT and the nodes of SAS Enterprise Miner.

The EXPAND procedure can be used for the frequency conversion and transformations of time series output from this procedure.

Getting Started: TIMESERIES Procedure

This section outlines the use of the TIMESERIES procedure and gives a cursory description of some of the analysis techniques that can be performed on time-stamped transactional data.

Given an input data set that contains numerous transaction variables recorded over time at no specific frequency, the TIMESERIES procedure can form time series as follows:

```
PROC TIMESERIES DATA=<input-data-set>
                OUT=<output-data-set>;
  ID <time-ID-variable> INTERVAL=<frequency>
                ACCUMULATE=<statistic>;
  VAR <time-series-variables>;
RUN;
```

The TIMESERIES procedure forms time series from the input time-stamped transactional data. It can provide results in output data sets or in other output formats by using the Output Delivery System (ODS).

Time-stamped transactional data are often recorded at no fixed interval. Analysts often want to use time series analysis techniques that require fixed-time intervals. Therefore, the transactional data must be accumulated to form a fixed-interval time series.

Suppose that a bank wants to analyze the transactions associated with each of its customers over time. Further, suppose that the data set WORK.TRANSACTIONS contains four variables that are related to these transactions: CUSTOMER, DATE, WITHDRAWAL, and DEPOSITS. The following examples illustrate possible ways to analyze these transactions by using the TIMESERIES procedure.

To accumulate the time-stamped transactional data to form a daily time series based on the accumulated daily totals of each type of transaction (WITHDRAWALS and DEPOSITS), the following TIMESERIES procedure statements can be used:

```

proc timeseries data=transactions
                out=timeseries;
  by customer;
  id date interval=day accumulate=total;
  var withdrawals deposits;
run;

```

The OUT=TIMESERIES option specifies that the resulting time series data for each customer is to be stored in the data set WORK.TIMESERIES. The INTERVAL=DAY option specifies that the transactions are to be accumulated on a daily basis. The ACCUMULATE=TOTAL option specifies that the sum of the transactions is to be calculated. After the transactional data is accumulated into a time series format, many of the procedures provided with SAS/ETS software can be used to analyze the resulting time series data.

For example, the ARIMA procedure can be used to model and forecast each customer's withdrawal data by using an ARIMA(0,1,1)(0,1,1)_s model (where the number of seasons is $s=7$ days in a week) using the following statements:

```

proc arima data=timeseries;
  identify var=withdrawals(1,7) noprint;
  estimate q=(1)(7) outest=estimates noprint;
  forecast id=date interval=day out=forecasts;
quit;

```

The OUTEST=ESTIMATES data set contains the parameter estimates of the model specified. The OUT=FORECASTS data set contains forecasts based on the model specified. See the SAS/ETS ARIMA procedure for more detail.

A single set of transactions can be very large and must be summarized in order to analyze them effectively. Analysts often want to examine transactional data for trends and seasonal variation. To analyze transactional data for trends and seasonality, statistics must be computed for each time period and season of concern. For each observation, the time period and season must be determined and the data must be analyzed based on this determination.

The following statements illustrate how to use the TIMESERIES procedure to perform trend and seasonal analysis of time-stamped transactional data.

```

proc timeseries data=transactions out=out
                outseason=season outtrend=trend;
  by customer;
  id date interval=day accumulate=total;
  var withdrawals deposits;
run;

```

Since the INTERVAL=DAY option is specified, the length of the seasonal cycle is seven (7) where the first season is Sunday and the last season is Saturday. The output data set specified by the OUTSEASON=SEASON option contains the seasonal statistics for each day of the week by each customer. The output data set specified by the OUTTREND=TREND option contains the trend statistics for each day of the calendar by each customer.

Often it is desired to seasonally decompose into seasonal, trend, cycle, and irregular components or to seasonally adjust a time series. The following techniques describe how the changing seasons influence the time series.

The following statements illustrate how to use the TIMESERIES procedure to perform seasonal adjustment/decomposition analysis of time-stamped transactional data.

```
proc timeseries data=transactions
                out=out
                outdecomp=decompose;
  by customer;
  id date interval=day accumulate=total;
  var withdrawals deposits;
run;
```

The output data set specified by the OUTDECOMP=DECOMPOSE data set contains the decomposed/adjusted time series for each customer.

A single time series can be very large. Often, a time series must be summarized with respect to time lags in order to be efficiently analyzed using time domain techniques. These techniques help describe how a current observation is related to the past observations with respect to the time (season) lag.

The following statements illustrate how to use the TIMESERIES procedure to perform time domain analysis of time-stamped transactional data.

```
proc timeseries data=transactions
                out=out
                outcorr=timedomain;
  by customer;
  id date interval=day accumulate=total;
  var withdrawals deposits;
run;
```

The output data set specified by the OUTCORR=TIMEDOMAIN data set contains the time domain statistics, such as sample autocorrelations and partial autocorrelations, by each customer.

Sometimes time series data contain underlying patterns that can be identified using spectral analysis techniques. Two kinds of spectral analyses on univariate data can be performed using the TIMESERIES procedure. They are singular spectrum analysis and Fourier spectral analysis.

Singular spectrum analysis (SSA) is a technique for decomposing a time series into additive components and categorizing these components based on the magnitudes of their contributions. SSA uses a single parameter, the window length, to quantify patterns in a time series without relying on prior information about the series' structure. The window length represents the maximum lag that is considered in the analysis, and it corresponds to the dimensionality of the principle components analysis (PCA) on which SSA is based. The components are combined into groups to categorize their roles in the SSA decomposition.

Fourier spectral analysis decomposes a time series into a sum of harmonics. In the discrete Fourier transform, the contribution of components at evenly spaced frequencies are quantified in a periodogram and summarized in spectral density estimates.

The following statements illustrate how to use the TIMESERIES procedure to analyze time-stamped transactional data without prior information about the series' structure.

```
proc timeseries data=transactions
                outssa=ssa
                outspectra=spectra;
  by customer;
  id date interval=day accumulate=total;
  var withdrawals deposits;
run;
```

The output data set specified by the OUTSSA=SSA data set contains a singular spectrum analysis of the withdrawals and deposits data. The data set specified by OUTSPECTRA=SPECTRA contains a Fourier spectral decomposition of the same data.

By default, the TIMESERIES procedure produces no printed output.

Syntax: TIMESERIES Procedure

The TIMESERIES Procedure uses the following statements:

```

PROC TIMESERIES Statement

PROC TIMESERIES *options* ;

The following options can be used in the PROC TIMESERIES statement:

DATA= *SAS-data-set*

names the SAS data set that contains the input data for the procedure to create the time series. If the DATA= option is not specified, the most recently created SAS data set is used.

CROSSPLOTS= *option* | (*options*)

specifies the cross-variable graphical output desired. By default, the TIMESERIES procedure produces no graphical output. The following plotting options are available:

SERIES plots the time series (OUT= data set).

CCF plots the cross-correlation functions (OUTCROSSCORR= data set).

ALL same as PLOTS=(SERIES CCF).

For example, CROSSPLOTS=SERIES plots the two time series. The CROSSPLOTS= option produces graphical output for these results by using the Output Delivery System (ODS). The CROSSPLOTS= option produces results similar to the data sets listed in parentheses next to the preceding options.

MAXERROR= *number*

limits the number of warning and error messages that are produced during the execution of the

procedure to the specified value. The default is MAXERRORS=50. This option is particularly useful in BY-group processing where it can be used to suppress the recurring messages.

OUT= *SAS-data-set*

names the output data set to contain the time series variables specified in the subsequent VAR and CROSSVAR statements. If BY variables are specified, they are also included in the OUT= data set. If an ID variable is specified, it is also included in the OUT= data set. The values are accumulated based on the ID statement INTERVAL= or the ACCUMULATE= option or both. The OUT= data set is particularly useful when you want to further analyze, model, or forecast the resulting time series with other SAS/ETS procedures.

OUTCORR= *SAS-data-set*

names the output data set to contain the univariate time domain statistics.

OUTCROSSCORR= *SAS-data-set*

names the output data set to contain the cross-correlation statistics.

OUTDECOMP= *SAS-data-set*

names the output data set to contain the decomposed and/or seasonally adjusted time series.

OUTSEASON= *SAS-data-set*

names the output data set to contain the seasonal statistics. The statistics are computed for each season as specified by the ID statement INTERVAL= option or the PROC TIMESERIES statement SEASONALITY= option. The OUTSEASON= data set is particularly useful when analyzing transactional data for seasonal variations.

OUTSPECTRA= *SAS-data-set*

names the output data set to contain the univariate frequency domain analysis results.

OUTSSA= *SAS-data-set*

names the output data set to contain the singular spectrum analysis result series.

OUTSUM= *SAS-data-set*

names the output data set to contain the descriptive statistics. The descriptive statistics are based on the accumulated time series when the ACCUMULATE= and/or SETMISSING= options are specified in the ID or VAR statements. The OUTSUM= data set is particularly useful when analyzing large numbers of series and a summary of the results are needed.

OUTTREND= *SAS-data-set*

names the output data set to contain the trend statistics. The statistics are computed for each time period as specified by the ID statement INTERVAL= option. The OUTTREND= data set is particularly useful when analyzing transactional data for trends.

PLOTS= *option* | (*options*)

specifies the univariate graphical output desired. By default, the TIMESERIES procedure produces no graphical output. The following plotting options are available:

SERIES	plots the time series (OUT= data set).
RESIDUAL	plots the residual time series (OUT= data set).

CYCLES	plots the seasonal cycles (OUT= data set).
CORR	plots the correlation panel (OUTCORR= data set).
ACF	plots the autocorrelation function (OUTCORR= data set).
PACF	plots the partial autocorrelation function (OUTCORR= data set).
IACF	plots the inverse autocorrelation function (OUTCORR= data set).
WN	plots the white noise probabilities (OUTCORR= data set).
DECOMP	plots the seasonal adjustment panel (OUTDECOMP= data set).
TCS	plots the trend-cycle-seasonal component (OUTDECOMP= data set).
TCC	plots the trend-cycle component (OUTDECOMP= data set).
SIC	plots the seasonal-irregular component (OUTDECOMP= data set).
SC	plots the seasonal component (OUTDECOMP= data set).
SA	plots the seasonal adjusted component (OUTDECOMP= data set).
PCSA	plots the percent change in the seasonal adjusted component (OUTDECOMP= data set).
IC	plots the irregular component (OUTDECOMP= data set).
TC	plots the trend component (OUTDECOMP= data set).
CC	plots the cycle component (OUTDECOMP= data set).
PERIODOGRAM	plots the periodogram (OUTSPECTRA= data set).
SPECTRUM	plots the spectral density estimate (OUTSPECTRA= data set).
SSA	plots the singular spectrum analysis results (OUTSSA= data set).
ALL	same as PLOTS=(SERIES ACF PACF IACF WN SSA).

For example, PLOTS=SERIES plots the time series. The PLOTS= option produces graphical output for these results by using the Output Delivery System (ODS). The PLOTS= option produces results similar to the data sets listed in parentheses next to the preceding options.

PRINT= *option* | (*options*)

specifies the printed output desired. By default, the TIMESERIES procedure produces no printed output. The following printing options are available:

DECOMP	prints the seasonal decomposition/adjustment table (OUTDECOMP= data set).
SEASONS	prints the seasonal statistics table (OUTSEASON= data set).
DESCSTATS	prints the descriptive statistics for the accumulated time series (OUTSUM= data set).
SUMMARY	prints the descriptive statistics table for all time series (OUTSUM= data set).
TRENDS	prints the trend statistics table (OUTTREND= data set).

SSA prints the singular spectrum analysis results (OUTSSA= data set).
 ALL same as PRINT=(DESCSTATS SUMMARY).

For example, PRINT=SEASONS prints the seasonal statistics. The PRINT= option produces printed output for these results by using the Output Delivery System (ODS). The PRINT= option produces results similar to the data sets listed in parentheses next to the preceding options.

PRINTDETAILS

specifies that output requested with the PRINT= option be printed in greater detail.

SEASONALITY= *number*

specifies the length of the seasonal cycle. For example, SEASONALITY=3 means that every group of three time periods forms a seasonal cycle. By default, the length of the seasonal cycle is one (no seasonality) or the length implied by the INTERVAL= option specified in the ID statement. For example, INTERVAL=MONTH implies that the length of the seasonal cycle is 12.

SORTNAMES

specifies that the variables specified in the VAR and CROSSVAR statements be processed in sorted order by the variable names. This option allows the output data sets to be presorted by the variable names.

BY Statement

A BY statement can be used with PROC TIMESERIES to obtain separate dummy variable definitions for groups of observations defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the option NOTSORTED or DESCENDING in the BY statement for the TIMESERIES procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

CORR Statement

CORR *statistics* < / *options* > ;

A CORR statement can be used with the TIMESERIES procedure to specify options related to time domain analysis of the accumulated time series. Only one CORR statement is allowed.

The following time domain statistics are available:

LAG	time lag
N	number of variance products
ACOV	autocovariances
ACF	autocorrelations
ACFSTD	autocorrelation standard errors
ACF2STD	an indicator of whether autocorrelations are less than (-1), greater than (1), or within (0) two standard errors of zero
ACFNORM	normalized autocorrelations
ACFPROB	autocorrelation probabilities
ACFLPROB	autocorrelation log probabilities
PACF	partial autocorrelations
PACFSTD	partial autocorrelation standard errors
PACF2STD	an indicator of whether partial autocorrelation are less than (-1), greater than (1), or within (0) two standard errors of zero
PACFNORM	partial normalized autocorrelations
PACFPROB	partial autocorrelation probabilities
PACFLPROB	partial autocorrelation log probabilities
IACF	inverse autocorrelations
IACFSTD	inverse autocorrelation standard errors
IACF2STD	an indicator of whether the inverse autocorrelation is less than (-1), greater than (1) or within (0) two standard errors of zero
IACFNORM	normalized inverse autocorrelations
IACFPROB	inverse autocorrelation probabilities
IACFLPROB	inverse autocorrelation log probabilities
WN	white noise test statistics
WNPROB	white noise test probabilities
WNLPROB	white noise test log probabilities

If none of the correlation statistics are specified, the default is as follows:

```
corr lag n acov acf acfstd pacf pacfstd iacf iacfstd wn wnprob;
```

The following options can be specified in the CORR statement following the slash (/):

NLAG= *number*

specifies the number of lags to be stored in the OUTCORR= data set or to be plotted. The default is 24 or three times the length of the seasonal cycle, whichever is smaller. The LAGS= option takes precedence over the NLAG= option.

LAGS= (*numlist*)

specifies the list of lags to be stored in OUTCORR= data set or to be plotted. The list of lags must be separated by spaces or commas. For example, LAGS=(1,3) specifies the first then third lag.

NPARMS= *number*

specifies the number of parameters used in the model that created the residual time series. The number of parameters determines the degrees of freedom associated with the Ljung-Box statistics. The default is NPARMS=0. This option is useful when analyzing the residuals of a time series model with the number of parameters specified by NPARMS=*number* option.

TRANSPOSE= NO|YES

specifies which values are recorded as column names in the OUTCORR= data set. TRANSPOSE=YES specifies that lags be recorded as the column names instead of correlation statistics as the column names. The TRANSPOSE=NO option is useful for graphing the correlation results with SAS/GRAPH procedures. The TRANSPOSE=YES option is useful for analyzing the correlation results with other SAS procedures such as the CLUSTER procedure of SAS/STAT or SAS Enterprise Miner software. The default is TRANSPOSE=NO.

CROSSCORR Statement

```
CROSSCORR statistics < / options > ;
```

A CROSSCORR statement can be used with the TIMESERIES procedure to specify options that are related to cross-correlation analysis of the accumulated time series. Only one CROSSCORR statement is allowed.

The following time domain statistics are available:

LAG	time lag
N	number of variance products
CCOV	cross covariances
CCF	cross-correlations
CCFSTD	cross-correlation standard errors
CCF2STD	an indicator of whether cross-correlations are less than (−1), greater than (1), or within (0) two standard errors of zero

CCFNORM	normalized cross-correlations
CCFPROB	cross-correlation probabilities
CCFLPROB	cross-correlation log probabilities

If none of the cross-correlation statistics are specified, the default is as follows:

```
crosscorr lag n ccov ccf ccfstd;
```

The following options can be specified in the CROSSCORR statement following the slash (/):

NLAG= *number*

specifies the number of lags to be stored in the OUTCROSSCORR= data set or to be plotted. The default is 24 or three times the length of the seasonal cycle, whichever is smaller. The LAGS= option takes precedence over the NLAG= option.

LAGS=(*numlist* **)**

specifies a list of lags to be stored in OUTCROSSCORR= data set or to be plotted. The list of lags must be separated by spaces or commas. For example, LAGS=(1,3) specifies the first then third lag.

TRANSPPOSE= NO|YES

specifies which values are recorded as column names in the OUTCROSSCORR= data set. TRANSPPOSE=YES specifies that the lags be recorded as the column names instead of the cross-correlation statistics. The TRANSPPOSE=NO option is useful for graphing the cross-correlation results with SAS/GRAPH procedures. The TRANSPPOSE=YES option is useful for analyzing the cross-correlation results with other procedures such as the CLUSTER procedure of SAS/STAT or SAS Enterprise Miner software. The default is TRANSPPOSE=NO.

DECOMP Statement

```
DECOMP components < / options > ;
```

A DECOMP statement can be used with the TIMESERIES procedure to specify options related to classical seasonal decomposition of the time series data. Only one DECOMP statement is allowed. The options specified affect all variables listed in the VAR statements. Decomposition can be performed only when the length of the seasonal cycle specified by the PROC TIMESERIES statement SEASONALITY= option or implied by the ID statement INTERVAL= option is greater than one.

The following seasonal decomposition components are available:

ORIG ORIGINAL	original series
TCC TRENDCYCLE	trend-cycle component
SIC SEASONIRREGULAR	seasonal-irregular component

SC SEASONAL	seasonal component
SCSTD	seasonal component standard errors
TCS TRENDCYCLESEASON	trend-cycle-seasonal component
IC IRREGULAR	irregular component
SA ADJUSTED	seasonally adjusted series
PCSA	percent change seasonally adjusted series
TC	trend component
CC CYCLE	cycle component

If none of the components are specified, the default is as follows:

```
decomp orig tcc sc ic sa;
```

The following options can be specified in the DECOMP statement following the slash (/):

MODE= *option*

specifies the type of decomposition to be used to decompose the time series. The following values can be specified for the MODE= option:

ADD ADDITIVE	additive decomposition
MULT MULTIPLICATIVE	multiplicative decomposition
LOGADD LOGADDITIVE	log-additive decomposition
PSEUDOADD PSEUDOADDITIVE	pseudo-additive decomposition
MULTORADD	multiplicative or additive decomposition, depending on data

Multiplicative and log additive decomposition require strictly positive time series. If the accumulated time series contains nonpositive values and the MODE=MULT or MODE=LOGADD option is specified, an error results. Pseudo-additive decomposition requires a nonnegative-valued time series. If the accumulated time series contains negative values and the MODE=PSEUDOADD option is specified, an error results. The MODE=MULTORADD option specifies that multiplicative decomposition be used when the accumulated time series contains only positive values, that pseudo-additive decomposition be used when the accumulated time series contains only nonnegative values, and that additive decomposition be used otherwise. The default is MODE=MULTORADD.

LAMBDA= *number*

specifies the Hodrick-Prescott filter parameter for trend-cycle decomposition. The default is LAMBDA=1600. Filtering applies when the trend component or the cycle component is requested. If filtering is not specified, this option is ignored.

NPERIODS= *number*

specifies the number of time periods to be stored in the OUTDECOMP= data set when the TRANSPOSE=YES option is specified. If the TRANSPOSE=NO option is specified, the

NPERIODS= option is ignored. If the NPERIODS= option is positive, the first or beginning time periods are recorded. If the NPERIODS= option is negative, the last or ending time periods are recorded. The NPERIODS= option specifies the number of OUTDECOMP= data set variables to contain the seasonal decomposition and is therefore limited to the maximum allowed number of SAS variables. If the number of time periods exceeds this limit, a warning is printed in the log and the number of periods stored is reduced to the limit.

If the NPERIODS= option is not specified, all of the periods specified between the ID statement START= and END= options are stored. If at least one of the START= or END= options is not specified, the default magnitude is the seasonality specified by the SEASONALITY= option in the PROC TIMESERIES statement or implied by the INTERVAL= option in the ID statement. If only the START= option or both the START= and END= options are specified and the seasonality is zero, the default is NPERIODS=5. If only the END= option or neither the START= nor END= option is specified and the seasonality is zero, the default is NPERIODS=-5.

TRANSPOSE= NO | YES

specifies which values are recorded as column names in the OUTDECOMP= data set. TRANSPOSE=YES specifies that the time periods be recorded as the column names instead of the statistics. The first and last time periods stored in the OUTDECOMP= data set correspond to the period of the ID statement START= option and END= option, respectively. If only the ID statement END= option is specified, the last time ID value of each accumulated time series corresponds to the last time period column. If only the ID statement START= option is specified, the first time ID value of each accumulated time series corresponds to the first time period column. If neither the START= option nor the END= option is specified with the ID statement, the first time ID value of each accumulated time series corresponds to the first time period column. The TRANSPOSE=NO option is useful for analyzing or displaying the decomposition results with SAS/GRAPH procedures. The TRANSPOSE=YES option is useful for analyzing the decomposition results with other SAS procedures or SAS Enterprise Miner software. The default is TRANSPOSE=NO.

ID Statement

ID *variable* INTERVAL=*interval* < *options* > ;

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date or datetime values. In addition, the ID statement specifies the (desired) frequency associated with the time series. The ID statement *options* also specify how the observations are accumulated and how the time ID values are aligned to form the time series. The information specified affects all variables listed in subsequent VAR statements. If the ID statement is specified, the INTERVAL= must also be used. If an ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID.

The following *options* can be used with the ID statement:

ACCUMULATE= *option*

specifies how the data set observations are to be accumulated within each time period. The

frequency (width of each time interval) is specified by the INTERVAL= option. The ID variable contains the time ID values. Each time ID variable value corresponds to a specific time period. The accumulated values form the time series, which is used in subsequent analysis.

The ACCUMULATE= option is useful when there are zero or more than one input observations that coincide with a particular time period (for example, time-stamped transactional data). The EXPAND procedure offers additional frequency conversions and transformations that can also be useful in creating a time series.

The following *options* determine how the observations are accumulated within each time period based on the ID variable and the frequency specified by the INTERVAL= option:

NONE	No accumulation occurs; the ID variable values must be equally spaced with respect to the frequency. This is the default option.
TOTAL	Observations are accumulated based on the total sum of their values.
AVERAGE AVG	Observations are accumulated based on the average of their values.
MINIMUM MIN	Observations are accumulated based on the minimum of their values.
MEDIAN MED	Observations are accumulated based on the median of their values.
MAXIMUM MAX	Observations are accumulated based on the maximum of their values.
N	Observations are accumulated based on the number of nonmissing observations.
NMISS	Observations are accumulated based on the number of missing observations.
NOBS	Observations are accumulated based on the number of observations.
FIRST	Observations are accumulated based on the first of their values.
LAST	Observations are accumulated based on the last of their values.
STDDEV STD	Observations are accumulated based on the standard deviation of their values.
CSS	Observations are accumulated based on the corrected sum of squares of their values.
USS	Observations are accumulated based on the uncorrected sum of squares of their values.

If the ACCUMULATE= option is specified, the SETMISSING= option is useful for specifying how accumulated missing values are to be treated. If missing values should be interpreted as zero, then SETMISSING=0 should be used. The section “[Details: TIMESERIES Procedure](#)” on page 1876 describes accumulation in greater detail.

ALIGN= *option*

controls the alignment of SAS dates used to identify output observations. The ALIGN= option accepts the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. BEGINNING is the default.

BOUNDARYALIGN= *option*

controls how the ACCUMULATE= option is processed for the two boundary time intervals, which include the START= and END= time ID values. Some time ID values might fall inside the first and last accumulation intervals but fall outside the START= and END= boundaries. In these cases the BOUNDARYALIGN= option determines which values to include in the accumulation operation. You can specify the following *options*:

NONE	No values outside the START= and END= boundaries are accumulated.
START	All observations in the first time interval are accumulated.
END	All observations in the last time interval are accumulated.
BOTH	All observations in the first and last are accumulated.

If no option is specified, the default value BOUNDARYALIGN=NONE is used. The section “[Details: TIMESERIES Procedure](#)” on page 1876 describes the BOUNDARYALIGN= accumulation option in greater detail.

END= *option*

specifies a SAS date or datetime value that represents the end of the data. If the last time ID variable value is less than the END= value, the series is extended with missing values. If the last time ID variable value is greater than the END= value, the series is truncated. For example, END=“&sysdate”D uses the automatic macro variable SYSDATE to extend or truncate the series to the current date. The START= and END= options can be used to ensure that data associated within each BY group contains the same number of observations.

FORMAT= *format*

specifies the SAS format for the time ID values. If the FORMAT= option is not specified, the default format is implied from the INTERVAL= option.

INTERVAL= *interval*

specifies the frequency of the accumulated time series. For example, if the input data set consists of quarterly observations, then INTERVAL=QTR should be used. If the PROC TIMESERIES statement SEASONALITY= option is not specified, the length of the seasonal cycle is implied from the INTERVAL= option. For example, INTERVAL=QTR implies a seasonal cycle of length 4. If the ACCUMULATE= option is also specified, the INTERVAL= option determines the time periods for the accumulation of observations. The INTERVAL= option is required and must be the first option specified in the ID statement.

NOTSORTED

specifies that the time ID values not be in sorted order. The TIMESERIES procedure sorts the data with respect to the time ID prior to analysis.

SETMISSING= *option* | *number*

specifies how missing values (either actual or accumulated) are to be interpreted in the accumulated time series. If a number is specified, missing values are set to the number. If a missing value indicates an unknown value, this option should not be used. If a missing value indicates no value, SETMISSING=0 should be used. You would typically use SETMISSING=0 for transactional data because no recorded data usually implies no activity. The following options can also be used to determine how missing values are assigned:

MISSING	Missing values are set to missing. This is the default option.
AVERAGE AVG	Missing values are set to the accumulated average value.
MINIMUM MIN	Missing values are set to the accumulated minimum value.
MEDIAN MED	Missing values are set to the accumulated median value.
MAXIMUM MAX	Missing values are set to the accumulated maximum value.
FIRST	Missing values are set to the accumulated first nonmissing value.
LAST	Missing values are set to the accumulated last nonmissing value.
PREVIOUS PREV	Missing values are set to the previous period's accumulated nonmissing value. Missing values at the beginning of the accumulated series remain missing.
NEXT	Missing values are set to the next period's accumulated nonmissing value. Missing values at the end of the accumulated series remain missing.

START= *option*

specifies a SAS date or datetime value that represents the beginning of the data. If the first time ID variable value is greater than the START= value, the series is prepended with missing values. If the first time ID variable value is less than the START= value, the series is truncated. The START= and END= options can be used to ensure that data associated with each by group contains the same number of observations.

SEASON Statement

SEASON *statistics* < / *options* > ;

A SEASON statement can be used with the TIMESERIES procedure to specify options that are related to seasonal analysis of the time-stamped transactional data. Only one SEASON statement is allowed. The options specified affect all variables specified in the VAR statements. Seasonal analysis can be performed only when the length of the seasonal cycle specified by the PROC TIMESERIES statement SEASONALITY= option or implied by the ID statement INTERVAL= option is greater than one.

The following seasonal statistics are available:

NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
RANGE	range value
SUM	summation value

MEAN	mean value
STDDEV	standard deviation
CSS	corrected sum of squares
USS	uncorrected sum of squares
MEDIAN	median value

If none of the season statistics are specified, the default is as follows:

```
season n min max mean std;
```

The following option can be specified in the SEASON statement following the slash (/):

TRANSPOSE= NO | YES

specifies which values are recorded as column names in the OUTSEASON= data set. TRANSPOSE=YES specifies that the seasonal indices be recorded as the column names instead of the statistics. The TRANSPOSE=NO option is useful for graphing the seasonal analysis results with SAS/GRAPH procedures. The TRANSPOSE=YES option is useful for analyzing the seasonal analysis results with SAS procedures or SAS Enterprise Miner software. The default is TRANSPOSE=NO.

SPECTRA Statement

```
SPECTRA statistics < / options > ;
```

A SPECTRA statement can be used with the TIMESERIES procedure to specify which statistics appear in the OUTSPECTRA= data set. The SPECTRA statement *options* are used in performing a spectral analysis on the variables listed in the VAR statement. These *options* affect values that are produced in the PROC TIMESERIES statement's OUTSPECTRA= data set, and in the periodogram and spectral density estimate. Only one SPECTRA statement is allowed.

The following univariate frequency domain statistics are available:

FREQ	frequency in radians from 0 to π
PERIOD	period or wavelength
COS	cosine transform
SIN	sine transform
P	periodogram
S	spectral density estimates

If none of the frequency domain statistics are specified, the default is as follows:

```
spectra period p;
```

The following *options* can be specified in the SPECTRA statement following the slash (/):

ADJMEAN | CENTER

subtracts the series mean before performing the Fourier decomposition. This sets the first periodogram ordinate to 0 rather than to $2n$ times the squared mean. This option is commonly used when the periodograms are to be plotted to prevent a large first periodogram ordinate from distorting the scale of the plot.

ALPHA= num

specifies the width of a window drawn around the spectral density estimate in a spectral density versus frequency plot. Based on approximations proposed by Brockwell and Davis (1991), periodogram ordinates fall within this window with a confidence level of $1 - \text{ALPHA}$. The value ALPHA must be between 0 and 1; the default is 0.5.

kernel **DOMAIN=domain C=c EXP|EXPON=e**

specifies the smoothing function used to calculate a spectral density estimate as the moving average of periodogram ordinates. The kernel function is an alternative way to using the WEIGHTS option as a smoothing function. The available *kernel* values are:

PARZEN	Parzen kernel
BART BARTLETT	Bartlett kernel
TUK TUKEY	Tukey-Hanning kernel
TRUNC TRUNCAT	truncated kernel
QS QUADR	quadratic spectral kernel

The DOMAIN= option specifies how the smoothing function is interpreted. The available *domain* values are:

FREQUENCY	smooths the periodogram ordinates.
TIME	applies the kernel as a filter to the time series. autocovariance function

By default DOMAIN=FREQUENCY, and smoothing is applied in the same manner as weights are applied when the WEIGHTS= option is used. Each of the kernel functions can be further parameterized by a bandwidth value by using the C= and EXPON= options. A summary of the default values of the bandwidth parameters, c and e , that are associated with the kernel functions and the bandwidth values, M , for a series with 100 periodogram ordinates is listed in [Table 29.2](#).

Table 29.2 Default Bandwidth Parameters

Kernel	c	e	M
Bartlett	1/2	1/3	2.32
Parzen	1	1/5	2.51
Quadratic	1/2	1/5	1.26
Tukey-Hanning	2/3	1/5	1.67
Truncated	1/4	1/5	0.63

For example, to apply the truncated kernel by using default bandwidth parameters in the frequency domain, the following SPECTRA statement could be used:

```
spectra / truncat;
```

Details of the kernel function bandwidth parameterization and the DOMAIN= option are provided in the section “Using Kernel Specifications” on page 1886.

WEIGHTS *numlist*

specifies the relative weights used in computing a spectral density estimate as the moving average smoothing of periodogram ordinates. If neither a WEIGHTS option nor a kernel function is specified, the spectral density estimate is identical to the unmodified periodogram. The following SPECTRA statement uses the WEIGHTS option to specify equal weighting for each of the three adjacent periodogram ordinates centered on each spectral density estimate:

```
spectra / weights 1 1 1;
```

Further description of how the weights are applied is provided in the section “Using Specification of Weight Constants” on page 1886.

SSA Statement

```
SSA < / options > ;
```

An SSA statement can be used with the TIMESERIES procedure to specify *options* that are related to singular spectrum analysis (SSA) of the accumulated time series. Only one SSA statement is allowed.

The following *options* can be specified in the SSA statement following the slash (/).

GROUPS= (*numlist*)...(*numlist*)

specifies the lists that categorize window lags into groups. The window lags must be separated by spaces or commas. For example, GROUPS=(1,3) (2,4) specifies that the first and third window lags form the first group and the second and fourth window lags form the second group. If no GROUPS= option is specified, the window lags are divided into two groups based on the THRESHOLDPCT= value.

For example, the following SSA statement specifies three groups:

```
ssa / groups=(1 3) (2 4 5) (6);
```

The first group contains the first and third principal components; the second group contains the second, fourth, and fifth principal components; and the third group contains the sixth principal component.

By default, the first group contains the principal components whose contribution to variability in the series sums to greater than the THRESHOLDPCT= value of 90%, and the second group contains the remaining components.

LENGTH = number

specifies the window length to be used in the analysis. It represents the maximum lag used in the SSA autocovariance calculations. The number specified by the LENGTH= option must be greater than one and less than 1000. When the SEASONALITY= option is provided or inferred by the INTERVAL= option in the ID statement the default window length is the smaller of two times the length of the seasonal cycle and one half the length of the time series. When no seasonality value is available the default window length is the smaller of 12 and one half the length of the time series.

For example, the following SSA statement specifies a window length of 10:

```
ssa / length=10;
```

If no window length option is specified and the INTERVAL=MONTH or SEASONALITY=12 options are specified, a window length of 24 is used. If the specified window length is greater than one-half the length of the accumulated time series, the window length is reduced and a warning message is printed to the log.

NPERIODS= number

specifies the number of time periods to be stored in the OUTSSA= data set when the TRANSPOSE=YES option is specified. If the TRANSPOSE option is not specified, the NPERIODS= option is ignored. The NPERIODS= option specifies the number of OUTSSA= data set variables to contain the groups.

If the NPERIODS= option is not specified, all of the periods specified between the ID statement START= and END= options are stored. If at least one of the START= or END= options is not specified, the default magnitude is the seasonality specified by the SEASONALITY= option in the PROC TIMESERIES statement or implied by the INTERVAL= option in the ID statement. If only the START= option or both the START= and END= options are specified and the seasonality is zero, the default is NPERIODS=5. If only the END= option or neither the START= nor END= option is specified and the seasonality is zero, the default is NPERIODS=-5.

THRESHOLDPCT= percent

specifies a percentage used to divide the SSA components into two groups based on the cumulative percentage of their singular values. The percentage specified by the THRESHOLDPCT= option must be greater than zero and less than 100. The default is THRESHOLDPCT=90.

For example, the following SSA statement specifies 80%:

```
ssa / THRESHOLDPCT=80;
```

The size of the second group must be at least one, and it must be less than the window length. The percentage is adjusted to achieve this requirement.

For example, the following SSA statement specifies a THRESHOLDPCT= of 0%, which effectively sets the size of the second group to one less than the window length:

```
ssa / THRESHOLDPCT = 0;
```

The following SSA statement specifies a THRESHOLDPCT= of 100%, which implies that the size of the last group is one:

```
ssa / THRESHOLDPCT= 100;
```

TRANSPOSE= NO | YES

specifies which values are recorded as column names in the OUTSSA= data set. TRANSPOSE=YES specifies that the time periods be recorded as the column names instead of the specified groups as the column names. The first and last time period stored in the OUTSSA= data set corresponds to the period of the ID statement START= and END= options, respectively. If only the ID statement END= option is specified, the last time ID value of each accumulated time series corresponds to the last time period column. If only the ID statement START= option is specified, the first time ID value of each accumulated time series corresponds to the first time period column. If neither the START= option nor the END= option is specified with the ID statement, the first time ID value of each accumulated time series corresponds to the first time period column. The TRANSPOSE=NO option is useful for displaying the SSA results. The TRANSPOSE=YES option is useful for analyzing the SSA results using SAS Enterprise Miner software. The default is TRANSPOSE=NO.

TREND Statement

```
TREND statistics < / options > ;
```

A TREND statement can be used with the TIMESERIES procedure to specify options related to trend analysis of the time-stamped transactional data. Only one TREND statement is allowed. The options specified affect all variables specified in the VAR statements.

The following trend statistics are available:

NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
RANGE	range value
SUM	summation value
MEAN	mean value

STDDEV	standard deviation
CSS	corrected sum of squares
USS	uncorrected sum of squares
MEDIAN	median value

If none of the trend statistics are specified, the default is as follows:

```
trend n min max mean std;
```

The following options can be specified in the TREND statement following the slash (/):

NPERIODS= *number*

specifies the number of time periods to be stored in the OUTTREND= data set when the TRANSPOSE=YES option is specified. If the TRANSPOSE option is not specified, the NPERIODS= option is ignored. The NPERIODS= option specifies the number of OUTTREND= data set variables to contain the trend statistics and is therefore limited to the maximum allowed number of SAS variables.

If the NPERIODS= option is not specified, all of the periods specified between the ID statement START= and END= options are stored. If at least one of the START= or END= options is not specified, the default magnitude is the seasonality specified by the SEASONALITY= option in the PROC TIMESERIES statement or implied by the INTERVAL= option in the ID statement. If only the START= option or both the START= and END= options are specified and the seasonality is zero, the default is NPERIODS=5. If only the END= option or neither the START= nor END= option is specified and the seasonality is zero, the default is NPERIODS=-5.

TRANSPOSE= NO | YES

specifies which values are recorded as column names in the OUTTREND= data set. TRANSPOSE=YES specifies that the time periods be recorded as the column names instead of the statistics as the column names. The first and last time periods stored in the OUTTREND= data set correspond to the period of the ID statement START= and END= options, respectively. If only the ID statement END= option is specified, the last time ID value of each accumulated time series corresponds to the last time period column. If only the ID statement START= option is specified, the first time ID value of each accumulated time series corresponds to the first time period column. If neither the START= option nor the END= option is specified with the ID statement, the first time ID value of each accumulated time series corresponds to the first time period column. The TRANSPOSE=NO option is useful for analyzing or displaying the trend analysis results with SAS/GRAPH procedures. The TRANSPOSE=YES option is useful for analyzing the trend analysis results with other SAS procedures or SAS Enterprise Miner software. The default is TRANSPOSE=NO.

VAR and CROSSVAR Statements

```
VAR variable-list < / options > ;
```

CROSSVAR *variable-list* < / *options* > ;

The VAR and CROSSVAR statements list the numeric variables in the DATA= data set whose values are to be accumulated to form the time series.

An input data set variable can be specified in only one VAR or CROSSVAR statement. Any number of VAR and CROSSVAR statements can be used. The following options can be used with the VAR and CROSSVAR statements:

ACCUMULATE= *option*

specifies how the data set observations are to be accumulated within each time period for the variables listed in the VAR or CROSSVAR statement. If the ACCUMULATE= option is not specified in the VAR or CROSSVAR statement, accumulation is determined by the ACCUMULATE= option of the ID statement. See the ID statement ACCUMULATE= option for more details.

DIF=(*numlist*)

specifies the differencing to be applied to the accumulated time series. The list of differencing orders must be separated by spaces or commas. For example, DIF=(1,3) specifies first then third order differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the DIF= option.

SDIF=(*numlist*)

specifies the seasonal differencing to be applied to the accumulated time series. The list of seasonal differencing orders must be separated by spaces or commas. For example, SDIF=(1,3) specifies first then third order seasonal differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the SDIF= option.

SETMISS= *option* | *number*

SETMISSING= *option* | *number*

specifies how missing values (either actual or accumulated) are to be interpreted in the accumulated time series for variables listed in the VAR or CROSSVAR statement. If the SETMISSING= option is not specified in the VAR or CROSSVAR statement, missing values are set based on the SETMISSING= option of the ID statement. See the ID statement SETMISSING= option for more details.

TRANSFORM= *option*

specifies the time series transformation to be applied to the accumulated time series. The following transformations are provided:

NONE	No transformation is applied. This option is the default.
LOG	logarithmic transformation
SQRT	square-root transformation
LOGISTIC	logistic transformation
BOXCOX(<i>n</i>)	Box-Cox transformation with parameter number where the number is between -5 and 5

When the TRANSFORM= option is specified, the time series must be strictly positive.

Details: TIMESERIES Procedure

The TIMESERIES procedure can be used to perform trend and seasonal analysis on transactional data. For trend analysis, various sample statistics are computed for each time period defined by the time ID variable and INTERVAL= option. For seasonal analysis, various sample statistics are computed for each season defined by the INTERVAL= or the SEASONALITY= option. For example, if the transactional data ranges from June 1990 to January 2000 and the data are to be accumulated on a monthly basis, then the trend statistics are computed for every month: June 1990, July 1990, . . . , January 2000. The seasonal statistics are computed for each season: January, February, . . . , December.

The TIMESERIES procedure can be used to form time series data from transactional data. The accumulated time series can then be analyzed using time series techniques. The data is analyzed in the following order:

- | | |
|---------------------------------|--|
| 1. accumulation | ACCUMULATE= option in the ID, VAR, or CROSSVAR statement |
| 2. missing value interpretation | SETMISSING= option in the ID, VAR, or CROSSVAR statement |
| 3. time series transformation | TRANSFORM= option in the VAR or CROSSVAR statement |
| 4. time series differencing | DIF= and SDIF= options in the VAR or CROSSVAR statement |
| 5. descriptive statistics | OUTSUM= option and the PRINT=DESCSTATS option |
| 6. seasonal decomposition | DECOMP statement or the OUTDECOMP= option in the PROC TIMESERIES statement |
| 7. correlation analysis | CORR statement or the OUTCORR= option in the PROC TIMESERIES statement |
| 8. singular spectrum analysis | SSA statement or the OUTSSA= option in the PROC TIMESERIES statement |
| 9. Fourier spectral analysis | SPECTRA statement or the OUTSPECTRA= option in the PROC TIMESERIES statement |
| 10. cross-correlation analysis | CROSSCORR statement or the OUTCROSSCORR= option in the PROC TIMESERIES statement |

Accumulation

If the ACCUMULATE= option in the ID, VAR, or CROSSVAR statement is specified, data set observations are accumulated within each time period. The frequency (width of each time interval)

is specified by the ID statement INTERVAL= option. The ID variable contains the time ID values. Each time ID value corresponds to a specific time period. Accumulation is useful when the input data set contains transactional data, whose observations are not spaced with respect to any particular time interval. The accumulated values form the time series, which is used in subsequent analyses.

For example, suppose a data set contains the following observations:

```

19MAR1999    10
19MAR1999    30
11MAY1999    50
12MAY1999    20
23MAY1999    20

```

If the INTERVAL=MONTH is specified, all of the above observations fall within a three-month period of time between March 1999 and May 1999. The observations are accumulated within each time period as follows:

If the ACCUMULATE=NONE option is specified, an error is generated because the ID variable values are not equally spaced with respect to the specified frequency (MONTH).

If the ACCUMULATE=TOTAL option is specified, the resulting time series is:

```

01MAR1999    40
01APR1999    .
01MAY1999    90

```

If the ACCUMULATE=AVERAGE option is specified, the resulting time series is:

```

01MAR1999    20
01APR1999    .
01MAY1999    30

```

If the ACCUMULATE=MINIMUM option is specified, the resulting time series is:

```

01MAR1999    10
01APR1999    .
01MAY1999    20

```

If the ACCUMULATE=MEDIAN option is specified, the resulting time series is:

```

01MAR1999    20
01APR1999    .
01MAY1999    20

```

If the ACCUMULATE=MAXIMUM option is specified, the resulting time series is:

```

O1MAR1999    30
O1APR1999    .
O1MAY1999    50

```

If the ACCUMULATE=FIRST option is specified, the resulting time series is:

```

O1MAR1999    10
O1APR1999    .
O1MAY1999    50

```

If the ACCUMULATE=LAST option is specified, the resulting time series is:

```

O1MAR1999    30
O1APR1999    .
O1MAY1999    20

```

If the ACCUMULATE=STDDEV option is specified, the resulting time series is:

```

O1MAR1999    14.14
O1APR1999    .
O1MAY1999    17.32

```

As can be seen from the above examples, even though the data set observations contain no missing values, the accumulated time series can have missing values.

Boundary Alignment

When the BOUNDARYALIGN= option is used to qualify the START= or END= options, additional time series values can be incorporated into the accumulation operation. For instance, if a data set contains the following observations

```

O1JAN1999    10
O1FEB1999    10
O1MAR1999    10
O1APR1999    10
O1MAY1999    10
O1JUN1999    10

```

and the options START='01FEB1999'd, END='01APR1999'd, INTERVAL=QUARTER, and ACCUMULATE=TOTAL are specified, using the BOUNDARYALIGN= option results in the following accumulated time series:

If BOUNDARYALIGN=START is specified, the accumulated time series is

```

O1JAN1999    30
O1APR1999    10

```

If BOUNDARYALIGN=END is specified, the accumulated time series is

```
01JAN1999 20
01APR1999 30
```

If BOUNDARYALIGN=BOTH is specified, the accumulated time series is

```
01JAN1999 30
01APR1999 30
```

If BOUNDARYALIGN=NONE is specified, the accumulated time series is

```
01JAN1999 20
01APR1999 10
```

Missing Value Interpretation

Sometimes missing values should be interpreted as unknown values. But sometimes missing values are known, such as when missing values are created from accumulation and no observations should be interpreted as no value—that is, zero. In the former case, the SETMISSING= option can be used to interpret how missing values are treated. The SETMISSING=0 option should be used when missing observations are to be treated as no (zero) values. In other cases, missing values should be interpreted as global values, such as minimum or maximum values of the accumulated series. The accumulated and interpreted time series is used in subsequent analyses.

Time Series Transformation

There are four transformations available for strictly positive series only. Let $y_t > 0$ be the original time series, and let w_t be the transformed series. The transformations are defined as follows:

Log is the logarithmic transformation.

$$w_t = \ln(y_t)$$

Logistic is the logistic transformation.

$$w_t = \ln(cy_t/(1 - cy_t))$$

where the scaling factor c is

$$c = (1 - 10^{-6})10^{-\text{ceil}(\log_{10}(\max(y_t)))}$$

and $\text{ceil}(x)$ is the smallest integer greater than or equal to x .

Square root is the square root transformation.

$$w_t = \sqrt{y_t}$$

Box Cox is the Box-Cox transformation.

$$w_t = \begin{cases} \frac{y_t^\lambda - 1}{\lambda}, & \lambda \neq 0 \\ \ln(y_t), & \lambda = 0 \end{cases}$$

More complex time series transformations can be performed by using the EXPAND procedure of SAS/ETS.

Time Series Differencing

After optionally transforming the series, the accumulated series can be simply or seasonally differenced by using the VAR and CROSSVAR statement DIF= and SDIF= options. For example, suppose y_t is a monthly time series. The following examples of the DIF= and SDIF= options demonstrate how to simply and seasonally difference the time series.

```
dif=(1) sdif=(1)
dif=(1,12)
```

Additionally, when y_t is strictly positive and the TRANSFORM=, DIF=, and SDIF= options are combined in the VAR and CROSSVAR statements, the transformation operation is performed before the differencing operations.

Descriptive Statistics

Descriptive statistics can be computed from the working series by specifying the OUTSUM= option or PRINT=DESCSTATS.

Seasonal Decomposition

Seasonal decomposition/analysis can be performed on the working series by specifying the `OUT-DECOMP=` option, the `PRINT=DECOMP` option, or one of the `PLOTS=` options associated with decomposition in the `PROC TIMESERIES` statement. The `DECOMP` statement enables you to specify options related to decomposition. The `TIMESERIES` procedure uses classical decomposition. More complex seasonal decomposition/adjustment analysis can be performed by using the `X11` or the `X12` procedure of SAS/ETS.

The `DECOMP` statement `MODE=` option determines the mode of the seasonal adjustment decomposition to be performed. There are four modes: multiplicative (`MODE=MULT`), additive (`MODE=ADD`), pseudo-additive (`MODE=PSEUDOADD`), and log-additive (`MODE=LOGADD`) decomposition. The default is `MODE=MULTORADD` which specifies `MODE=MULT` for series that are strictly positive, `MODE=PSEUDOADD` for series that are nonnegative, and `MODE=ADD` for series that are not nonnegative.

When `MODE=LOGADD` is specified, the components are exponentiated to the original metric.

The `DECOMP` statement `LAMBDA=` option specifies the Hodrick-Prescott filter parameter (Hodrick and Prescott 1980). The default is `LAMBDA=1600`. The Hodrick-Prescott filter is used to decompose the trend-cycle component into the trend component and cycle component in an additive fashion. A smaller parameter assigns less significance to the cycle; that is, `LAMBDA=0` implies no cycle component.

The notation and keywords associated with seasonal decomposition/adjustment analysis are defined in [Table 29.3](#).

Table 29.3 Seasonal Adjustment Formulas

Component	Keyword	MODE= Option	Formula
original series	ORIGINAL	MULT	$O_t = TC_t S_t I_t$
		ADD	$O_t = TC_t + S_t + I_t$
		LOGADD	$\log(O_t) = TC_t + S_t + I_t$
		PSEUDOADD	$O_t = TC_t(S_t + I_t - 1)$
trend-cycle component	TCC	MULT	centered moving average of O_t
		ADD	centered moving average of O_t
		LOGADD	centered moving average of $\log(O_t)$
		PSEUDOADD	centered moving average of O_t
seasonal-irregular component	SIC	MULT	$SI_t = S_t I_t = O_t / TC_t$
		ADD	$SI_t = S_t + I_t = O_t - TC_t$
		LOGADD	$SI_t = S_t + I_t = \log(O_t) - TC_t$
		PSEUDOADD	$SI_t = S_t + I_t - 1 = O_t / TC_t$
seasonal component	SC	MULT	seasonal Averages of SI_t
		ADD	seasonal Averages of SI_t
		LOGADD	seasonal Averages of SI_t
		PSEUDOADD	seasonal Averages of SI_t
irregular component	IC	MULT	$I_t = SI_t / S_t$
		ADD	$I_t = SI_t - S_t$
		LOGADD	$I_t = SI_t - S_t$
		PSEUDOADD	$I_t = SI_t - S_t + 1$
trend-cycle-seasonal component	TCS	MULT	$TCS_t = TC_t S_t = O_t / I_t$
		ADD	$TCS_t = TC_t + S_t = O_t - I_t$
		LOGADD	$TCS_t = TC_t + S_t = O_t - I_t$
		PSEUDOADD	$TCS_t = TC_t S_t$
trend component	TC	MULT	$T_t = TC_t - C_t$
		ADD	$T_t = TC_t - C_t$
		LOGADD	$T_t = TC_t - C_t$
		PSEUDOADD	$T_t = TC_t - C_t$
cycle component	CC	MULT	$C_t = TC_t - T_t$
		ADD	$C_t = TC_t - T_t$
		LOGADD	$C_t = TC_t - T_t$
		PSEUDOADD	$C_t = TC_t - T_t$
seasonally adjusted series	SA	MULT	$SA_t = O_t / S_t = TC_t I_t$
		ADD	$SA_t = O_t - S_t = TC_t + I_t$
		LOGADD	$SA_t = O_t / \exp(S_t) = \exp(TC_t + I_t)$
		PSEUDOADD	$SA_t = TC_t I_t$

The trend-cycle component is computed from the s -period centered moving average as follows:

$$TC_t = \sum_{k=-\lfloor s/2 \rfloor}^{\lfloor s/2 \rfloor} y_{t+k} / s$$

The seasonal component is obtained by averaging the seasonal-irregular component for each season.

$$S_{k+js} = \sum_{t=k \bmod s} \frac{SI_t}{T/s}$$

where $0 \leq j \leq T/s$ and $1 \leq k \leq s$. The seasonal components are normalized to sum to one (multiplicative) or zero (additive).

Correlation Analysis

Correlation analysis can be performed on the working series by specifying the OUTCORR= option or one of the PLOTS= options that are associated with correlation. The CORR statement enables you to specify options that are related to correlation analysis.

Autocovariance Statistics

LAGS	$h \in \{0, \dots, H\}$
N	N_h is the number of observed products at lag h , ignoring missing values
ACOV	$\hat{\gamma}(h) = \frac{1}{T} \sum_{t=h+1}^T (y_t - \bar{y})(y_{t-h} - \bar{y})$
ACOV	$\hat{\gamma}(h) = \frac{1}{N_h} \sum_{t=h+1}^T (y_t - \bar{y})(y_{t-h} - \bar{y})$ when embedded missing values are present

Autocorrelation Statistics

ACF	$\hat{\rho}(h) = \hat{\gamma}(h)/\hat{\gamma}(0)$
ACFSTD	$Std(\hat{\rho}(h)) = \sqrt{\frac{1}{T} \left(1 + 2 \sum_{j=1}^{h-1} \hat{\rho}(j)^2 \right)}$
ACFNORM	$Norm(\hat{\rho}(h)) = \hat{\rho}(h)/Std(\hat{\rho}(h))$
ACFPROB	$Prob(\hat{\rho}(h)) = 2(1 - \Phi(Norm(\hat{\rho}(h))))$
ACFLPROB	$LogProb(\hat{\rho}(h)) = -\log_{10}(Prob(\hat{\rho}(h)))$
ACF2STD	$Flag(\hat{\rho}(h)) = \begin{cases} 1 & \hat{\rho}(h) > 2Std(\hat{\rho}(h)) \\ 0 & -2Std(\hat{\rho}(h)) < \hat{\rho}(h) < 2Std(\hat{\rho}(h)) \\ -1 & \hat{\rho}(h) < -2Std(\hat{\rho}(h)) \end{cases}$

Partial Autocorrelation Statistics

PACF	$\hat{\phi}(h) = \Gamma_{(0,h-1)}\{\gamma_j\}_{j=1}^h$
PACFSTD	$Std(\hat{\phi}(h)) = 1/\sqrt{N_0}$
PCFNORM	$Norm(\hat{\phi}(h)) = \hat{\phi}(h)/Std(\hat{\phi}(h))$
PACFPROB	$Prob(\hat{\phi}(h)) = 2(1 - \Phi(Norm(\hat{\phi}(h))))$

$$\begin{aligned} \text{PACFLPROB} \quad & \text{LogProb}(\hat{\varphi}(h)) = -\log_{10}(\text{Prob}(\hat{\varphi}(h))) \\ \text{PACF2STD} \quad & \text{Flag}(\hat{\varphi}(h)) = \begin{cases} 1 & \hat{\varphi}(h) > 2\text{Std}(\hat{\varphi}(h)) \\ 0 & -2\text{Std}(\hat{\varphi}(h)) < \hat{\varphi}(h) < 2\text{Std}(\hat{\varphi}(h)) \\ -1 & \hat{\varphi}(h) < -2\text{Std}(\hat{\varphi}(h)) \end{cases} \end{aligned}$$

Inverse Autocorrelation Statistics

$$\begin{aligned} \text{IACF} \quad & \hat{\theta}(h) \\ \text{IACFSTD} \quad & \text{Std}(\hat{\theta}(h)) = 1/\sqrt{N_0} \\ \text{IACFNORM} \quad & \text{Norm}(\hat{\theta}(h)) = \hat{\theta}(h)/\text{Std}(\hat{\theta}(h)) \\ \text{IACFPROB} \quad & \text{Prob}(\hat{\theta}(h)) = 2 \left(1 - \Phi \left(|\text{Norm}(\hat{\theta}(h))| \right) \right) \\ \text{IACFLPROB} \quad & \text{LogProb}(\hat{\theta}(h)) = -\log_{10}(\text{Prob}(\hat{\theta}(h))) \\ \text{IACF2STD} \quad & \text{Flag}(\hat{\theta}(h)) = \begin{cases} 1 & \hat{\theta}(h) > 2\text{Std}(\hat{\theta}(h)) \\ 0 & -2\text{Std}(\hat{\theta}(h)) < \hat{\theta}(h) < 2\text{Std}(\hat{\theta}(h)) \\ -1 & \hat{\theta}(h) < -2\text{Std}(\hat{\theta}(h)) \end{cases} \end{aligned}$$

White Noise Statistics

$$\begin{aligned} \text{WN} \quad & Q(h) = T(T+2) \sum_{j=1}^h \rho(j)^2 / (T-j) \\ \text{WN} \quad & Q(h) = \sum_{j=1}^h N_j \rho(j)^2 \text{ when embedded missing values are present} \\ \text{WNPROB} \quad & \text{Prob}(Q(h)) = \chi_{\max(1, h-p)}(Q(h)) \\ \text{WNLPROB} \quad & \text{LogProb}(Q(h)) = -\log_{10}(\text{Prob}(Q(h))) \end{aligned}$$

Cross-Correlation Analysis

Cross-correlation analysis can be performed on the working series by specifying the OUTCROSS-CORR= option or one of the CROSSPLOTS= options that are associated with cross-correlation. The CROSSCORR statement enables you to specify options that are related to cross-correlation analysis.

Cross-Correlation Statistics

The cross-correlation statistics for the variable x supplied in a VAR statement and variable y supplied in a CROSSVAR statement are:

$$\begin{aligned} \text{LAGS} \quad & h \in \{0, \dots, H\} \\ \text{N} \quad & N_h \text{ is the number of observed products at lag } h, \text{ ignoring missing values} \\ \text{CCOV} \quad & \hat{\gamma}_{x,y}(h) = \frac{1}{T} \sum_{t=h+1}^T (x_t - \bar{x})(y_{t-h} - \bar{y}) \end{aligned}$$

CCOV	$\hat{\gamma}_{x,y}(h) = \frac{1}{N_h} \sum_{t=h+1}^T (x_t - \bar{x})(y_{t-h} - \bar{y})$ when embedded missing values are present
CCF	$\hat{\rho}_{x,y}(h) = \hat{\gamma}_{x,y}(h) / \sqrt{\hat{\gamma}_x(0)\hat{\gamma}_y(0)}$
CCFSTD	$Std(\hat{\rho}_{x,y}(h)) = 1/\sqrt{N_0}$
CCFNORM	$Norm(\hat{\rho}_{x,y}(h)) = \hat{\rho}_{x,y}(h) / Std(\hat{\rho}_{x,y}(h))$
CCFPROB	$Prob(\hat{\rho}_{x,y}(h)) = 2(1 - \Phi(Norm(\hat{\rho}_{x,y}(h))))$
CCFLPROB	$LogProb(\hat{\rho}_{x,y}(h)) = -\log_{10}(Prob(\hat{\rho}_{x,y}(h)))$
CCF2STD	$Flag(\hat{\rho}_{x,y}(h)) = \begin{cases} 1 & \hat{\rho}_{x,y}(h) > 2Std(\hat{\rho}_{x,y}(h)) \\ 0 & -2Std(\hat{\rho}_{x,y}(h)) < \hat{\rho}_{x,y}(h) < 2Std(\hat{\rho}_{x,y}(h)) \\ -1 & \hat{\rho}_{x,y}(h) < -2Std(\hat{\rho}_{x,y}(h)) \end{cases}$

Spectral Density Analysis

Spectral analysis can be performed on the working series by specifying the OUTSPECTRA= option or by specifying the PLOTS=PERIODOGRAM or PLOTS=SPECTRUM option in the PROC TIMESERIES statement. PROC TIMESERIES uses the finite Fourier transform to decompose data series into a sum of sine and cosine terms of different amplitudes and wavelengths. The Fourier transform decomposition of the series x_t is

$$x_t = \frac{a_0}{2} + \sum_{k=1}^m [a_k \cos(\omega_k t) + b_k \sin(\omega_k t)]$$

where

t	is the time subscript, $t = 1, 2, \dots, n$
x_t	are the equally spaced time series data
n	is the number of observations in the time series
m	is the number of frequencies in the Fourier decomposition: $m = \frac{n}{2}$ if n is even, $m = \frac{n-1}{2}$ if n is odd
a_0	is the mean term: $a_0 = 2\bar{x}$
a_k	are the cosine coefficients
b_k	are the sine coefficients
ω_k	are the Fourier frequencies: $\omega_k = \frac{2\pi k}{n}$

Functions of the Fourier coefficients a_k and b_k can be plotted against frequency or against wave length to form *periodograms*. The amplitude periodogram J_k is defined as follows:

$$J_k = \frac{n}{2}(a_k^2 + b_k^2)$$

The Fourier decomposition is performed after the ACCUMULATE=, DIF=, SDIF= and TRANSFORM= options in the ID and VAR statements have been applied.

Computational Method

If the number of observations, n , factors into prime integers that are less than or equal to 23, and the product of the square-free factors of n is less than 210, then the procedure uses the fast Fourier transform developed by Cooley and Tukey (1965) and implemented by Singleton (1969). If n cannot be factored in this way, then the procedure uses a Chirp-Z algorithm similar to that proposed by Monro and Branch (1976).

Missing Values

Missing values are replaced with an estimate of the mean to perform spectral analyses. This treatment of a series with missing values is consistent with the approach used by Priestley (1981).

Using Specification of Weight Constants

Any number of weighting constants can be specified. The constants are interpreted symmetrically about the middle weight. The middle constant (or the constant to the right of the middle if an even number of weight constants is specified) is the relative weight of the current periodogram ordinate. The constant immediately following the middle one is the relative weight of the next periodogram ordinate, and so on. The actual weights used in the smoothing process are the weights specified in the WEIGHTS option, scaled so that they sum to 1.

The moving average calculation reflects at each end of the periodogram to accommodate the periodicity of the periodogram function.

For example, a simple triangular weighting can be specified using the following WEIGHTS option:

```
spectra / weights 1 2 3 2 1;
```

Using Kernel Specifications

You can specify one of ten different kernels in the SPECTRA statement. The two parameters $c \geq 0$ and $e \geq 0$ are used to compute the bandwidth parameter

$$M = cq^e$$

where q is the number of periodogram ordinates + 1,

$$q = \text{floor}(n/2) + 1$$

To specify the bandwidth explicitly, set $c =$ to the desired bandwidth and $e = 0$.

For example, a Parzen kernel with a support of 11 periodogram ordinates can be specified using the following kernel option:

```
spectra / parzen c=5 expon=0;
```

Kernels are used to smooth the periodogram by using a weighted moving average of nearby points. A smoothed periodogram is defined by the equation

$$\hat{J}_i(M) = \sum_{\tau=-q}^q w\left(\frac{\tau}{M}\right) \tilde{J}_{i+\tau}$$

where $w(x)$ is the kernel or weight function.

At the endpoints, the moving average is computed cyclically; that is,

$$\tilde{J}_{i+\tau} = \begin{cases} J_{i+\tau} & 0 \leq i + \tau \leq q \\ J_{-(i+\tau)} & i + \tau < 0 \\ J_{2q-(i+\tau)} & i + \tau > q \end{cases}$$

where J_i is the i th periodogram ordinate.

The TIMESERIES procedure supports the following kernels:

BART: Bartlett kernel

$$w(x) = \begin{cases} 1 - |x| & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

PARZEN: Parzen kernel

$$w(x) = \begin{cases} 1 - 6|x|^2 + 6|x|^3 & 0 \leq |x| \leq \frac{1}{2} \\ 2(1 - |x|)^3 & \frac{1}{2} \leq |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

QS: quadratic spectral kernel

$$w(x) = \frac{3M^2}{(\pi x)^2} \left(\frac{\sin(\pi x/M)}{\pi x/M} - \cos(\pi x/M) \right)$$

TUKEY: Tukey-Hanning kernel

$$w(x) = \begin{cases} (1 + \cos(\pi x))/2 & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

TRUNCAT: truncated kernel

$$w(x) = \begin{cases} 1 & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

Alternatively, kernel functions can be applied as filters that estimate the autocovariance function in the time domain prior to computing the periodogram by using the DOMAIN=TIME option as

$$\tilde{\gamma}(h) = \lambda(h)\hat{\gamma}(h)$$

where $\lambda(h) = w(h)$. To approximate this operation, complementary kernel weighting functions, $w(\theta)$, can be used to smooth the periodogram by using the same cyclical moving average computation described previously. The frequencies used to weight periodogram ordinates are $\theta = \pi\tau/q$. The five complementary weighting functions available to smooth the periodogram in this manner are:

BART: Bartlett equivalent lag window filter

$$w(\theta) = \frac{1}{2\pi M} \left(\frac{\sin(M\theta/2)}{\sin(\theta/2)} \right)^2$$

PARZEN: Parzen equivalent lag window filter

$$w(\theta) = \frac{6}{\pi M^3} \left(\frac{\sin(M\theta/4)}{\sin(\theta/2)} \right)^4 \left(1 - \frac{2}{3} \sin^2(\theta/2) \right)$$

QS: quadratic spectral equivalent lag window filter

$$w(\theta) = \begin{cases} \frac{3M}{4\pi} (1 - (M\theta/\pi)^2) & |\theta| \leq \pi/M \\ 0 & |\theta| > \pi/M \end{cases}$$

TUKEY: Tukey-Hanning equivalent lag window filter

$$w(\theta) = \frac{1}{4}D_M(\theta - \pi/M) + \frac{1}{2}D_M(\theta) + \frac{1}{4}D_M(\theta + \pi/M)$$

$$D_M(\theta) = \frac{1}{2\pi} \frac{\sin[(M + 1/2)\theta]}{\sin(\theta/2)}$$

TRUNC: truncated equivalent lag window filter

$$w(\theta) = D_M(\theta)$$

Singular Spectrum Analysis

Given a time series, y_t , for $t = 1, \dots, T$, and a window length, $2 \leq L < T/2$, singular spectrum analysis Golyandina, Nekrutkin, and Zhigljavsky (2001) decompose the time series into spectral groupings using the following steps:

Embedding Step

Using the time series, form a $K \times L$ trajectory matrix, \mathbf{X} , with elements

$$\mathbf{X} = \{x_{k,l}\}_{k=1,l=1}^{K,L}$$

such that $x_{k,l} = y_{k-l+1}$ for $k = 1, \dots, K$ and $l = 1, \dots, L$ and where $K = T - L + 1$. By definition $L \leq K < T$, because $2 \leq L < T/2$.

Decomposition Step

Using the trajectory matrix, \mathbf{X} , apply singular value decomposition to the trajectory matrix

$$\mathbf{X} = \mathbf{U}\mathbf{Q}\mathbf{V}$$

where \mathbf{U} represents the $K \times L$ matrix that contains the left-hand-side (LHS) eigenvectors, where \mathbf{Q} represents the diagonal $L \times L$ matrix that contains the singular values, and where \mathbf{V} represents the $L \times L$ matrix that contains the right-hand-side (RHS) eigenvectors.

Therefore,

$$\mathbf{X} = \sum_{l=1}^L \mathbf{X}^{(l)} = \sum_{l=1}^L \mathbf{u}_l q_l \mathbf{v}_l^T$$

where $\mathbf{X}^{(l)}$ represents the $K \times L$ principal component matrix, \mathbf{u}_l represents the $K \times 1$ left-hand-side (LHS) eigenvector, q_l represents the singular value, and \mathbf{v}_l represents the $L \times 1$ right-hand-side (RHS) eigenvector associated with the l th window index.

Grouping Step

For each group index, $m = 1, \dots, M$, define a group of window indices $I_m \subset \{1, \dots, L\}$. Let

$$\mathbf{X}_{I_m} = \sum_{l \in I_m} \mathbf{X}^{(l)} = \sum_{l \in I_m} \mathbf{u}_l q_l \mathbf{v}_l^T$$

represent the grouped trajectory matrix for group I_m . If groupings represent a spectral partition,

$$\bigcup_{m=1}^M I_m = \{1, \dots, L\} \quad \text{and} \quad I_m \cap I_n = \emptyset \quad \text{for} \quad m \neq n$$

then according to the singular value decomposition theory,

$$\mathbf{X} = \sum_{m=1}^M \mathbf{X}_{I_m}$$

Averaging Step

For each group index, $m = 1, \dots, M$, compute the diagonal average of \mathbf{X}_{I_m} ,

$$\tilde{x}_t^{(m)} = \frac{1}{n_t} \sum_{l=s_t}^{e_t} x_{t-l+1,l}^{(m)}$$

where

$$\begin{aligned} s_t = 1, & & e_t = t, & & n_t = t & & \text{for} & & 1 \leq t < L \\ s_t = 1, & & e_t = L, & & n_t = L & & \text{for} & & L \leq t \leq T - L + 1 \\ s_t = T - t - 1, & & e_t = L, & & n_t = T - t + 1 & & \text{for} & & T - L + 1 < t \leq T \end{aligned}$$

If the groupings represent a spectral partition, then by definition

$$y_t = \sum_{m=1}^M \tilde{x}_t^{(m)}$$

Hence, singular spectrum analysis additively decomposes the original time series, y_t , into m component series $\tilde{x}_t^{(m)}$ for $m = 1, \dots, M$.

Specifying the Window Length

You can explicitly specify the maximum window length, $2 \leq L \leq 1000$, using the LENGTH= option or implicitly specify the window length using the INTERVAL= option in the ID statement or the SEASONALITY= option in the PROC TIMESERIES statement.

Either way the window length is reduced based on the accumulated time series length, T , to enforce the requirement that $2 \leq L \leq T/2$.

Specifying the Groups

You can use the GROUPS= option to explicitly specify the composition and number of groups, $I_m \subset \{1, \dots, L\}$ or use the THRESHOLDPCT= option in the SSA statement to implicitly specify the grouping. The THRESHOLDPCT= option is useful for removing noise or less dominant patterns from the accumulated time series.

Let $0 < \alpha < 1$ be the cumulative percent singular value THRESHOLDPCT=. Then the last group, $I_M = \{l_\alpha, \dots, L\}$, is determined by the smallest value such that

$$\left(\frac{\sum_{l=1}^{l_\alpha-1} q_l}{\sum_{l=1}^L q_l} \right) \geq \alpha \quad \text{where } 1 < l_\alpha \leq L$$

Using this rule, the last group, I_M , describes the least dominant patterns in the time series and the size of the last group is at least one and is less than the window length, $L \geq 2$.

Data Set Output

The TIMESERIES procedure can create the OUT=, OUTCORR=, OUTCROSSCORR=, OUTDECOMP=, OUTSEASON=, OUTSPECTRA=, OUTSSA=, OUTSUM=, and OUTTREND= data sets. In general, these data sets contain the variables listed in the BY statement. If an analysis step that is related to an output data step fails, the values of this step are not recorded or are set to missing in the related output data set and appropriate error and/or warning messages are recorded in the log.

OUT= Data Set

The OUT= data set contains the variables specified in the BY, ID, VAR, and CROSSVAR statements. If the ID statement is specified, the ID variable values are aligned and extended based on the ALIGN= and INTERVAL= options. The values of the variables specified in the VAR and CROSSVAR statements are accumulated based on the ACCUMULATE= option, and missing values are interpreted based on the SETMISSING= option.

OUTCORR= Data Set

The OUTCORR= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTCORR= data set records the correlations for each variable specified in a VAR statement (not the CROSSVAR statement).

When the CORR statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to correlation statistics specified in the CORR statement options and the variable *values* are related to the NLAG= or LAGS= option.

NAME	variable name
LAG	time lag
N	number of variance products
ACOV	autocovariances
ACF	autocorrelations
ACFSTD	autocorrelation standard errors
ACF2STD	an indicator of whether autocorrelations are less than (-1), greater than (1), or within (0) two standard errors of zero
ACFNORM	normalized autocorrelations
ACFPROB	autocorrelation probabilities
ACFLPROB	autocorrelation log probabilities
PACF	partial autocorrelations
PACFSTD	partial autocorrelation standard errors
PACF2STD	an indicator of whether partial autocorrelations are less than (-1), greater than (1), or within (0) two standard errors of zero
PACFNORM	partial normalized autocorrelations
PACFPROB	partial autocorrelation probabilities
PACFLPROB	partial autocorrelation log probabilities
IACF	inverse autocorrelations
IACFSTD	an indicator of whether inverse autocorrelations are less than (-1), greater than (1), or within (0) two standard errors of zero

IACF2STD	two standard errors beyond inverse autocorrelation
IACFNORM	normalized inverse autocorrelations
IACFPROB	inverse autocorrelation probabilities
IACFLPROB	inverse autocorrelation log probabilities
WN	white noise test Statistics
WNPROB	white noise test probabilities
WNLPROB	white noise test log probabilities

The preceding correlation statistics are computed for each specified time lag.

When the CORR statement TRANSPOSE=YES option is specified, the variable *values* are related to correlation statistics specified in the CORR statement and the variable *names* are related to the NLAG= or LAGS= options.

<u>_NAME_</u>	variable name
<u>_STAT_</u>	correlation statistic name
<u>_LABEL_</u>	correlation statistic label
LAG h	correlation statistics for lag h

OUTCROSSCORR= Data Set

The OUTCROSSCORR= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTCROSSCORR= data set records the cross-correlations for each variable specified in a VAR and the CROSSVAR statements.

When the CROSSCORR statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to cross-correlation statistics specified in the CROSSCORR statement options and the variable *values* are related to the NLAG= or LAGS= option.

<u>_NAME_</u>	variable name
<u>_CROSS_</u>	cross variable name
LAG	time lag
N	number of variance products
CCOV	cross-covariances
CCF	cross-correlations
CCFSTD	cross-correlation standard errors
CCF2STD	an indicator of whether cross-correlations are less than (-1) , greater than (1) , or within (0) two standard errors of zero
CCFNORM	normalized cross-correlations
CCFPROB	cross-correlation probabilities

CCFLPROB cross-correlation log probabilities

The preceding cross-correlation statistics are computed for each specified time lag.

When the CROSSCORR statement TRANSPOSE=YES option is specified, the variable *values* are related to cross-correlation statistics specified in the CROSSCORR statement and the variable *names* are related to the NLAG= or LAGS= options.

<code>_NAME_</code>	variable name
<code>_CROSS_</code>	cross variable name
<code>_STAT_</code>	cross-correlation statistic name
<code>_LABEL_</code>	cross-correlation statistic label
<code>LAGh</code>	cross-correlation statistics for lag h

OUTDECOMP= Data Set

The OUTDECOMP= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTDECOMP= data set records the seasonal decomposition/adjustments for each variable specified in a VAR statement (not the CROSSVAR statement).

When the DECOMP statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to decomposition/adjustments specified in the DECOMP statement and the variable *values* are related to the ID statement INTERVAL= option and the PROC TIMESERIES statement SEASONALITY= option.

<code>_NAME_</code>	variable name
<code>_MODE_</code>	mode of decomposition
<code>_TIMEID_</code>	time ID values
<code>_SEASON_</code>	seasonal index
ORIGINAL	original series values
TCC	trend-cycle component
SIC	seasonal-irregular component
SC	seasonal component
SCSTD	seasonal component standard errors
TCS	trend-cycle-seasonal component
IC	irregular component
SA	seasonally adjusted series
PCSA	percent change seasonally adjusted series
TC	trend component
CC	cycle component

The preceding decomposition components are computed for each time period.

When the DECOMP statement TRANSPOSE=YES option is specified, the variable *values* are related to decomposition/adjustments specified in the DECOMP statement and the variable *names* are related to the ID statement INTERVAL= option, the PROC TIMESERIES statement SEASONALITY= option, and the DECOMP statement NPERIODS= option.

<code>_NAME_</code>	variable name
<code>_MODE_</code>	mode of decomposition name
<code>_COMP_</code>	decomposition component name
<code>_LABEL_</code>	decomposition component label
<code>PERIODt</code>	decomposition component value for time period t

OUTSEASON= Data Set

The OUTSEASON= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTSEASON= data set records the seasonal statistics for each variable specified in a VAR statement (not the CROSSVAR statement).

When the SEASON statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to seasonal statistics specified in the SEASON statement and the variable *values* are related to the ID statement INTERVAL= option or the PROC TIMESERIES statement SEASONALITY= option.

<code>_NAME_</code>	variable name
<code>_TIMEID_</code>	time ID values
<code>_SEASON_</code>	seasonal index
<code>NOBS</code>	number of observations
<code>N</code>	number of nonmissing observations
<code>NMISS</code>	number of missing observations
<code>MINIMUM</code>	minimum value
<code>MAXIMUM</code>	maximum value
<code>RANGE</code>	maximum value
<code>SUM</code>	summation value
<code>MEAN</code>	mean value
<code>STDDEV</code>	standard deviation
<code>CSS</code>	corrected sum of squares
<code>USS</code>	uncorrected sum of squares
<code>MEDIAN</code>	median value

The preceding statistics are computed for each season.

When the SEASON statement TRANSPOSE=YES option is specified, the variable *values* are related to seasonal statistics specified in the SEASON statement and the variable *names* are related to the ID statement INTERVAL= option or the PROC TIMESERIES statement SEASONALITY= option.

<code>_NAME_</code>	variable name
<code>_STAT_</code>	season statistic name
<code>_LABEL_</code>	season statistic name
<code>SEASONS</code>	season statistic value for season <i>s</i>

OUTSPECTRA= Data Set

The OUTSPECTRA= data set contains the variables that are specified in the BY statement in addition to the variables listed below. The OUTSPECTRA= data set records the frequency domain analysis for each variable specified in a VAR statement (not the CROSSVAR statement).

The following variable names are related to correlation statistics specified in the SPECTRA statement options.

<code>_NAME_</code>	variable name
<code>FREQ</code>	frequency in radians from 0 to π
<code>PERIOD</code>	period or wavelength
<code>COS</code>	cosine transform
<code>SIN</code>	sine transform
<code>P</code>	periodogram
<code>S</code>	spectral density estimates

OUTSSA= Data Set

The OUTSSA= data set contains the variables that are specified in the BY statement in addition to the variables listed below. The OUTSSA= data set records the singular spectrum analysis (SSA) for each variable specified in a VAR statement (not the CROSSVAR statement).

When the SSA statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to singular spectrum analysis specified in the SSA statement, and the variable *values* are related to the INTERVAL= option in the ID statement and the SEASONALITY= option in the PROC TIMESERIES statement.

<code>_NAME_</code>	variable name
<code>_TIMEID_</code>	time ID values
<code>_CYCLE_</code>	cycle index
<code>_SEASON_</code>	seasonal index
<code>ORIGINAL</code>	original series values
<code>_GROUP_i_</code>	SSA result groups

The `_GROUPi_` decomposition components are computed for each time period.

When the SSA statement `TRANSPPOSE=YES` option is specified, the variable *values* are related to singular spectrum analysis specified in the SSA statement, and the variable *names* are related to the `INTERVAL=` option in the ID statement, the `SEASONALITY=` option in the PROC TIMESERIES statement, or the `NPERIODS=` option in the SSA statement. The following variables are written to a transposed `OUTSSA=` data set:

<code>_NAME_</code>	variable name
<code>_GROUP_</code>	group number
<code>PERIOD_t</code>	SSA group value for time period <i>t</i>

OUTSUM= Data Set

The `OUTSUM=` data set contains the variables specified in the BY statement as well as the variables listed below. The `OUTSUM=` data set records the descriptive statistics for each variable specified in a VAR statement (not the `CROSSVAR` statement).

Variables related to descriptive statistics are based on the `ACCUMULATE=` and `SETMISSING=` options in the ID and VAR statements:

<code>_NAME_</code>	variable name
<code>_STATUS_</code>	status flag that indicates whether the requested analyses were successful
<code>NOBS</code>	number of observations
<code>N</code>	number of nonmissing observations
<code>NMISS</code>	number of missing observations
<code>MINIMUM</code>	minimum value
<code>MAXIMUM</code>	maximum value
<code>AVG</code>	average value
<code>STDDEV</code>	standard deviation

The `OUTSUM=` data set contains the descriptive statistics of the (accumulated) time series.

OUTTREND= Data Set

The OUTTREND= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTTREND= data set records the trend statistics for each variable specified in a VAR statement (not the CROSSVAR statement).

When the TREND statement TRANSPOSE=NO option is omitted or explicitly specified, the variable *names* are related to trend statistics specified in the TREND statement and the variable *values* are related to the INTERVAL= option in the ID statement or the SEASONALITY= option in the PROC TIMESERIES statement.

NAME	variable name
TIMEID	time ID values
SEASON	seasonal index
NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
RANGE	maximum value
SUM	summation value
MEAN	mean value
STDDEV	standard deviation
CSS	corrected sum of squares
USS	uncorrected sum of squares
MEDIAN	median value

The preceding statistics are computed for each time period.

When the TREND statement TRANSPOSE=YES option is specified, the variable *values* related to trend statistics specified in the TREND statement and the variable *names* are related to the INTERVAL= option in the ID statement, the SEASONALITY= option in the PROC TIMESERIES statement, or the NPERIODS= option in the TREND statement. The following variables are written to the OUTTREND= data set:

NAME	variable name
STAT	trend statistic name
LABEL	trend statistic name
PERIOD t	trend statistic value for time period t

STATUS Variable Values

The `_STATUS_` variable that appears in the `OUTSUM=` data set contains a code that specifies whether the analysis has been successful or not. The `_STATUS_` variable can take the following values:

0	success
1000	transactional trend statistics failure
2000	transactional seasonal statistics failure
3000	accumulation failure
4000	missing value interpretation failure
6000	series is all missing
7000	transformation failure
8000	differencing failure
9000	unable to compute descriptive statistics
10000	seasonal decomposition failure
11000	correlation analysis failure

Printed Output

The `TIMESERIES` procedure optionally produces printed output by using the Output Delivery System (ODS). By default, the procedure produces no printed output. All output is controlled by the `PRINT=` and `PRINTDETAILS` options associated with the `PROC TIMESERIES` statement. In general, if an analysis step related to printed output fails, the values of this step are not printed and appropriate error or warning messages or both are recorded in the log. The printed output is similar to the output data set, and these similarities are described below.

<code>PRINT=DECOMP</code>	prints the seasonal decomposition similar to the <code>OUTDECOMP=</code> data set.
<code>PRINT=DESCSTATS</code>	prints a table of descriptive statistics for each variable.
<code>PRINT=SEASONS</code>	prints the seasonal statistics similar to the <code>OUTSEASON=</code> data set.
<code>PRINT=SSA</code>	prints the singular spectrum analysis similar to the <code>OUTSSA=</code> data set.
<code>PRINT=SUMMARY</code>	prints the summary statistics similar to the <code>OUTSUM=</code> data set.
<code>PRINT=TRENDS</code>	prints the trend statistics similar to the <code>OUTTREND=</code> data set.
<code>PRINTDETAILS</code>	prints each table with greater detail.

If `PRINT=SEASONS` and the `PRINTDETAILS` options are both specified, all seasonal statistics are printed.

ODS Table Names

Table 29.4 relates the PRINT= options to ODS tables:

Table 29.4 ODS Tables Produced in PROC TIMESERIES

ODS Table Name	Description	Statement	Option
SeasonalDecomposition	Seasonal decomposition	PRINT	DECOMP
DescStats	Descriptive statistics	PRINT	DESCSTATS
GlobalStatistics	Global statistics	PRINT	SEASONS
SeasonStatistics	Season statistics	PRINT	SEASONS
StatisticsSummary	Statistics summary	PRINT	SUMMARY
TrendStatistics	Trend statistics	PRINT	TRENDS
GlobalStatistics	Global statistics	PRINT	TRENDS
SSASingularValues	SSA singular values	PRINT	SSA
SSAResults	SSA results	PRINT	SSA

The tables are related to a single series within a BY group.

ODS Graphics Names

This section describes the graphical output produced by the TIMESERIES procedure. To request these graphs, you must specify the **ODS GRAPHICS ON;** statement in your SAS program before the PROC TIMESERIES step, and you must specify the **PLOTS=** or **CROSSPLOTS=** option in the PROC TIMESERIES statement.

PROC TIMESERIES assigns a name to each graph it creates. These names are listed in Table 29.5.

Table 29.5 ODS Graphics Produced by PROC TIMESERIES

ODS Graph Name	Plot Description	Statement	Option
ACFPlot	Autocorrelation function	PLOTS	ACF
ACFNORMPlot	Normalized autocorrelation function	PLOTS	ACF
CCFNORMPlot	Normalized cross-correlation function	CROSSPLOTS	
			CCF
CCFPlot	Cross-correlation function	CROSSPLOTS

Examples: TIMESERIES Procedure

Example 29.1: Accumulating Transactional Data into Time Series Data

This example illustrates using the TIMESERIES procedure to accumulate time-stamped transactional data that has been recorded at no particular frequency into time series data at a specific frequency. After the time series is created, the various SAS/ETS procedures related to time series analysis, seasonal adjustment/decomposition, modeling, and forecasting can be used to further analyze the time series data.

Suppose that the input data set WORK.RETAIL contains variables STORE and TIMESTAMP and numerous other numeric transaction variables. The BY variable STORE contains values that break up the transactions into groups (BY groups). The time ID variable TIMESTAMP contains SAS date values recorded at no particular frequency. The other data set variables contain the numeric transaction values to be analyzed. It is further assumed that the input data set is sorted by the variables STORE and TIMESTAMP. The following statements form monthly time series from the transactional data based on the median value (ACCUMULATE=MEDIAN) of the transactions recorded with each time period. Also, the accumulated time series values for time periods with no transactions are set to zero instead of to missing (SETMISS=0) and only transactions recorded between the first day of 1998 (START='01JAN1998'D) and last day of 2000 (END='31DEC2000'D) are considered and, if needed, extended to include this range.

```
proc timeseries data=retail out=mseries;
  by store;
  id timestamp interval=month
      accumulate=median
      setmiss=0
      start='01jan1998'd
      end  ='31dec2000'd;
  var _numeric_;
run;
```

The monthly time series data are stored in the data WORK.MSERIES. Each BY group associated with the BY variable STORE contains an observation for each of the 36 months associated with the years 1998, 1999, and 2000. Each observation contains the variable STORE, TIMESTAMP, and each of the analysis variables in the input data set.

After each set of transactions has been accumulated to form corresponding time series, accumulated time series can be analyzed using various time series analysis techniques. For example, exponentially weighted moving averages can be used to smooth each series. The following statements use the EXPAND procedure to smooth the analysis variable named STOREITEM.

```
proc expand data=mseries out=smoothed from=month;
  by store;
  id date;
  convert storeitem=smooth / transform=(ewma 0.1);
run;
```

The smoothed series are stored in the data set WORK.SMOOTHED. The variable SMOOTH contains the smoothed series.

If the time ID variable TIMESTAMP contains SAS datetime values instead of SAS date values, the INTERVAL=, START=, and END= options must be changed accordingly and the following statements could be used:

```
proc timeseries data=retail out=tseries;
  by store;
  id timestamp interval=dtmonth
               accumulate=median
               setmiss=0
               start='01jan1998:00:00:00'dt
               end  ='31dec2000:00:00:00'dt;
  var _numeric_;
run;
```

The monthly time series data are stored in the data WORK.TSERIES, and the time ID values use a SAS datetime representation.

Example 29.2: Trend and Seasonal Analysis

This example illustrates using the TIMESERIES procedure for trend and seasonal analysis of time-stamped transactional data.

Suppose that the data set SASHELP.AIR contains two variables: DATE and AIR. The variable DATE contains sorted SAS date values recorded at no particular frequency. The variable AIR contains the transaction values to be analyzed.

The following statements accumulate the transactional data on an average basis to form a quarterly time series and perform trend and seasonal analysis on the transactions.

```
proc timeseries data=sashelp.air
               out=series
               outtrend=trend
               outseason=season print=seasons;
  id date interval=qtr accumulate=avg;
  var air;
run;
```

The time series is stored in the data set WORK.SERIES, the trend statistics are stored in the data set WORK.TREND, and the seasonal statistics are stored in the data set WORK.SEASON. Additionally, the seasonal statistics are printed (PRINT=SEASONS) and the results of the seasonal analysis are shown in [Output 29.2.1](#).

Output 29.2.1 Seasonal Statistics Table

The TIMESERIES Procedure						
Season Statistics for Variable AIR						
Season Index	N	Minimum	Maximum	Sum	Mean	Standard Deviation
1	36	112.0000	419.0000	8963.00	248.9722	95.65189
2	36	121.0000	535.0000	10207.00	283.5278	117.61839
3	36	136.0000	622.0000	12058.00	334.9444	143.97935
4	36	104.0000	461.0000	9135.00	253.7500	101.34732

Using the trend statistics stored in the WORK.TREND data set, the following statements plot various trend statistics associated with each time period over time.

```

title1 "Trend Statistics";
proc sgplot data=trend;
  series x=date y=max / lineattrs=(pattern=solid);
  series x=date y=mean / lineattrs=(pattern=solid);
  series x=date y=min / lineattrs=(pattern=solid);
  yaxis display=(nolabel);
  format date year4.;
run;

```

The results of this trend analysis are shown in [Output 29.2.2](#).

Output 29.2.2 Trend Statistics Plot

Using the trend statistics stored in the WORK.TREND data set, the following statements chart the sum of the transactions associated with each time period for the second season over time.

```

title1 "Trend Statistics for 2nd Season";
proc sgplot data=trend;
  where _season_ = 2;
  vbar date / freq=sum;
  format date year4.;
  yaxis label='Sum';
run;

```

The results of this trend analysis are shown in [Output 29.2.3](#).

Output 29.2.3 Trend Statistics Bar Chart

Using the trend statistics stored in the WORK.TREND data set, the following statements plot the mean of the transactions associated with each time period by each year over time.

```
data trend;
  set trend;
  year = year(date);
run;

title1 "Trend Statistics by Year";
proc sgplot data=trend;
  series x=_season_ y=mean / group=year lineattrs=(pattern=solid);
  xaxis values=(1 to 4 by 1);
run;
```

The results of this trend analysis are shown in [Output 29.2.4](#).

Output 29.2.4 Trend Statistics

Using the season statistics stored in the WORK.SEASON data set, the following statements plot various season statistics for each season.

```

title1 "Seasonal Statistics";
proc sgplot data=season;
  series x=_season_ y=max / lineattrs=(pattern=solid);
  series x=_season_ y=mean / lineattrs=(pattern=solid);
  series x=_season_ y=min / lineattrs=(pattern=solid);
  yaxis display=(nolabel);
  xaxis values=(1 to 4 by 1);
run;

```

The results of this seasonal analysis are shown in [Output 29.2.5](#).

Output 29.2.5 Seasonal Statistics Plot

Example 29.3: Illustration of ODS Graphics

This example illustrates the use of ODS graphics.

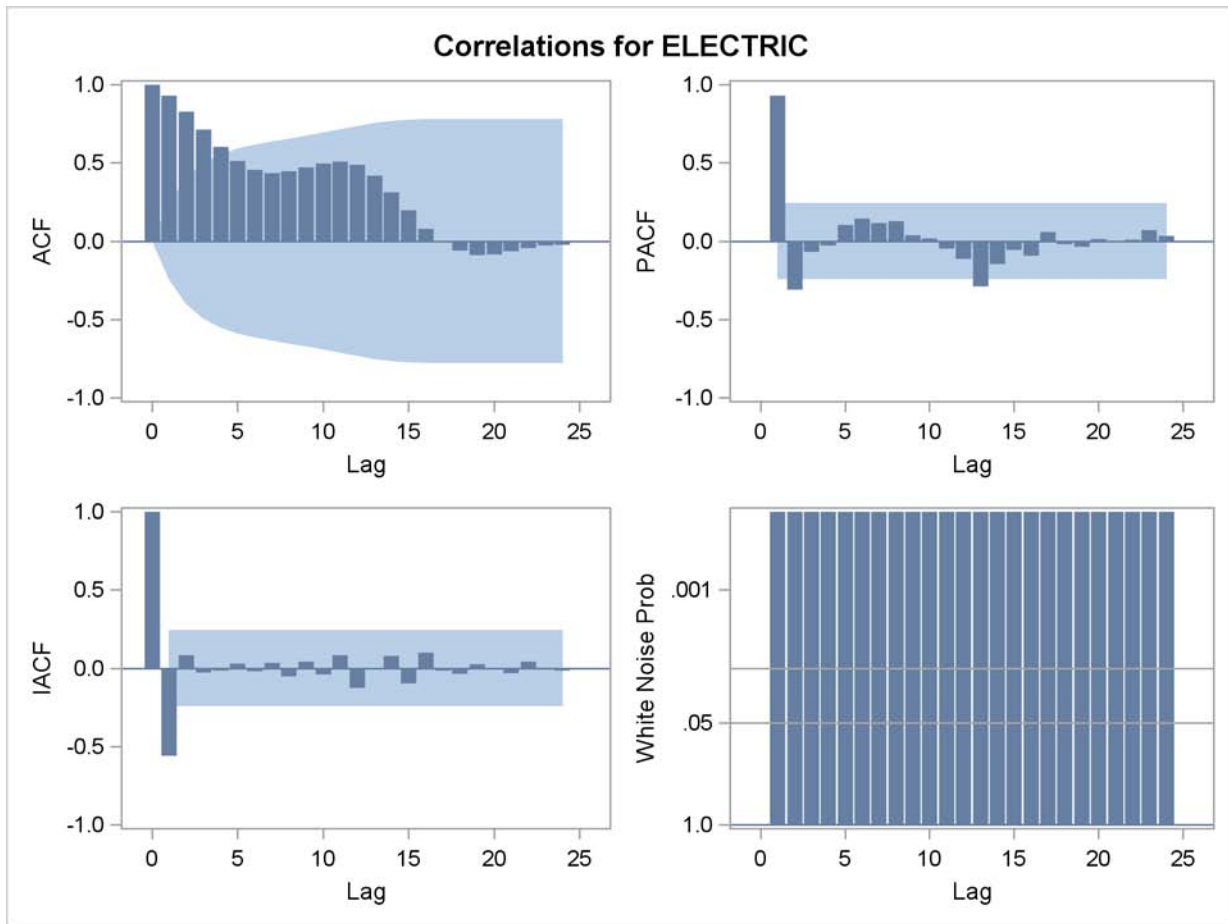

The following statements use the SASHELP.WORKERS data set to study the time series of electrical workers and its interaction with the simply differenced series of masonry workers. The series plot, the correlation panel, the seasonal adjustment panel, and all cross-series plots are requested. [Output 29.3.1](#) through [Output 29.3.4](#) show a selection of the plots created.

The graphical displays are requested by specifying the ODS GRAPHICS statement and the PLOTS= or CROSSPLOTS= options in the PROC TIMESERIES statement. For information about the graphics available in the TIMESERIES procedure, see the section “[ODS Graphics Names](#)” on page 1899.

```
title "Illustration of ODS Graphics";  
proc timeseries data=sashelp.workers out=_null_  
    plots=(series corr decomp)  
    crossplots=all;  
    id date interval=month;  
    var electric;  
    crossvar masonry / dif=(1);  
run;
```

Output 29.3.1 Series Plot

Output 29.3.2 Correlation Panel

Output 29.3.3 Seasonal Decomposition Panel

Output 29.3.4 Cross-Correlation Plot**Example 29.4: Illustration of Spectral Analysis**

This example illustrates the use of spectral analysis.

The following statements perform a spectral analysis on the SUNSPOT dataset. The periodogram and estimated spectral density are displayed as a function of the period in [Output 29.4.1](#) and frequency in [Output 29.4.2](#).

```

title "Wolfer's Sunspot Data";

proc timeseries data=sunspot plot=(series spectrum);
  var wolfer;
  id year interval=year;

Overview: The TSCSREG Procedure

The TSCSREG (time series cross section regression) procedure analyzes a class of linear econometric models that commonly arise when time series and cross-sectional data are combined. The TSCSREG procedure deals with panel data sets that consist of time series observations on each of several cross-sectional units.

The TSCSREG procedure is very similar to the PANEL procedure; for full description, syntax details, models, and estimation methods, see Chapter 19, “[The PANEL Procedure](#).” The TSCSREG procedure is no longer being updated, and it shares the code base with the PANEL procedure.

Getting Started: The TSCSREG Procedure

Specifying the Input Data

The input data set used by the TSCSREG procedure must be sorted by cross section and by time within each cross section. Therefore, the first step in using PROC TSCSREG is to make sure that the input data set is sorted. Normally, the input data set contains a variable that identifies the cross section for each observation and a variable that identifies the time period for each observation.

To illustrate, suppose that you have a data set A that contains data over time for each of several states. You want to regress the variable Y on regressors X1 and X2. Cross sections are identified by the variable STATE, and time periods are identified by the variable DATE. The following statements sort the data set A appropriately:

```
proc sort data=a;  
  by state date;  
run;
```

The next step is to invoke the TSCSREG procedure and specify the cross section and time series variables in an ID statement. List the variables in the ID statement exactly as they are listed in the BY statement.

```
proc tscsreg data=a;  
  id state date;
```

Alternatively, you can omit the ID statement and use the CS= and TS= options on the PROC TSCSREG statement to specify the number of cross sections in the data set and the number of time series observations in each cross section.

Unbalanced Data

In the case of fixed-effects and random-effects models, the TSCSREG procedure is capable of processing data with different numbers of time series observations across different cross sections. You must specify the ID statement to estimate models that use unbalanced data. The missing time series observations are recognized by the absence of time series ID variable values in some of the cross sections in the input data set. Moreover, if an observation with a particular time series ID value and cross-sectional ID value is present in the input data set, but one or more of the model variables are missing, that time series point is treated as missing for that cross section.

Specifying the Regression Model

Next, specify the linear regression model with a MODEL statement, as shown in the following statements.

```
proc tscsreg data=a;
  id state date;
  model y = x1 x2;
run;
```

The MODEL statement in PROC TSCSREG is specified like the MODEL statement in other SAS regression procedures: the dependent variable is listed first, followed by an equal sign, followed by the list of regressor variables.

The reason for using PROC TSCSREG instead of other SAS regression procedures is that you can incorporate a model for the structure of the random errors. It is important to consider what kind of error structure model is appropriate for your data and to specify the corresponding option in the MODEL statement.

The error structure options supported by the TSCSREG procedure are FIXONE, FIXTWO, RANONE, RANTWO, FULLER, PARKS, and DASILVA. See “[Details: The TSCSREG Procedure](#)” on page 1930 for more information about these methods and the error structures they assume.

By default, the two-way random-effects error model structure is used while Fuller-Battese and Wansbeek-Kapteyn methods are used for the estimation of variance components in balanced data and unbalanced data, respectively. Thus, the preceding example is the same as specifying the RANTWO option, as shown in the following statements:

```
proc tscsreg data=a;
  id state date;
  model y = x1 x2 / rantwo;
run;
```

You can specify more than one error structure option in the MODEL statement; the analysis is repeated using each method specified. You can use any number of MODEL statements to estimate different regression models or estimate the same model by using different options.

In order to aid in model specification within this class of models, the procedure provides two specification test statistics. The first is an F statistic that tests the null hypothesis that the fixed-effects parameters are all zero. The second is a Hausman m -statistic that provides information about the appropriateness of the random-effects specification. It is based on the idea that, under the null hypothesis of no correlation between the effects variables and the regressors, OLS and GLS are consistent, but OLS is inefficient. Hence, a test can be based on the result that the covariance of an efficient estimator with its difference from an inefficient estimator is zero. Rejection of the null hypothesis might suggest that the fixed-effects model is more appropriate.

The procedure also provides the Buse R-square measure, which is the most appropriate goodness-of-fit measure for models estimated by using GLS. This number is interpreted as a measure of the

proportion of the transformed sum of squares of the dependent variable that is attributable to the influence of the independent variables. In the case of OLS estimation, the Buse R-square measure is equivalent to the usual R-square measure.

Estimation Techniques

If the effects are fixed, the models are essentially regression models with dummy variables that correspond to the specified effects. For fixed-effects models, ordinary least squares (OLS) estimation is equivalent to best linear unbiased estimation.

The output from TSCSREG is identical to what one would obtain from creating dummy variables to represent the cross-sectional and time (fixed) effects. The output is presented in this manner to facilitate comparisons to the least squares dummy variables estimator (LSDV). As such, the inclusion of an intercept term implies that one dummy variable must be dropped. The actual estimation of the fixed-effects models is not LSDV. LSDV is much too cumbersome to implement. Instead, TSCSREG operates in a two step fashion. In the first step, the following occurs:

- *One-way fixed-effects model:* In the one-way fixed-effects model, the data is transformed by removing the cross-sectional means from the dependent and independent variables. The following is true:

$$\tilde{y}_{it} = y_{it} - \bar{y}_i$$

$$\tilde{\mathbf{x}}_{it} = \mathbf{x}_{it} - \bar{\mathbf{x}}_i$$

- *Two-way fixed-effects model:* In the two-way fixed-effects model, the data is transformed by removing the cross-sectional and time means and adding back the overall means:

$$\tilde{y}_{it} = y_{it} - \bar{y}_i - \bar{y}_t + \bar{\bar{y}}$$

$$\tilde{\mathbf{x}}_{it} = \mathbf{x}_{it} - \bar{\mathbf{x}}_i - \bar{\mathbf{x}}_t + \bar{\bar{\mathbf{x}}}$$

where the symbols:

y_{it} and \mathbf{x}_{it} are the dependent variable (a scalar) and the explanatory variables (a vector whose columns are the explanatory variables not including a constant), respectively

\bar{y}_i and $\bar{\mathbf{x}}_i$ are cross section means

\bar{y}_t and $\bar{\mathbf{x}}_t$ are time means

$\bar{\bar{y}}$ and $\bar{\bar{\mathbf{x}}}$ are the overall means

The second step consists of running OLS on the properly demeaned series, provided that the data are balanced. The unbalanced case is slightly more difficult, because the structure of the missing data must be retained. For this case, PROC TSCSREG uses a slight specialization on Wansbeek and Kapteyn.

The other alternative is to assume that the effects are random. In the one-way case, $E(v_i) = 0$, $E(v_i^2) = \sigma_v^2$, and $E(v_i v_j) = 0$ for $i \neq j$, and v_i is uncorrelated with ϵ_{it} for all i and t . In the two-way case, in addition to all of the preceding, $E(e_t) = 0$, $E(e_t^2) = \sigma_e^2$, and $E(e_t e_s) = 0$ for $t \neq s$, and the e_t are uncorrelated with the v_i and the ϵ_{it} for all i and t . Thus, the model is a variance components model, with the variance components σ_v^2 , σ_e^2 , and σ_ϵ^2 , to be estimated. A crucial implication of such a specification is that the effects are independent of the regressors. For random-effects models, the estimation method is an estimated generalized least squares (EGLS) procedure that involves estimating the variance components in the first stage and using the estimated variance covariance matrix thus obtained to apply generalized least squares (GLS) to the data.

Introductory Example

The following example uses the cost function data from Greene (1990) to estimate the variance components model. The variable OUTPUT is the log of output in millions of kilowatt-hours, and COST is the log of cost in millions of dollars. Refer to Greene (1990) for details.

```

title1;
data greene;
  input firm year output cost @@;
  df1 = firm = 1;
  df2 = firm = 2;
  df3 = firm = 3;
  df4 = firm = 4;
  df5 = firm = 5;
  d60 = year = 1960;
  d65 = year = 1965;
  d70 = year = 1970;
datalines;

... more lines ...

```

Usually you cannot explicitly specify all the explanatory variables that affect the dependent variable. The omitted or unobservable variables are summarized in the error disturbances. The TSCSREG procedure used with the RANTWO option specifies the two-way random-effects error model where the variance components are estimated by the Fuller-Battese method, because the data are balanced and the parameters are efficiently estimated by using the GLS method. The variance components model used by the Fuller-Battese method is

$$y_{it} = \sum_{k=1}^K X_{itk} \beta_k + v_i + e_t + \epsilon_{it} \quad i = 1, \dots, N; t = 1, \dots, T$$

The following statements fit this model.

```

proc sort data=greene;
  by firm year;
run;

```

```

proc tscsreg data=greene;
  model cost = output / rantwo;
  id firm year;
run;

```

The TSCSREG procedure output is shown in [Figure 30.1](#). A model description is printed first; it reports the estimation method used and the number of cross sections and time periods. The variance components estimates are printed next. Finally, the table of regression parameter estimates shows the estimates, standard errors, and t tests.

Syntax: The TSCSREG Procedure

The following statements are used with the TSCSREG procedure.

```

PROC TSCSREG options ;
  BY variables ;
  ID cross-section-id-variable time-series-id-variable ;
  MODEL dependent = regressor-variables / options ;
  TEST equation1 <,equation2... > ;

```

Functional Summary

The statements and options used with the TSCSREG procedure are summarized in the following table.

Table 30.1 Functional Summary

Description	Statement	Option
Data Set Options		
specify the input data set	TSCSREG	DATA=
write parameter estimates to an output data set	TSCSREG	OUTEST=
include correlations in the OUTEST= data set	TSCSREG	CORROUT
include covariances in the OUTEST= data set	TSCSREG	COVOUT
specify number of time series observations	TSCSREG	TS=
specify number of cross sections	TSCSREG	CS=
Declaring the Role of Variables		
specify BY-group processing	BY	
specify the cross section and time ID variables	ID	
Printing Control Options		
print correlations of the estimates	MODEL	CORRB
print covariances of the estimates	MODEL	COVB
suppress printed output	MODEL	NOPRINT
perform tests of linear hypotheses	TEST	
Model Estimation Options		
specify the one-way fixed-effects model	MODEL	FIXONE
specify the two-way fixed-effects model	MODEL	FIXTWO
specify the one-way random-effects model	MODEL	RANONE
specify the two-way random-effects model	MODEL	RANTWO
specify Fuller-Battese method	MODEL	FULLER
specify PARKS	MODEL	PARKS

Description	Statement	Option
specify Da Silva method	MODEL	DASILVA
specify order of the moving-average error process for Da Silva method	MODEL	M=
print Φ matrix for Parks method	MODEL	PHI
print autocorrelation coefficients for Parks method	MODEL	RHO
suppress the intercept term	MODEL	NOINT
control check for singularity	MODEL	SINGULAR=

PROC TSCSREG Statement

PROC TSCSREG *options* ;

The following options can be specified in the PROC TSCSREG statement.

DATA=*SAS-data-set*

names the input data set. The input data set must be sorted by cross section and by time period within cross section. If you omit the DATA= option, the most recently created SAS data set is used.

TS=*number*

specifies the number of observations in the time series for each cross section. The TS= option value must be greater than 1. The TS= option is required unless an ID statement is used. Note that the number of observations for each time series must be the same for each cross section and must cover the same time period.

CS=*number*

specifies the number of cross sections. The CS= option value must be greater than 1. The CS= option is required unless an ID statement is used.

OUTEST=*SAS-data-set*

the parameter estimates. When the OUTEST= option is not specified, the OUTEST= data set is not created.

OUTCOV

COVOUT

writes the covariance matrix of the parameter estimates to the OUTEST= data set.

OUTCORR

CORROUT

writes the correlation matrix of the parameter estimates to the OUTEST= data set.

In addition, any of the following MODEL statement options can be specified in the PROC TSCSREG statement: CORRB, COVB, FIXONE, FIXTWO, RANONE, RANTWO, FULLER,

PARKS, DASILVA, NOINT, NOPRINT, M=, PHI, RHO, and SINGULAR=. When specified in the PROC TSCSREG statement, these options are equivalent to specifying the options for every MODEL statement.

BY Statement

BY *variables* ;

A BY statement can be used with PROC TSCSREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the input data set must be sorted by the BY variables as well as by cross section and time period within the BY groups.

When both an ID statement and a BY statement are specified, the input data set must be sorted first with respect to BY variables and then with respect to the cross section and time series ID variables. For example,

```
proc sort data=a;
    by byvar1 byvar2 csid tsid;
run;

proc tscsreg data=a;
    by byvar1 byvar2;
    id csid tsid;
    ...
run;
```

When both a BY statement and an ID statement are used, the data set might have a different number of cross sections or a different number of time periods in each BY group. If no ID statement is used, the CS= N and TS= T options must be specified and each BY group must contain $N \times T$ observations.

ID Statement

ID *cross-section-id-variable time-series-id-variable* ;

The ID statement is used to specify variables in the input data set that identify the cross section and time period for each observation.

When an ID statement is used, the TSCSREG procedure verifies that the input data set is sorted by the cross section ID variable and by the time series ID variable within each cross section. The TSCSREG procedure also verifies that the time series ID values are the same for all cross sections.

To make sure the input data set is correctly sorted, use PROC SORT with a BY statement with the variables listed exactly as they are listed in the ID statement to sort the input data set. For example,

```
proc sort data=a;
```

```

    by csid tsid;
run;

proc tscsreg data=a;
    id csid tsid;
    ... etc. ...
run;

```

If the ID statement is not used, the TS= and CS= options must be specified on the PROC TSCSREG statement. Note that the input data must be sorted by time within cross section, regardless of whether the cross section structure is given by an ID statement or by the options TS= and CS=.

If an ID statement is specified, the time series length T is set to the minimum number of observations for any cross section, and only the first T observations in each cross section are used. If both the ID statement and the TS= and CS= options are specified, the TS= and CS= options are ignored.

MODEL Statement

MODEL *response = regressors / options ;*

The MODEL statement specifies the regression model and the error structure assumed for the regression residuals. The response variable on the left side of the equal sign is regressed on the independent variables listed after the equal sign. Any number of MODEL statements can be used. For each model statement, only one response variable can be specified on the left side of the equal sign.

The error structure is specified by the FIXONE, FIXTWO, RANONE, RANTWO, FULLER, PARKS, and DASILVA options. More than one of these options can be used, in which case the analysis is repeated for each error structure model specified.

Models can be given labels up to 32 characters in length. Model labels are used in the printed output to identify the results for different models. If no label is specified, the response variable name is used as the label for the model. The model label is specified as follows:

label: **MODEL** *response = regressors / options ;*

The following options can be specified on the MODEL statement after a slash (/).

CORRB

CORR

prints the matrix of estimated correlations between the parameter estimates.

COVB

VAR

prints the matrix of estimated covariances between the parameter estimates.

FIXONE

specifies that a one-way fixed-effects model be estimated with the one-way model that corresponds to group effects only.

FIXTWO

specifies that a two-way fixed-effects model be estimated.

RANONE

specifies that a one-way random-effects model be estimated.

RANTWO

specifies that a two-way random-effects model be estimated.

FULLER

specifies that the model be estimated by using the Fuller-Battese method, which assumes a variance components model for the error structure.

PARKS

specifies that the model be estimated by using the Parks method, which assumes a first-order autoregressive model for the error structure.

DASILVA

specifies that the model be estimated by using the Da Silva method, which assumes a mixed variance-component moving-average model for the error structure.

M=number

specifies the order of the moving-average process in the Da Silva method. The M= value must be less than $T - 1$. The default is M=1.

PHI

prints the Φ matrix of estimated covariances of the observations for the Parks method. The PHI option is relevant only when the PARKS option is used.

RHO

prints the estimated autocorrelation coefficients for the Parks method.

NOINT**NOMEAN**

suppresses the intercept parameter from the model.

NOPRINT

suppresses the normal printed output.

SINGULAR=number

specifies a singularity criterion for the inversion of the matrix. The default depends on the precision of the computer system.

TEST Statement

TEST *equation* < , *equation* ... > < / *options* > ;

The TEST statement performs F tests of linear hypotheses about the regression parameters in the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. All hypotheses in one TEST statement are tested jointly. Variable names in the equations must correspond to regressors in the preceding MODEL statement, and each name represents the coefficient of the corresponding regressor. The keyword INTERCEPT refers to the coefficient of the intercept.

The following statements illustrate the use of the TEST statement:

```
proc tscsreg;
  model y = x1 x2 x3;
  test x1 = 0, x2 * .5 + 2 * x3 = 0;
  test_int: test intercept=0, x3 = 0;
```

Note that a test of the following form is not permitted:

```
test_bad: test x2 / 2 + 2 * x3 = 0;
```

Do not use the division sign in test/restrict statements.

Details: The TSCSREG Procedure

Models, estimators, and methods are covered in detail in Chapter 19, “The PANEL Procedure.”

ODS Table Names

PROC TSCSREG assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 30.2 ODS Tables Produced in PROC TSCSREG

ODS Table Name	Description	Option
ODS Tables Created by the MODEL Statement		
ModelDescription	Model description	default
FitStatistics	Fit statistics	default
FixedEffectsTest	F test for no fixed effects	FIXONE, FIXTWO, RA- NONE, RANTWO
ParameterEstimates	Parameter estimates	default
CovB	Covariance of parameter estimates	COVB
CorrB	Correlations of parameter estimates	CORRB

Table 30.2 continued

ODS Table Name	Description	Option
VarianceComponents	Variance component estimates	FULLER, DASILVA, M=, RANONE, RANTWO
RandomEffectsTest	Hausman test for random effects	FULLER, DASILVA, M=, RANONE, RANTWO
AR1Estimates	First order autoregressive parameter estimates	PARKS, RHO
EstimatedPhiMatrix	Estimated phi matrix	PARKS
EstimatedAutocovariances	Estimates of autocovariances	DASILVA, M=
ODS Tables Created by the TEST Statement		
TestResults	Test results	

Examples: The TSCSREG Procedure

For examples of analysis of panel data, see Chapter 19, “The PANEL Procedure.”

Acknowledgments: TSCSREG Procedure

The original TSCSREG procedure was developed by Douglas J. Drummond and A. Ronald Gallant, and contributed to the Version 5 SUGI Supplemental Library in 1979. The original code was changed substantially over the years. Additional new methods as well as other new features are currently included in the PANEL PROCEDURE. SAS Institute would like to thank Dr. Drummond and Dr. Gallant for their contribution of the original version of the TSCSREG procedure.

Overview: UCM Procedure

The UCM procedure analyzes and forecasts equally spaced univariate time series data by using an unobserved components model (UCM). The UCMs are also called *structural models* in the time series literature. A UCM decomposes the response series into components such as trend, seasonals, cycles, and the regression effects due to predictor series. The components in the model are supposed to capture the salient features of the series that are useful in explaining and predicting its behavior. Harvey (1989) is a good reference for time series modeling that uses the UCMs. Harvey calls the components in a UCM the “stylized facts” about the series under consideration. Traditionally, the ARIMA models and, to some limited extent, the exponential smoothing models have been the main tools in the analysis of this type of time series data. It is fair to say that the UCMs capture the versatility of the ARIMA models while possessing the interpretability of the smoothing models. A thorough discussion of the correspondence between the ARIMA models and the UCMs, and the relative merits of UCM and ARIMA modeling, is given in Harvey (1989). The UCMs are also very similar to another set of models, called the *dynamic models*, that are popular in the Bayesian time series literature (West and Harrison 1999). In SAS/ETS you can use PROC ARIMA for ARIMA modeling (see Chapter 7, “The ARIMA Procedure”), PROC ESM for exponential smoothing modeling (see Chapter 13, “The ESM Procedure”), and use the Time Series Forecasting System for a point-and-click interface to ARIMA and exponential smoothing modeling.

You can use the UCM procedure to fit a wide range of UCMs that can incorporate complex trend, seasonal, and cyclical patterns and can include multiple predictors. It provides a variety of diagnostic tools to assess the fitted model and to suggest the possible extensions or modifications. The components in the UCM provide a succinct description of the underlying mechanism governing the series. You can print, save, or plot the estimates of these component series. Along with the standard forecast and residual plots, the study of these component plots is an essential part of time series analysis using the UCMs. Once a suitable UCM is found for the series under consideration, it can be used for a variety of purposes. For example, it can be used for the following:

- forecasting the values of the response series and the component series in the model
- obtaining a model-based seasonal decomposition of the series
- obtaining a “denoised” version and interpolating the missing values of the response series in the historical period
- obtaining the full sample or “smoothed” estimates of the component series in the model

Getting Started: UCM Procedure

The analysis of time series using the UCMs involves recognizing the salient features present in the series and modeling them suitably. The UCM procedure provides a variety of models for estimating and forecasting the commonly observed features in time series. These models are discussed in detail later in the section “An Introduction to Unobserved Component Models” on page 1973. First the procedure is illustrated using an example.

A Seasonal Series with Linear Trend

The airline passenger series, given as Series G in Box and Jenkins (1976), is often used in time series literature as an example of a nonstationary seasonal time series. This series is a monthly series consisting of the number of airline passengers who traveled during the years 1949 to 1960. Its main features are a steady rise in the number of passengers from year to year and the seasonal variation in the numbers during any given year. It also exhibits an increase in variability around the trend. A log transformation is used to stabilize this variability. The following DATA step prepares the log-transformed passenger series analyzed in this example:

```
data seriesG;
  set sashelp.air;
  logair = log( air );
run;
```

The following statements produce a time series plot of the series by using the TIMESERIES procedure (see Chapter 29, “The TIMESERIES Procedure”). The trend and seasonal features of the series are apparent in the plot in [Figure 31.1](#).

```
ods graphics on;
proc timeseries data=seriesG plot=series;
  id date interval=month;
  var logair;
run;
```

Figure 31.1 Series Plot of Log-Transformed Airline Passenger Series

In this example this series is modeled using an unobserved component model called the basic structural model (BSM). The BSM models a time series as a sum of three stochastic components: a trend component μ_t , a seasonal component γ_t , and random error ϵ_t . Formally, a BSM for a response series y_t can be described as

$$y_t = \mu_t + \gamma_t + \epsilon_t$$

Each of the stochastic components in the model is modeled separately. The random error ϵ_t , also called the *irregular component*, is modeled simply as a sequence of independent, identically distributed (i.i.d.) zero-mean Gaussian random variables. The trend and the seasonal components can be modeled in a few different ways. The model for trend used here is called a *locally linear time trend*. This trend model can be written as follows:

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim i.i.d. N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim i.i.d. N(0, \sigma_\xi^2) \end{aligned}$$

These equations specify a trend where the level μ_t as well as the slope β_t is allowed to vary over time. This variation in slope and level is governed by the variances of the disturbance terms η_t and ξ_t in their respective equations. Some interesting special cases of this model arise when you manipulate

these disturbance variances. For example, if the variance of ξ_t is zero, the slope will be constant (equal to β_0); if the variance of η_t is also zero, μ_t will be a deterministic trend given by the line $\mu_0 + \beta_0 t$. The seasonal model used in this example is called a trigonometric seasonal. The stochastic equations governing a trigonometric seasonal are explained later (see the section “Modeling Seasons” on page 1975). However, it is interesting to note here that this seasonal model reduces to the familiar regression with deterministic seasonal dummies if the variance of the disturbance terms in its equations is equal to zero. The following statements specify a BSM with these three components:

```
proc ucm data=seriesG;
  id date interval=month;
  model logair;
  irregular;
  level;
  slope;
  season length=12 type=trig print=smooth;
  estimate;
  forecast lead=24 print=decomp;
run;
```

The PROC UCM statement signifies the start of the UCM procedure, and the input data set, seriesG, containing the dependent series is specified there. The optional ID statement is used to specify a date, datetime, or time identification variable, date in this example, to label the observations. The INTERVAL=MONTH option in the ID statement indicates that the measurements were collected on a monthly basis. The model specification begins with the MODEL statement, where the response series is specified (logair in this case). After this the components in the model are specified using separate statements that enable you to control their individual properties. The irregular component ϵ_t is specified using the IRREGULAR statement and the trend component μ_t is specified using the LEVEL and SLOPE statements. The seasonal component γ_t is specified using the SEASON statement. The specifics of the seasonal characteristics such as the season length, its stochastic evolution properties, etc., are specified using the options in the SEASON statement. The seasonal component used in this example has a season length of 12, corresponding to the monthly seasonality, and is of the *trigonometric* type. Different types of seasonals are explained later (see the section “Modeling Seasons” on page 1975).

The parameters of this model are the variances of the disturbance terms in the evolution equations of μ_t , β_t , and γ_t and the variance of the irregular component ϵ_t . These parameters are estimated by maximizing the likelihood of the data. The ESTIMATE statement options can be used to specify the span of data used in parameter estimation and to display and save the results of the estimation step and the model diagnostics. You can use the estimated model to obtain the forecasts of the series as well as the components. The options in the individual component statements can be used to display the component forecasts—for example, PRINT=SMOOTH option in the SEASON statement requests the displaying of smoothed forecasts of the seasonal component γ_t . The series forecasts and forecasts of the sum of components can be requested using the FORECAST statement. The option PRINT=DECOMP in the FORECAST statement requests the printing of the smoothed trend μ_t and the trend plus seasonal component ($\mu_t + \gamma_t$).

The parameter estimates for this model are displayed in Figure 31.2.

Figure 31.2 BSM for the Logair Series

The UCM Procedure					
Final Estimates of the Free Parameters					
Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > t
Irregular	Error Variance	0.00023436	0.0001079	2.17	0.0298
Level	Error Variance	0.00029828	0.0001057	2.82	0.0048
Slope	Error Variance	8.47911E-13	6.2271E-10	0.00	0.9989
Season	Error Variance	0.00000356	1.32347E-6	2.69	0.0072

The estimates suggest that except for the slope component, the disturbance variances of all the components are significant—that is, all these components are *stochastic*. The slope component, however, appears to be deterministic because its error variance is quite insignificant. It might then be useful to check if the slope component can be dropped from the model—that is, if $\beta_0 = 0$. This can be checked by examining the significance analysis table of the components given in Figure 31.3.

Figure 31.3 Component Significance Analysis for the Logair Series

Significance Analysis of Components (Based on the Final State)			
Component	DF	Chi-Square	Pr > ChiSq
Irregular	1	0.08	0.7747
Level	1	117867	<.0001
Slope	1	43.78	<.0001
Season	11	507.75	<.0001

This table provides the significance of the components in the model at the end of the estimation span. If a component is deterministic, this analysis is equivalent to checking whether the corresponding regression effect is significant. However, if a component is stochastic, then this analysis pertains only to the portion of the series near the end of the estimation span. In this example the slope appears quite significant and should be retained in the model, possibly as a deterministic component. Note that, on the basis of this table, the irregular component's contribution appears insignificant toward the end of the estimation span; however, since it is a stochastic component, it cannot be dropped from the model on the basis of this analysis alone. The slope component can be made deterministic by holding the value of its error variance fixed at zero. This is done by modifying the SLOPE statement as follows:

```
slope variance=0 noest;
```

After a tentative model is fit, its adequacy can be checked by examining different goodness-of-fit measures and other diagnostic tests and plots that are based on the model residuals. Once the model appears satisfactory, it can be used for forecasting. An interesting feature of the UCM procedure is that, apart from the series forecasts, you can request the forecasts of the individual components in the

model. The plots of component forecasts can be useful in understanding their contributions to the series. In order to obtain the plots, you need to turn ODS Graphics on by using the `ODS GRAPHICS ON;` statement. The following statements illustrate some of these features:

```
ods graphics on;

proc ucm data=seriesG;
  id date interval = month;
  model logair;
  irregular;
  level plot=smooth;
  slope variance=0 noest;
  season length=12 type=trig
    plot=smooth;
  estimate;
  forecast lead=24 plot=decomp;
run;
```

The table given in [Figure 31.4](#) shows the goodness-of-fit statistics that are computed by using the one-step-ahead prediction errors (see the section “[Statistics of Fit](#)” on page 2011). These measures indicate a good agreement between the model and the data. Additional diagnostic measures are also printed by default but are not shown here.

Figure 31.4 Fit Statistics for the Logair Series

The UCM Procedure	
Fit Statistics Based on Residuals	
Mean Squared Error	0.00147
Root Mean Squared Error	0.03830
Mean Absolute Percentage Error	0.54132
Maximum Percent Error	2.19097
R-Square	0.99061
Adjusted R-Square	0.99046
Random Walk R-Square	0.87288
Amemiya's Adjusted R-Square	0.99017
Number of non-missing residuals used for computing the fit statistics = 131	

The first plot, shown in [Figure 31.5](#), is produced by the `PLOT=SMOOTH` option in the `LEVEL` statement, it shows the smoothed level of the series.

Figure 31.5 Smoothed Trend in the Logair Series

The second plot (Figure 31.6), produced by the PLOT=SMOOTH option in the SEASON statement, shows the smoothed seasonal component by itself.

Figure 31.6 Smoothed Seasonal in the Logair Series

The plot of the sum of the trend and seasonal component, produced by the PLOT=DECOMP option in the FORECAST statement, is shown in Figure 31.7. You can see that, at least visually, the model seems to fit the data well. In all these decomposition plots the component estimates are extrapolated for two years in the future based on the LEAD=24 option specified in the FORECAST statement.

Figure 31.7 Smoothed Trend plus Seasonal in the Logair Series

Syntax: UCM Procedure

The UCM procedure uses the following statements:

```

PROC UCM < options > ;
  AUTOREG < options > ;
  BLOCKSEASON options ;
  BY variables ;
  CYCLE < options > ;
  DEPLAG options ;
  ESTIMATE < options > ;
  FORECAST < options > ;
  ID variable options ;
  IRREGULAR < options > ;
  LEVEL < options > ;
  MODEL dependent variable < = regressors > ;
  NLOPTIONS options ;
  OUTLIER options ;
  RANDOMREG regressors < / options > ;
  SEASON options ;
  SLOPE < options > ;
  SPLINEREG regressor < options > ;
  SPLINESEASON options ;

```

The **PROC UCM** and **MODEL** statements are required. In addition, the model must contain at least one component with nonzero disturbance variance.

Functional Summary

The statements and options controlling the UCM procedure are summarized in the following table. Most commonly needed scenarios are listed; see the individual statements for additional details. You can use the **PRINT=** and **PLOT=** options in the individual component statements for printing and plotting the corresponding component forecasts.

Table 31.1 Functional Summary

Description	Statement	Option
Data Set Options		
specify the input data set	PROC UCM	DATA=
write parameter estimates to an output data set	ESTIMATE	OUTEST=
write series and component forecasts to an output data set	FORECAST	OUTFOR=

Table 31.1 *continued*

Description	Statement	Option
Model Specification		
specify the dependent variable and simple predictors	MODEL	
specify predictors with time-varying coefficients	RANDOMREG	
specify a nonlinear predictor	SPLINEREG	
specify the irregular component	IRREGULAR	
specify the random walk trend	LEVEL	
specify the locally linear trend	LEVEL and SLOPE	
specify a cycle component	CYCLE	
specify a dummy seasonal component	SEASON	TYPE=DUMMY
specify a trigonometric seasonal component	SEASON	TYPE=TRIG
drop some harmonics from a trigonometric seasonal component	SEASON	DROPH=
specify a list of harmonics to keep in a trigonometric seasonal component	SEASON	KEEPH=
specify a spline-season component	SPLINESEASON	
specify a block-season component	BLOCKSEASON	
specify an autoreg component	AUTOREG	
specify the lags of the dependent variable	DEPLAG	
Controlling the Likelihood Optimization Process		
request optimization of the profile likelihood	ESTIMATE	PROFILE
request optimization of the usual likelihood	ESTIMATE	NOPROFILE
specify the optimization technique	NLOPTIONS	TECH=
limit the number of iterations	NLOPTIONS	MAXITER=
Outlier Detection		
turn on the search for additive outliers		Default
turn on the search for level shifts	LEVEL	CHECKBREAK
specify the significance level for outlier tests	OUTLIER	ALPHA=
limit the number of outliers	OUTLIER	MAXNUM=
limit the number of outliers to a percentage of the series length	OUTLIER	MAXPCT=
Controlling the Series Span		
exclude some initial observations from analysis during the parameter estimation	ESTIMATE	SKIPFIRST=
exclude some observations at the end from analysis during the parameter estimation	ESTIMATE	BACK=
exclude some initial observations from analysis during forecasting	FORECAST	SKIPFIRST=
exclude some observations at the end from analysis during forecasting	FORECAST	BACK=

turn on a variety of plotting options for the procedure	PROC UCM	PLOTS=
ID		
specify a variable that provides the time index for the series values	ID	

PROC UCM Statement

PROC UCM *< options >* ;

The PROC UCM statement is required. The following options can be used in the PROC UCM statement:

DATA=SAS-data-set

specifies the name of the SAS data set containing the time series. If the DATA= option is not specified in the PROC UCM statement, the most recently created SAS data set is used.

NOPRINT

turns off all the printing for the procedure. The subsequent print options in the procedure are ignored.

PLOTS*< (global-plot-options) >* *< = plot-request < (options) > >*

PLOTS*< (global-plot-options) >* *< = (plot-request < (options) > < ... plot-request < (options) > > >*

controls the plots produced with ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request.

Here are some examples:

```
plots=none
plots=all
plots=residuals(acf loess)
plots(noclm)=(smooth(decomp) residual(panel loess))
```

You must enable ODS Graphics before requesting plots, as shown in the following example. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*).

```
ods graphics on;

proc ucm;
  model y = x;
  irregular;
  level;
run;

proc ucm plots=all;
  model y = x;
  irregular;
  level;
run;
```

The first PROC UCM step does not specify the PLOTS= option, so the default plot that displays the series forecasts in the forecast region is produced. The PLOTS=ALL option in the second PROC UCM step produces all the plots that are appropriate for the specified model.

In addition to the PLOTS= option in the PROC UCM statement, you can request plots by using the PLOT= option in other statements of the UCM procedure. This way of requesting plots provides finer control over the plot production. If you have enabled ODS Graphics but do not specify any specific plot request, then PROC UCM produces the plot of series forecasts in the forecast horizon by default.

Global Plot Options:

The *global-plot-options* apply to all relevant plots generated by the UCM procedure. The following *global-plot-option* is supported:

NOCLM

suppresses the confidence limits in all the component and forecast plots.

Specific Plot Options:

The following list describes the specific plots and their options:

ALL

produces all plots appropriate for the particular analysis.

NONE

suppresses all plots.

FILTER (< *filter-plot-options* >)

produces time series plots of the filtered component estimates. The following *filter-plot-options* are available:

ALL

produces all the filtered component estimate plots appropriate for the particular analysis.

LEVEL

produces a time series plot of the filtered level component estimate, provided the model contains the level component.

SLOPE

produces a time series plot of the filtered slope component estimate, provided the model contains the slope component.

CYCLE

produces time series plots of the filtered cycle component estimates for all cycle components in the model, if there are any.

SEASON

produces time series plots of the filtered season component estimates for all seasonal components in the model, if there are any.

DECOMP

produces time series plots of the filtered estimates of the series decomposition.

RESIDUAL (< *residual-plot-options* >)

produces the residuals plots. The following *residual-plot-options* are available:

ALL

produces all the residual diagnostics plots appropriate for the particular analysis.

ACF

produces the autocorrelation plot of residuals.

CUSUM

produces the plot of cumulative residuals against time.

CUSUMSQ

produces the plot of cumulative squared residuals against time.

HISTOGRAM

produces the histogram of residuals.

LOESS

produces a scatter plot of residuals against time, which has an overlaid loess-fit.

PACF

produces the partial-autocorrelation plot of residuals.

PANEL

produces a summary panel of the residual diagnostics consisting of the following:

- histogram of residuals
- normal quantile plot of residuals
- the residual-autocorrelation-plot
- the residual-partial-autocorrelation-plot

QQ

produces a normal quantile plot of residuals.

RESIDUAL

produces a needle plot of residuals against time.

WN

produces the plot of Ljung-Box white-noise test p -values at different lags (in log scale).

SMOOTH (< *smooth-plot-options* >)

produces time series plots of the smoothed component estimates. The following *smooth-plot-options* are available:

ALL

produces all the smoothed component estimate plots appropriate for the particular analysis.

LEVEL

produces time series plot of the smoothed level component estimate, provided the model contains the level component.

SLOPE

produces time series plot of the smoothed slope component estimate, provided the model contains the slope component.

CYCLE

produces time series plots of the smoothed cycle component estimates for all cycle components in the model, if there are any.

SEASON

produces time series plots of the smoothed season component estimates for all season components in the model, if there are any.

DECOMP

produces time series plots of the smoothed estimates of the series decomposition.

PRINTALL

turns on all the printing options for the procedure. The subsequent NOPRINT options in the procedure are ignored.

AUTOREG Statement

AUTOREG < options > ;

The AUTOREG statement specifies an autoregressive component in the model. An autoregressive component is a special case of cycle that corresponds to the frequency of zero or π . It is modeled separately for easier interpretation. A stochastic equation for an autoregressive component r_t can be written as follows:

$$r_t = \rho r_{t-1} + v_t, \quad v_t \sim i.i.d. N(0, \sigma_v^2)$$

The damping factor ρ can take any value in the interval $(-1, 1)$, including -1 but excluding 1 . If $\rho = 1$, the autoregressive component cannot be distinguished from the random walk level component. If $\rho = -1$, the autoregressive component corresponds to a seasonal component with a season length of 2, or a nonstationary cycle with period 2. If $|\rho| < 1$, then the autoregressive component is stationary. The following example illustrates the AUTOREG statement. This statement includes an autoregressive component in the model. The damping factor ρ and the disturbance variance σ_v^2 are estimated from the data.

autoreg;

NOEST=RHO

NOEST=VARIANCE

NOEST=(RHO VARIANCE)

fixes the values of ρ and σ_v^2 to those specified in the **RHO=** and **VARIANCE=** options.

PLOT=FILTER**PLOT=SMOOTH****PLOT=(< FILTER > < SMOOTH >)**

requests plotting of the filtered or smoothed estimate of the autoreg component.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

requests printing of the filtered or smoothed estimate of the autoreg component.

RHO=valuespecifies an initial value for the damping factor ρ during the parameter estimation process. The value of ρ must be in the interval $(-1, 1)$, including -1 but excluding 1 .**VARIANCE=value**specifies an initial value for the disturbance variance σ_v^2 during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

BLOCKSEASON Statement

BLOCKSEASON *NBLOCKS* = integer *BLOCKSIZE* = integer < options > ;

The **BLOCKSEASON** or **BLOCKSEASONAL** statement is used to specify a seasonal component γ_t that has a special block structure. The seasonal γ_t is called a *block seasonal* of block size m and number of blocks k if its season length, s , can be factored as $s = m * k$ and its seasonal effects have a block form—that is, the first m seasonal effects are all equal to some number τ_1 , the next m effects are all equal to some number τ_2 , and so on.

This type of seasonal structure can be appropriate in some cases; for example, consider a series that is recorded on an hourly basis. Further assume that, in this particular case, the hour-of-the-day effect and the day-of-the-week effect are additive. In this situation the hour-of-the-week seasonality, having a season length of 168, can be modeled as a sum of two components. The hour-of-the-day effect is modeled using a simple seasonal of season length 24, while the day-of-the-week is modeled as a block seasonal component that has the days of the week as blocks. This day-of-the-week block seasonal component has seven blocks, each of size 24.

A block seasonal specification requires, at the minimum, the block size m and the number of blocks in the seasonal k . These are specified using the **BLOCKSIZE=** and **NBLOCKS=** option, respectively. In addition, you might need to specify the position of the first observation of the series by using the **OFFSET=** option if it is not at the beginning of one of the blocks. In the example just considered, this corresponds to a situation where the first series measurement is not at the start of the day. Suppose that the first measurement of the series corresponds to the hour between 6:00 and 7:00 a.m., which is the seventh hour within that day or at the seventh position within that block. This is specified as **OFFSET=7**.

The other options in this statement are very similar to the options in the **SEASON** statement; for example, a block seasonal can also be of one of the two types, **DUMMY** and **TRIG**. There can be more

than one block seasonal component in the model, each specified using a separate BLOCKSEASON statement. No two block seasonals in the model can have the same NBLOCKS= and BLOCKSIZE= specifications. The following example illustrates the use of the BLOCKSEASON statement to specify the additive, hour-of-the-week seasonal model:

```
season length=24 type=trig;
blockseason nblocks=7 blocksize=24;
```

BLOCKSIZE=*integer*

specifies the block size, m . This is a required option in this statement. The block size can be any integer larger than or equal to two. Typical examples of block sizes are 24, corresponding to the hours of the day when a day is being used as a block in hourly data, or 60, corresponding to the minutes in an hour when an hour is being used as a block in data recorded by minutes, etc.

NBLOCKS=*integer*

specifies the number of blocks, k . This is a required option in this statement. The number of blocks can be any integer greater than or equal to two.

NOEST

fixes the value of the disturbance variance parameter to the value specified in the VARIANCE= option.

OFFSET=*integer*

specifies the position of the first measurement within the block, if the first measurement is not at the start of a block. The OFFSET= value must be between one and the block size. The default value is one. The first measurement refers to the start of the estimation span and the forecast span. If these spans differ, their starting measurements must be separated by an integer multiple of the block size.

PLOT=FILTER

PLOT=SMOOTH

PLOT=F_ ANNUAL

PLOT=S_ ANNUAL

PLOT=(< plot request > ... < plot request >)

requests plots of the season component. When you specify only one plot request, you can omit the parentheses around the plot request. You can use the FILTER and SMOOTH options to plot the filtered and smoothed estimates of the season component γ_t . You can use the F_ ANNUAL and S_ ANNUAL options to get the plots of “annual” variation in the filtered and smoothed estimates of γ_t . The annual plots are useful to see the change in the contribution of a particular month over the span of years. Here “month” and “year” are generic terms that change appropriately with the interval type being used to label the observations and the season length. For example, for monthly data with a season length of 12, the usual meaning applies, while for daily data with a season length of 7, the days of the week serve as months and the weeks serve as years. The first period in each block is plotted over the years.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests the printing of the filtered or smoothed estimate of the block seasonal component γ_t .

TYPE=DUMMY | TRIG

specifies the type of the block seasonal component. The default type is DUMMY.

VARIANCE=value

specifies an initial value for the disturbance variance, σ_ω^2 , in the γ_t equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

BY Statement

BY variables ;

A BY statement can be used in the UCM procedure to process a data set in groups of observations defined by the BY variables. The model specified using the MODEL and other component statements is applied to all the groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. The variables are one or more variables in the input data set.

CYCLE Statement

CYCLE < options > ;

The CYCLE statement is used to specify a cycle component, ψ_t , in the model. The stochastic equation governing a cycle component of period p and damping factor ρ is as follows

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos \lambda & \sin \lambda \\ -\sin \lambda & \cos \lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} \nu_t \\ \nu_t^* \end{bmatrix}$$

where ν_t and ν_t^* are independent, zero-mean, Gaussian disturbances with variance σ_ν^2 and $\lambda = 2 * \pi / p$ is the angular frequency of the cycle. Any p strictly greater than two is an admissible value for the period, and the damping factor ρ can be any value in the interval (0, 1), including one but excluding zero. The cycles with frequency zero and π , which correspond to the periods equal to infinity and two, respectively, can be specified using the AUTOREG statement. The values of ρ less than one give rise to a stationary cycle, while $\rho = 1$ gives rise to a nonstationary cycle. As a default, values of ρ , p , and σ_ν^2 are estimated from the data. However, if necessary, you can fix the values of some or all of these parameters.

There can be multiple cycles in a model, each specified using a separate CYCLE statement. The examples that follow illustrate the use of the CYCLE statement.

The following statements request including two cycles in the model. The parameters of each of these cycles are estimated from the data.

```
cycle;
cycle;
```

The following statement requests inclusion of a nonstationary cycle in the model. The cycle period p and the disturbance variance σ_v^2 are estimated from the data.

```
cycle rho=1 noest=rho;
```

In the following statement a nonstationary cycle with a fixed period of 12 is specified. Moreover, a starting value is supplied for σ_v^2 .

```
cycle period=12 rho=1 variance=4 noest=(rho period);
```

NOEST=PERIOD

NOEST=RHO

NOEST=VARIANCE

NOEST=(< RHO > < PERIOD > < VARIANCE >)

fixes the values of the component parameters to those specified in the **RHO=**, **PERIOD=**, and **VARIANCE=** options. This option enables you to fix any combination of parameter values.

PERIOD=value

specifies an initial value for the cycle period during the parameter estimation process. Period value must be strictly greater than 2.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)

requests plotting of the filtered or smoothed estimate of the cycle component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests the printing of a filtered or smoothed estimate of the cycle component ψ_t .

RHO=value

specifies an initial value for the damping factor in this component during the parameter estimation process. Any value in the interval (0, 1), including one but excluding zero, is an acceptable initial value for the damping factor.

VARIANCE=value

specifies an initial value for the disturbance variance parameter, σ_v^2 , to be used during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

DEPLAG Statement

DEPLAG *LAGS* = *order* < *PHI* = *value* ... > < *NOEST* > ;

The DEPLAG statement is used to specify the lags of the dependent variable to be included as predictors in the model. The following examples illustrate the use of DEPLAG statement.

If the dependent series is denoted by y_t , the following statement specifies the inclusion of $\phi_1 y_{t-1} + \phi_2 y_{t-2}$ in the model. The parameters ϕ_1 and ϕ_2 are estimated from the data.

```
deplag lags=2;
```

The following statement requests including $\phi_1 y_{t-1} + \phi_2 y_{t-4} - \phi_1 \phi_2 y_{t-5}$ in the model. The values of ϕ_1 and ϕ_2 are fixed at 0.8 and -1.2.

```
deplag lags=(1) (4) phi=0.8 -1.2 noest;
```

The dependent lag parameters are not constrained to lie in any particular region. In particular, this implies that a UCM that contains only an irregular component and dependent lags, resulting in a traditional autoregressive model, is not constrained to be a stationary model. In the DEPLAG statement, if an initial value is supplied for any one of the parameters, the initial values must also be supplied for all other parameters.

LAGS=*order*

LAGS=(*lag*, ..., *lag*) ... (*lag*, ..., *lag*)

is a required option in this statement. **LAGS**=(l_1, l_2, \dots, l_k) defines a model with specified lags of the dependent variable included as predictors. **LAGS**=*order* is equivalent to **LAGS**=(1, 2, ..., *order*).

A concatenation of parenthesized lists specifies a factored model. For example, **LAGS**=(1)(12) specifies that the lag values, 1, 12, and 13, corresponding to the following polynomial in the backward shift operator, be included in the model

$$(1 - \phi_{1,1}B)(1 - \phi_{2,1}B^{12})$$

Note that, in this case, the coefficient of the thirteenth lag is constrained to be the product of the coefficients of the first and twelfth lags.

NOEST

fixes the values of the parameters to those specified in **PHI**= option.

PHI=*value* ...

lists starting values for the coefficients of the lagged dependent variable. The order of the values listed corresponds with the order of the lags specified in the **LAGS**= option.

ESTIMATE Statement

ESTIMATE < options > ;

The ESTIMATE statement is an optional statement used to control the overall model-fitting environment. Using this statement, you can control the span of observations used to fit the model by using the SKIPFIRST= and BACK= options. This can be useful in model diagnostics. You can request a variety of goodness-of-fit statistics and other model diagnostic information including different residual diagnostic plots. Note that the ESTIMATE statement is not used to control the nonlinear optimization process itself. That is done using the NLOPTIONS statement, where you can control the number of iterations, choose between the different optimization techniques, and so on. You can save the estimated parameters and other related information in a data set by using the OUTEST= option. You can request the optimization of the profile likelihood, the likelihood obtained by concentrating out a disturbance variance, for parameter estimation by using the PROFILE option. The following example illustrates the use of this statement:

```
estimate skipfirst=12 back=24;
```

This statement requests that the initial 12 measurements and the last 24 measurements be excluded during the model-fitting process. The actual observation span used to fit the model is decided as follows: Suppose that n_0 and n_1 are the observation numbers of the first and the last nonmissing values of the response variable, respectively. As a result of SKIPFIRST=12 and BACK=24, the measurements between observation numbers $n_0 + 12$ and $n_1 - 24$ form the estimation span. Of course, the model fitting might not take place if there are insufficient data in the resulting span. The model fitting does not take place if there are regressors in the model that have missing values in the estimation span.

BACK=integer

SKIPLAST=integer

indicates that some ending part of the data needs to be ignored during the parameter estimation. This can be useful when you want to study the forecasting performance of a model on the observed data. BACK=10 results in skipping the last 10 measurements of the response series during the parameter estimation. The default is BACK=0.

EXTRADIFFUSE=k

enables continuation of the diffuse filtering iterations for k additional iterations beyond the first instance where the initialization of the diffuse state would have otherwise taken place. If the specified k is larger than the sample size, the diffuse iterations continue until the end of the sample. Note that one-step-ahead residuals are produced only after the diffuse state is initialized. Delaying the initialization leads to a reduction in the number of one-step-ahead residuals available for computing the residual diagnostic measures. This option is useful when you want to ignore the first few one-step-ahead residuals that often have large variance.

NOPROFILE

requests that the usual likelihood be optimized for parameter estimation. For more information, see the section “Parameter Estimation by Profile Likelihood Optimization” on page 1990.

OUTEST=SAS-data-set

specifies an output data set for the estimated parameters.

In the ESTIMATE statement, the PLOT= option is used to obtain different residual diagnostic plots. The different possibilities are as follows:

PLOT=ACF**PLOT=MODEL****PLOT=LOESS****PLOT=HISTOGRAM****PLOT=PACF****PLOT=PANEL****PLOT=QQ****PLOT=RESIDUAL****PLOT=WN****PLOT=(< plot request > . . . < plot request >)**

requests different residual diagnostic plots. The different options are as follows:

ACF

produces the residual-autocorrelation plot.

CUSUM

produces the plot of cumulative residuals against time.

CUSUMSQ

produces the plot of cumulative squared residuals against time.

MODEL

produces the plot of one-step-ahead forecasts in the estimation span.

HISTOGRAM

produces the histogram of residuals.

LOESS

produces a scatter plot of residuals against time, which has an overlaid loess-fit.

PACF

produces the residual-partial-autocorrelation plot.

PANEL

produces a summary panel of the residual diagnostics consisting of

- histogram of residuals
- normal quantile plot of residuals
- the residual-autocorrelation-plot
- the residual-partial-autocorrelation-plot

QQ

produces a normal quantile plot of residuals.

RESIDUAL

produces a needle plot of residuals against time.

WN

produces a plot of p -values, in log-scale, at different lags for the Ljung-Box portmanteau white noise test statistics.

PRINT=NONE

suppresses all the printed output related to the model fitting, such as the parameter estimates, the goodness-of-fit statistics, and so on.

PROFILE

requests that the profile likelihood, obtained by concentrating out one of the disturbance variances from the likelihood, be optimized for parameter estimation. By default, the profile likelihood is not optimized if any of the disturbance variance parameters is held fixed to a nonzero value. For more information see the section “[Parameter Estimation by Profile Likelihood Optimization](#)” on page 1990.

SKIPFIRST=*integer*

indicates that some early part of the data needs to be ignored during the parameter estimation. This can be useful if there is a reason to believe that the model being estimated is not appropriate for this portion of the data. SKIPFIRST=10 results in skipping the first 10 measurements of the response series during the parameter estimation. The default is SKIPFIRST=0.

FORECAST Statement

FORECAST < *options* > ;

The FORECAST statement is an optional statement that is used to specify the overall forecasting environment for the specified model. It can be used to specify the span of observations, the historical period, to use to compute the forecasts of the future observations. This is done using the SKIPFIRST= and BACK= options. The number of periods to forecast beyond the historical period, and the significance level of the forecast confidence interval, is specified using the LEAD= and ALPHA= options. You can request one-step-ahead series and component forecasts by using the PRINT= option. You can save the series forecasts, and the model-based decomposition of the series, in a data set by using the OUTFOR= option. The following example illustrates the use of this statement:

```
forecast skipfirst=12 back=24 lead=30;
```

This statement requests that the initial 12 and the last 24 response values be excluded during the forecast computations. The forecast horizon, specified using the LEAD= option, is 30 periods; that is, multistep forecasting begins at the end of the historical period and continues for 30 periods. The actual observation span used to compute the multistep forecasting is decided as follows: Suppose that n_0 and n_1 are the observation numbers of the first and the last nonmissing values of the response variable, respectively. As a result of SKIPFIRST=12 and BACK=24, the historical period, or the

forecast span, begins at $n_0 + 12$ and ends at $n_1 - 24$. Multistep forecasts are produced for the next 30 periods—that is, for the observation numbers $n_1 - 23$ to $n_1 + 6$. Of course, the forecast computations can fail if the model has regressor variables that have missing values in the forecast span. If the regressors contain missing values in the forecast horizon—that is, between the observations $n_1 - 23$ and $n_1 + 6$ —the forecast horizon is reduced accordingly.

ALPHA=value

specifies the significance level of the forecast confidence intervals; for example, ALPHA=0.05, which is the default, results in a 95% confidence interval.

BACK=integer**SKIPLAST=integer**

specifies the holdout sample for the evaluation of the forecasting performance of the model. For example, BACK=10 results in treating the last 10 observed values of the response series as unobserved. A post-sample-prediction-analysis table is produced for comparing the predicted values with the actual values in the holdout period. The default is BACK=0.

EXTRADIFFUSE=k

enables continuation of the diffuse filtering iterations for k additional iterations beyond the first instance where the initialization of the diffuse state would have otherwise taken place. If the specified k is larger than the sample size, the diffuse iterations continue until the end of the sample. Note that one-step-ahead forecasts are produced only after the diffuse state is initialized. Delaying the initialization leads to reduction in the number of one-step-ahead forecasts. This option is useful when you want to ignore the first few one-step-ahead forecasts that often have large variance.

LEAD=integer

specifies the number of periods to forecast beyond the historical period defined by the SKIPFIRST= and BACK= options; for example, LEAD=10 results in the forecasting of 10 future values of the response series. The default is LEAD=12.

OUTFOR=SAS-data-set

specifies an output data set for the forecasts. The output data set contains the ID variable (if specified), the response and predictor series, the one-step-ahead and out-of-sample response series forecasts, the forecast confidence intervals, the smoothed values of the response series, and the smoothed forecasts produced as a result of the model-based decomposition of the series.

PLOT=DECOMP**PLOT=DECOMPVAR****PLOT=FDECOMP****PLOT=FDECOMPVAR****PLOT=FORECASTS****PLOT=TREND****PLOT=(< plot request > ... < plot request >)**

requests forecast and model decomposition plots. The FORECASTS option provides the plot of the series forecasts, the TREND and DECOMP options provide the plots of the smoothed trend and other decompositions, the DECOMPVAR option can be used to plot the variance of

these components, and the FDECOMP and FDECOMPVAR options provide the same plots for the filtered decomposition estimates and their variances.

PRINT=DECOMP

PRINT=FDECOMP

PRINT=FORECASTS

PRINT=NONE

PRINT=(< print request > ... < print request >)

controls the printing of the series forecasts and the printing of smoothed model decomposition estimates. By default, the series forecasts are printed only for the forecast horizon specified by the LEAD= option; that is, the one-step-ahead predicted values are not printed. You can request forecasts for the entire forecast span by specifying the PRINT=FORECASTS option. Using PRINT=DECOMP, you can get smoothed estimates of the following effects: trend, trend plus regression, trend plus regression plus cycle, and sum of all components except the irregular. If some of these effects are absent in the model, then they are ignored. Similarly you can get filtered estimates of these effects by using PRINT=FDECOMP. You can use PRINT=NONE to suppress the printing of all the forecast output.

SKIPFIRST=*integer*

indicates that some early part of the data needs to be ignored during the forecasting calculations. This can be useful if there is a reason to believe that the model being used for forecasting is not appropriate for this portion of the data. SKIPFIRST=10 results in skipping the first 10 measurements of the response series during the forecast calculations. The default is SKIPFIRST=0.

ID Statement

ID *variable* INTERVAL=*value* < ALIGN=*value* > ;

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date, time, or datetime values. In addition, the ID statement specifies the frequency associated with the time series. The ID statement options also specify how the observations are aligned to form the time series. If the ID statement is specified, the INTERVAL= option must also be specified. If the ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID. The values of the ID variable are extrapolated for the forecast observations based on the values of the INTERVAL= option.

ALIGN=*value*

controls the alignment of SAS dates used to identify output observations. The ALIGN= option has the following possible values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. The default is BEGINNING. The ALIGN= option is used to align the ID variable with the beginning, middle, or end of the time ID interval specified by the INTERVAL= option.

INTERVAL=*value*

specifies the time interval between observations. This option is required in the ID statement. INTERVAL=*value* is used in conjunction with the ID variable to check that the input data are

in order and have no gaps. The INTERVAL= option is also used to extrapolate the ID values past the end of the input data. For a complete discussion of the intervals supported, please see Chapter 4, “Date Intervals, Formats, and Functions.”

IRREGULAR Statement

IRREGULAR < options > ;

The IRREGULAR statement includes an irregular component in the model. There can be at most one IRREGULAR statement in the model specification. The irregular component corresponds to the overall random error ϵ_t in the model. By default the irregular component is modeled as white noise—that is, as a sequence of independent, identically distributed, zero-mean, Gaussian random variables. However, you can also model it as an autoregressive moving average (ARMA) process. The options for specifying an ARMA model for the irregular component are given in a separate subsection: “ARMA Specification” on page 1961.

The options in this statement enable you to specify the model for the irregular component and to output its estimates. Two examples of the IRREGULAR statement are given next. In the first example the statement is in its simplest form, resulting in the inclusion of an irregular component that is white noise with unknown variance:

```
irregular;
```

The following statement provides a starting value for the white noise variance σ_ϵ^2 to be used in the nonlinear parameter estimation process. It also requests the printing of smoothed estimates of ϵ_t . The smoothed irregulars are useful in model diagnostics.

```
irregular variance=4 print=smooth;
```

NOEST

fixes the value of σ_ϵ^2 to the value specified in the VARIANCE= option. Also see the NOEST= option in the subsection “ARMA Specification” on page 1961.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)

requests plotting of the filtered or smoothed estimate of the irregular component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests printing of the filtered or smoothed estimate of the irregular component.

VARIANCE=value

specifies an initial value for σ_ϵ^2 during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

ARMA Specification

This section details the options for specifying an ARMA model for the irregular component. The specification of ARMA models requires some notation, which is explained first.

Let B denote the backshift operator—that is, for any sequence ϵ_t , $B\epsilon_t = \epsilon_{t-1}$. The higher powers of B represent larger shifts (for example, $B^3\epsilon_t = \epsilon_{t-3}$). A random sequence ϵ_t follows a zero-mean ARMA(p,q) \times (P,Q) $_s$ model with nonseasonal autoregressive order p , seasonal autoregressive order P , nonseasonal moving average order q , and seasonal moving average order Q , if it satisfies the following difference equation specified in terms of the polynomials in the backshift operator where a_t is a white noise sequence and s is the season length:

$$\phi(B)\Phi(B^s)\epsilon_t = \theta(B)\Theta(B^s)a_t$$

The polynomials ϕ , Φ , θ , and Θ are of orders p , P , q , and Q , respectively, which can be any nonnegative integers. The season length s must be a positive integer. For example, ϵ_t satisfies an ARMA(1,1) model (that is, $p = 1$, $q = 1$, $P = 0$, and $Q = 0$) if

$$\epsilon_t = \phi_1\epsilon_{t-1} + a_t - \theta_1a_{t-1}$$

for some coefficients ϕ_1 and θ_1 and a white noise sequence a_t . Similarly ϵ_t satisfies an ARMA(1,1) \times (1,1) $_2$ model if

$$\epsilon_t = \phi_1\epsilon_{t-1} + \Phi_1\epsilon_{t-2} - \phi_1\Phi_1\epsilon_{t-3} + a_t - \theta_1a_{t-1} - \Theta_1a_{t-2} + \theta_1\Theta_1a_{t-3}$$

for some coefficients ϕ_1 , Φ_1 , θ_1 , and Θ_1 and a white noise sequence a_t . The ARMA process is stationary and invertible if the defining polynomials ϕ , Φ , θ , and Θ have all their roots outside the unit circle—that is, their absolute values are strictly larger than 1.0. It is assumed that the ARMA model specified for the irregular component is stationary and invertible—that is, the coefficients of the polynomials ϕ , Φ , θ , and Θ are constrained so that the stationarity and invertibility conditions are satisfied. The unknown coefficients of these polynomials become part of the model parameter vector that is estimated using the data.

The notation for a closely related class of models, autoregressive integrated moving average (ARIMA) models, is also given here. A random sequence y_t is said to follow an ARIMA(p,d,q) \times (P,D,Q) $_s$ model if, for some nonnegative integers d and D , the differenced series $\epsilon_t = (1 - B)^d(1 - B^s)^D y_t$ follows an ARMA(p,q) \times (P,Q) $_s$ model. The integers d and D are called nonseasonal and seasonal differencing orders, respectively. You can specify ARIMA models by using the `DEPLAG` statement for specifying the differencing orders and by using the `IRREGULAR` statement for the ARMA specification. See [Example 31.8](#) for an example of ARIMA(0,1,1) \times (0,1,1) $_2$ model specification. Brockwell and Davis (1991) can be consulted for additional information about ARIMA models.

You can use options of the `IRREGULAR` statement to specify the desired ARMA model and to request printed and graphical output. A few examples of the `IRREGULAR` statement are given next.

The following statement specifies an irregular component that is modeled as an ARMA(1,1) process. It also requests plotting its smoothed estimate.

```
irregular p=1 q=1 plot=smooth;
```

The following statement specifies an ARMA(1,1)×(1,1)₁₂ model. It also fixes the coefficient of the first-order seasonal moving average polynomial to 0.1. The other coefficients and the white noise variance are estimated using the data.

```
irregular p=1 sp=1 q=1 sq=1 s=12 sma=0.1 noest=(sma);
```

AR= $\phi_1 \phi_2 \dots \phi_p$

lists the starting values of the coefficients of the nonseasonal autoregressive polynomial

$$\phi(B) = 1 - \phi_1 B - \dots - \phi_p B^p$$

where the order p is specified in the **P=** option. The coefficients ϕ_i must define a stationary autoregressive polynomial.

MA= $\theta_1 \theta_2 \dots \theta_q$

lists the starting values of the coefficients of the nonseasonal moving average polynomial

$$\theta(B) = 1 - \theta_1 B - \dots - \theta_q B^q$$

where the order q is specified in the **Q=** option. The coefficients θ_i must define an invertible moving average polynomial.

NOEST=(<**VARIANCE**> <**AR**> <**SAR**> <**MA**> <**SMA**>)

fixes the values of the ARMA parameters and the value of the white noise variance to those specified in the **AR=**, **SAR=**, **MA=**, **SMA=**, or **VARIANCE=** options.

P=integer

specifies the order of the nonseasonal autoregressive polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1, 2, or 3.

Q=integer

specifies the order of the nonseasonal moving average polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1, 2, or 3.

S=integer

specifies the season length used during the specification of the seasonal autoregressive or seasonal moving average polynomial. The season length can be any positive integer; for example, $S=4$ might be an appropriate value for a quarterly series. The default value is $S=1$.

SAR= $\Phi_1 \Phi_2 \dots \Phi_P$

lists the starting values of the coefficients of the seasonal autoregressive polynomial

$$\Phi(B^s) = 1 - \Phi_1 B^s - \dots - \Phi_P B^{sP}$$

where the order P is specified in the **SP=** option and the season length s is specified in the **S=** option. The coefficients Φ_i must define a stationary autoregressive polynomial.

SMA= $\Theta_1 \Theta_2 \dots \Theta_Q$

lists the starting values of the coefficients of the seasonal moving average polynomial

$$\Theta(B^s) = 1 - \Theta_1 B^s - \dots - \Theta_Q B^{sQ}$$

where the order Q is specified in the **SQ**= option and the season length s is specified in the **S**= option. The coefficients Θ_i must define an invertible moving average polynomial.

SP=integer

specifies the order of the seasonal autoregressive polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1 or 2.

SQ=integer

specifies the order of the seasonal moving average polynomial. The order can be any non-negative integer; the default value is 0. In practice the order is a small integer such as 1 or 2.

LEVEL Statement

LEVEL < options > ;

The **LEVEL** statement is used to include a level component in the model. The level component, either by itself or together with a slope component (see the **SLOPE** statement), forms the trend component, μ_t , of the model. If the slope component is absent, the resulting trend is a random walk (RW) specified by the following equations:

$$\mu_t = \mu_{t-1} + \eta_t, \quad \eta_t \sim i.i.d. N(0, \sigma_\eta^2)$$

If the slope component is present, signified by the presence of a **SLOPE** statement, a locally linear trend (LLT) is obtained. The equations of LLT are as follows:

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim i.i.d. N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim i.i.d. N(0, \sigma_\xi^2) \end{aligned}$$

In either case, the options in the **LEVEL** statement are used to specify the value of σ_η^2 and to request forecasts of μ_t . The **SLOPE** statement is used for similar purposes in the case of slope β_t . The following examples illustrate the use of the **LEVEL** statement. Assuming that a **SLOPE** statement is not added subsequently, a simple random walk trend is specified by the following statement:

level;

The following statements specify a locally linear trend with value of σ_η^2 fixed at 4. It also requests printing of filtered values of μ_t . The value of σ_ξ^2 , the disturbance variance in the slope equation, is estimated from the data.

```
level variance=4 noest print=filter;
slope;
```

CHECKBREAK

turns on the checking of breaks in the level component.

NOEST

fixes the value of σ_{η}^2 to the value specified in the **VARIANCE=** option.

PLOT=FILTER**PLOT=SMOOTH****PLOT=(< FILTER > < SMOOTH >)**

requests plotting of the filtered or smoothed estimate of the level component.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

requests printing of the filtered or smoothed estimate of the level component.

VARIANCE=value

specifies an initial value for σ_{η}^2 , the disturbance variance in the μ_t equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

MODEL Statement

```
MODEL dependent < = regressors > ;
```

The MODEL statement specifies the response variable and, optionally, the predictor or regressor variables for the UCM model. This is a required statement in the UCM procedure. The predictors specified in the MODEL statement are assumed to have a linear and time-invariant relationship with the response. The predictors that have time-varying regression coefficients are specified separately in the **RANDOMREG** statement. Similarly, the predictors that have a nonlinear effect on the response variable are specified separately in the **SPLINEREG** statement. Only one MODEL statement can be specified.

NLOPTIONS Statement

```
NLOPTIONS < options > ;
```

PROC UCM uses the nonlinear optimization (NLO) subsystem to perform the nonlinear optimization of the likelihood function during the estimation of model parameters. You can use the NLOPTIONS statement to control different aspects of this optimization process. For most problems the default

settings of the optimization process are adequate. However, in some cases it might be useful to change the optimization technique or to change the maximum number of iterations. This can be done by using the TECH= and MAXITER= options in the NLOPTIONS statement as follows:

```
nloptions tech=dbldog maxiter=200;
```

This sets the maximum number of iterations to 200 and changes the optimization technique to DBLDOG rather than the default technique, TRUREG, used in PROC UCM. A discussion of the full range of options that can be used with the NLOPTIONS statement is given in Chapter 6, “[Nonlinear Optimization Methods](#).” In PROC UCM all these options are available except the options related to the printing of the optimization history. In this version of PROC UCM all the printed output from the NLO subsystem is suppressed.

OUTLIER Statement

OUTLIER < options > ;

The OUTLIER statement enables you to control the reporting of the additive outliers (AO) and level shifts (LS) in the response series. The AOs are searched by default. You can turn on the search for LSs by using the [CHECKBREAK](#) option in the LEVEL statement.

ALPHA=*significance-level*

specifies the significance level for reporting the outliers. The default is 0.05.

MAXNUM=*number*

limits the number of outliers to search. The default is MAXNUM=5.

MAXPCT=*number*

is similar to the MAXNUM= option. In the MAXPCT= option you can limit the number of outliers to search for according to a percentage of the series length. The default is MAXPCT=1. When both of these options are specified, the minimum of the two search numbers is used.

PRINT=SHORT | DETAIL

enables you to control the printed output of the outlier search. The PRINT=SHORT option, which is the default, produces an outlier summary table containing the most significant outliers, either AO or LS, discovered in the outlier search. The PRINT=DETAIL option produces, in addition to the outlier summary table, separate tables containing the AO and LS structural break chi-square statistics computed at each time point in the estimation span.

RANDOMREG Statement

RANDOMREG *regressors* </ options > ;

The RANDOMREG statement is used to specify regressors with time-varying regression coefficients. Each regression coefficient—say, β_t —is assumed to evolve as a random walk:

$$\beta_t = \beta_{t-1} + \eta_t, \quad \eta_t \sim i.i.d. N(0, \sigma^2)$$

Of course, if the random walk disturbance variance σ^2 is zero, then the regression coefficient is not time varying, and it reduces to the standard regression setting. There can be multiple RANDOMREG statements, and each statement can contain one or more regressors. The regressors in a given RANDOMREG statement form a group that is assumed to share the same disturbance variance parameter. The random walks associated with different regressors are assumed to be independent. For an example of using this statement see [Example 31.4](#). See the section “Reporting Parameter Estimates for Random Regressors” on page 1986 for additional information about the way parameter estimates are reported for this type of regressors.

NOEST

fixes the value of σ^2 to the value specified in the **VARIANCE=** option.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)

requests plotting of filtered or smoothed estimate of the time-varying regression coefficient.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests printing of the filtered or smoothed estimate of the time-varying regression coefficient.

VARIANCE=*value*

specifies an initial value for σ^2 during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SEASON Statement

SEASON *LENGTH = integer* < options > ;

The SEASON or SEASONAL statement is used to specify a seasonal component, γ_t , in the model. A seasonal component can be one of the two types, DUMMY or TRIG. A DUMMY seasonal with season length s satisfies the following stochastic equation:

$$\sum_{i=0}^{s-1} \gamma_{t-i} = \omega_t, \quad \omega_t \sim i.i.d. N(0, \sigma_\omega^2)$$

The equations for a TRIG (short for trigonometric) seasonal component are as follows

$$\gamma_t = \sum_{j=1}^{[s/2]} \gamma_{j,t}$$

where $[s/2]$ equals $s/2$ if s is even and $(s-1)/2$ if it is odd. The sinusoids, also called *harmonics*, $\gamma_{j,t}$ have frequencies $\lambda_j = 2\pi j/s$ and are specified by the matrix equation

$$\begin{bmatrix} \gamma_{j,t} \\ \gamma_{j,t}^* \end{bmatrix} = \begin{bmatrix} \cos \lambda_j & \sin \lambda_j \\ -\sin \lambda_j & \cos \lambda_j \end{bmatrix} \begin{bmatrix} \gamma_{j,t-1} \\ \gamma_{j,t-1}^* \end{bmatrix} + \begin{bmatrix} \omega_{j,t} \\ \omega_{j,t}^* \end{bmatrix}$$

where the disturbances $\omega_{j,t}$ and $\omega_{j,t}^*$ are assumed to be independent and, for fixed j , $\omega_{j,t}$ and $\omega_{j,t}^* \sim N(0, \sigma_\omega^2)$. If s is even, then the equation for $\gamma_{s/2,t}^*$ is not needed and $\gamma_{s/2,t}$ is given by

$$\gamma_{s/2,t} = -\gamma_{s/2,t-1} + \omega_{s/2,t}$$

In the TRIG seasonal case, the option **KEEPH=** or **DROPH=** can be used to obtain *subset trigonometric* seasonals that contain only a subset of the full set of harmonics $\gamma_{j,t}$, $j = 1, 2, \dots, [s/2]$. This is particularly useful when the season length s is large and the seasonal pattern is relatively smooth.

Note that whether the seasonal type is DUMMY or TRIG, there is only one parameter, the disturbance variance σ_ω^2 , in the seasonal model.

There can be more than one seasonal component in the model, necessarily with different season lengths if the seasons are full. You can have multiple *subset* season components with the same season length, if you need to use separate disturbance variances for different sets of harmonics. Each seasonal component is specified using a separate SEASON statement. A model with multiple seasonal components can easily become quite complex and might need a large amount of data and computing resources for its estimation and forecasting. The examples that follow illustrate the use of SEASON statement.

The following statement specifies a DUMMY type (default) seasonal component with a season length of four, corresponding to the quarterly seasonality. The disturbance variance σ_ω^2 is estimated from the data.

```
season length=4;
```

The following statement specifies a trigonometric seasonal with monthly seasonality. It also provides a starting value for σ_ω^2 .

```
season length=12 type=trig variance=4;
```

DROPHARMONICS|DROPH=number-list | n TO m BY p

enables you to drop some harmonics $\gamma_{j,t}$ from the full set of harmonics used to obtain a trigonometric seasonal. The drop list can include any integer between 1 and $[s/2]$, s being the season length. For example, the following specification results in a specification of a trigonometric seasonal with a season length 12 that consists of only the first four harmonics $\gamma_{j,t}$, $j = 1, 2, 3, 4$:

```
season length=12 type=trig DROPH=5 6;
```

The last two *high* frequency harmonics are dropped. The **DROPH=** option cannot be used with the **KEEPH=** option.

KEEPHARMONICS|KEEPH=number-list | n TO m BY p

enables you to keep only the harmonics $\gamma_{j,t}$ listed in the option to obtain a trigonometric seasonal. The keep list can include any integer between 1 and $[s/2]$, s being the season length. For example, the following specification results in a specification of a trigonometric seasonal with a season length of 12 that consists of all the six harmonics $\gamma_{j,t}$, $j = 1, \dots, 6$:

```
season length=12 type=trig KEEPH=1 to 3;
season length=12 type=trig KEEPH=4 to 6;
```

However, these six harmonics are grouped into two groups, each having its own disturbance variance parameter. The **DROPH=** option cannot be used with the **KEEPH=** option.

LENGTH=integer

specifies the season length, s . This is a required option in this statement. The season length can be any integer greater than or equal to 2. Typical examples of season lengths are 12, corresponding to the monthly seasonality, or 4, corresponding to the quarterly seasonality.

NOEST

fixes the value of the disturbance variance parameter to the value specified in the **VARIANCE=** option.

PLOT=FILTER

PLOT=SMOOTH

PLOT=F_ ANNUAL

PLOT=S_ ANNUAL

PLOT=(<plot request> ... <plot request>)

requests plots of the season component. When you specify only one plot request, you can omit the parentheses around the plot request. You can use the **FILTER** and **SMOOTH** options to plot the filtered and smoothed estimates of the season component γ_t . You can use the **F_ ANNUAL** and **S_ ANNUAL** options to get the plots of “annual” variation in the filtered and smoothed estimates of γ_t . The annual plots are useful to see the change in the contribution of a particular month over the span of years. Here “month” and “year” are generic terms that change appropriately with the interval type being used to label the observations and the season length. For example, for monthly data with a season length of 12, the usual meaning applies, while for daily data with a season length of 7, the days of the week serve as months and the weeks serve as years.

PRINT=HARMONICS

requests printing of the summary of harmonics present in the seasonal component. This option is valid only for the trigonometric seasonal component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< print request > ... < print request >)

requests printing of the filtered or smoothed estimate of the seasonal component γ_t .

TYPE=DUMMY | TRIG

specifies the type of the seasonal component. The default type is DUMMY.

VARIANCE=value

specifies an initial value for the disturbance variance, σ_ω^2 , in the γ_t equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SLOPE Statement

SLOPE < options > ;

The SLOPE statement is used to include a slope component in the model. The slope component cannot be used without the level component (see the **LEVEL** statement). The level and slope specifications jointly define the trend component of the model. A SLOPE statement without the accompanying LEVEL statement is ignored. The equations of the trend, defined jointly by the level μ_t and slope β_t , are as follows:

$$\begin{aligned}\mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim i.i.d. N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim i.i.d. N(0, \sigma_\xi^2)\end{aligned}$$

The SLOPE statement is used to specify the value of the disturbance variance, σ_ξ^2 , in the slope equation, and to request forecasts of β_t . The following examples illustrate this statement:

```
level;
slope;
```

The preceding statements fit a model with a locally linear trend. The disturbance variances σ_η^2 and σ_ξ^2 are estimated from the data. You can request a locally linear trend with fixed slope by using the following statements:

```
level;
slope variance=0 noest;
```

NOEST

fixes the value of the disturbance variance, σ_ξ^2 , to the value specified in the **VARIANCE=** option.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)

requests plotting of the filtered or smoothed estimate of the slope component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests printing of the filtered or smoothed estimate of the slope component β_t .

VARIANCE=value

specifies an initial value for the disturbance variance, σ_ξ^2 , in the β_t equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SPLINEREG Statement

SPLINEREG regressor < options > ;

The SPLINEREG statement is used to specify a regressor that has a nonlinear relationship with the dependent series that can be approximated by a given B-spline. If the specified spline has degree d and is based on n internal knots, then it is known that it can be written as a linear combination of $(n + d + 1)$ regressors that are derived from the original regressor. The span of these $(n + d + 1)$ derived regressors includes constant; therefore, to avoid multicollinearity with the level component, one of these regressors is dropped. Specifying the SPLINEREG statement is equivalent to specifying a RANDOMREG statement with these derived regressors. There can be multiple SPLINEREG statements. You must specify at least one interior knot, either using the NKNOTS= option or the KNOTS= option. For additional information about splines, see Chapter 91, “The TRANSREG Procedure” (*SAS/STAT User’s Guide*). For an example of using this statement, see [Example 31.6](#). See the section “[Reporting Parameter Estimates for Random Regressors](#)” on page 1986 for additional information about the way parameter estimates are reported for this type of regressors.

DEGREE=integer

specifies the degree of the spline. It can be any integer larger than or equal to zero. The default value is 3. The polynomial degree should be a small integer, usually 0, 1, 2, or 3. Larger values are rarely useful. If you have any doubt as to what degree to specify, use the default.

KNOTS=number-list | n TO m BY p

specifies the interior knots or break points. The values in the knot list must be nondecreasing and must lie between the minimum and the maximum of the spline regressor values in the input data set. The first time you specify a value in the knot list, it indicates a discontinuity in the n th (from DEGREE= n) derivative of the transformation function at the value of the knot. The second mention of a value indicates a discontinuity in the $(n - 1)$ th derivative of the transformation function at the value of the knot. Knots can be repeated any number of times for decreasing smoothness at the break points, but the values in the knot list can never decrease.

You cannot use the KNOTS= option with the NKNOTS= option. You should keep the number of knots small.

NKNOTS=*m*

creates *m* knots, the first at the $100/(m + 1)$ percentile, the second at the $200/(m + 1)$ percentile, and so on. Knots are always placed at data values; there is no interpolation. For example, if NKNOTS=3, knots are placed at the 25th percentile, the median, and the 75th percentile. The value specified for the NKNOTS= option must be ≥ 1 . You cannot use the NKNOTS= option with the KNOTS= option.

NOTE: Specifying knots by using the NKNOTS= option can result in different sets of knots in the estimation and forecast stages if the distributions of regressor values in the estimation and forecast spans differ. The estimation span is based on the BACK= and SKIPFIRST= options in the ESTIMATE statement, and the forecast span is based on the BACK= and SKIPFIRST= options in the FORECAST statement.

NOEST

fixes the value of the regression coefficient random walk disturbance variance to the value specified in the VARIANCE= option.

PLOT=FILTER**PLOT=SMOOTH****PLOT=(< FILTER > < SMOOTH >)**

requests plotting of filtered or smoothed estimate of the time-varying regression coefficient.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

requests printing of filtered or smoothed estimate of the time-varying regression coefficient.

VARIANCE=*value*

specifies an initial value for the regression coefficient random walk disturbance variance during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SPLINESEASON Statement

SPLINESEASON *LENGTH* = *integer* **KNOTS** = *integer*₁ *integer*₂ ... < options > ;

The SPLINESEASON statement is used to specify a seasonal pattern that is to be approximated by a given B-spline. If the specified spline has degree *d* and is based on *n* internal knots, then it can be written as a linear combination of (*n* + *d*) regressors that are derived from the seasonal dummy regressors. The SPLINESEASON specification is equivalent to specifying a RANDOMREG specification with these derived regressors. Such approximation is useful only if the season length is relatively large, at least larger than (*n* + *d*). For additional information about splines, see Chapter 91, “The TRANSREG Procedure” (*SAS/STAT User’s Guide*). For an example of using this statement, see Example 31.3.

DEGREE=integer

specifies the degree of the spline. It can be any integer greater than or equal to zero. The default value is 3.

KNOTS=integer₁ integer₂ ...

lists the *internal* knots. This list of values must be a nondecreasing sequence of integers within the range of 2 to $(s - 1)$, where s is the season length specified in the **LENGTH=** option. This is a required option in this statement.

LENGTH=integer

specifies the season length, s . This is a required option in this statement. The length can be any integer greater than or equal to three.

NOEST

fixes the value of the regression coefficient random walk disturbance variance to the value specified in the **VARIANCE=** option.

OFFSET=integer

specifies the position of the first measurement within the season, if the first measurement is not at the start of the season. The **OFFSET=** value must be between one and the season length. The default value is one. The first measurement refers to the start of the estimation span and the forecast span. If these spans differ, their starting measurements must be separated by an integer multiple of the season length.

PLOT=FILTER**PLOT=SMOOTH****PLOT=(< FILTER > < SMOOTH >)**

requests plots of the season component. When you specify only one plot request, you can omit the parentheses around the plot request. You can use the **FILTER** and **SMOOTH** options to plot the filtered and smoothed estimates of the season component.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

requests the printing of the filtered or smoothed estimate of the spline season component.

RKNOTS=(knot, ..., knot) ... (knot, ..., knot)

specifies a grouping of knots such that the knots within the same group have identical seasonal values. The knots specified in this option must already be present in the list specified by the **KNOTS=** option. The knot groups must be non-overlapping and without any repeated knots.

Experimental

VARIANCE=value

specifies an initial value for the regression coefficient random walk disturbance variance during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

Details: UCM Procedure

An Introduction to Unobserved Component Models

A UCM decomposes the response series into components such as trend, seasons, cycles, and the regression effects due to predictor series. The following model shows a possible scenario:

$$y_t = \mu_t + \gamma_t + \psi_t + \sum_{j=1}^m \beta_j x_{jt} + \epsilon_t$$

$$\epsilon_t \sim i.i.d. N(0, \sigma_\epsilon^2)$$

The terms μ_t , γ_t , and ψ_t represent the trend, seasonal, and cyclical components, respectively. In fact the model can contain multiple seasons and cycles, and the seasons can be of different types. For simplicity of discussion the preceding model contains only one of each of these components. The regression term, $\sum_{j=1}^m \beta_j x_{jt}$, includes contribution of regression variables with *fixed* regression coefficients. A model can also contain regression variables that have *time varying* regression coefficients or that have a nonlinear relationship with the dependent series (see “[Incorporating Predictors of Different Kinds](#)” on page 1985). The disturbance term ϵ_t , also called the *irregular* component, is usually assumed to be Gaussian white noise. In some cases it is useful to model the irregular component as a stationary ARMA process. See the section “[Modeling the Irregular Component](#)” on page 1977 for additional information.

By controlling the presence or absence of various terms and by choosing the proper flavor of the included terms, the UCMs can generate a rich variety of time series patterns. A UCM can be applied to variables after transforming them by transforms such as *log* and *difference*.

The components μ_t , γ_t , and ψ_t model structurally different aspects of the time series. For example, the trend μ_t models the natural tendency of the series in the absence of any other perturbing effects such as seasonality, cyclical components, and the effects of exogenous variables, while the seasonal component γ_t models the correction to the level due to the seasonal effects. These components are assumed to be statistically independent of each other and independent of the irregular component. All of the component models can be thought of as stochastic generalizations of the relevant deterministic patterns in time. This way the deterministic cases emerge as special cases of the stochastic models. The different models available for these unobserved components are discussed next.

Modeling the Trend

As mentioned earlier, the trend in a series can be loosely defined as the natural tendency of the series in the absence of any other perturbing effects. The UCM procedure offers two ways to model the trend component μ_t . The first model, called the random walk (RW) model, implies that the trend remains roughly constant throughout the life of the series without any persistent upward or downward drift. In the second model the trend is modeled as a locally linear time trend (LLT). The

RW model can be described as

$$\mu_t = \mu_{t-1} + \eta_t, \quad \eta_t \sim i.i.d. N(0, \sigma_\eta^2)$$

Note that if $\sigma_\eta^2 = 0$, then the model becomes $\mu_t = \text{constant}$. In the LLT model the trend is locally linear, consisting of both the *level* and *slope*. The LLT model is

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim i.i.d. N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim i.i.d. N(0, \sigma_\xi^2) \end{aligned}$$

The disturbances η_t and ξ_t are assumed to be independent. There are some interesting special cases of this model obtained by setting one or both of the disturbance variances σ_η^2 and σ_ξ^2 equal to zero. If σ_ξ^2 is set equal to zero, then you get a linear trend model with fixed slope. If σ_η^2 is set to zero, then the resulting model usually has a smoother trend. If both the variances are set to zero, then the resulting model is the deterministic linear time trend: $\mu_t = \mu_0 + \beta_0 t$.

You can incorporate these trend patterns in your model by using the **LEVEL** and **SLOPE** statements.

Modeling a Cycle

A deterministic cycle ψ_t with frequency λ , $0 < \lambda < \pi$, can be written as

$$\psi_t = \alpha \cos(\lambda t) + \beta \sin(\lambda t)$$

If the argument t is measured on a continuous scale, then ψ_t is a periodic function with period $2\pi/\lambda$, amplitude $\gamma = (\alpha^2 + \beta^2)^{1/2}$, and phase $\phi = \tan^{-1}(\beta/\alpha)$. Equivalently, the cycle can be written in terms of the amplitude and phase as

$$\psi_t = \gamma \cos(\lambda t - \phi)$$

Note that when ψ_t is measured only at the integer values, it is not exactly periodic, unless $\lambda = (2\pi j)/k$ for some integers j and k . The cycles in their pure form are not used very often in practice. However, they are very useful as building blocks for more complex periodic patterns. It is well known that the periodic pattern of any complexity can be written as a sum of pure cycles of different frequencies and amplitudes. In time series situations it is useful to generalize this simple cyclical pattern to a stochastic cycle that has a fixed period but time-varying amplitude and phase. The stochastic cycle considered here is motivated by the following recursive formula for computing ψ_t :

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \begin{bmatrix} \cos \lambda & \sin \lambda \\ -\sin \lambda & \cos \lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix}$$

starting with $\psi_0 = \alpha$ and $\psi_0^* = \beta$. Note that ψ_t and ψ_t^* satisfy the relation

$$\psi_t^2 + \psi_t^{*2} = \alpha^2 + \beta^2 \quad \text{for all } t$$

A stochastic generalization of the cycle ψ_t can be obtained by adding random noise to this recursion and by introducing a damping factor, ρ , for additional modeling flexibility. This model can be described as follows

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos \lambda & \sin \lambda \\ -\sin \lambda & \cos \lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} v_t \\ v_t^* \end{bmatrix}$$

where $0 \leq \rho \leq 1$, and the disturbances v_t and v_t^* are independent $N(0, \sigma_v^2)$ variables. The resulting stochastic cycle has a fixed period but time-varying amplitude and phase. The stationarity properties of the random sequence ψ_t depend on the damping factor ρ . If $\rho < 1$, ψ_t has a stationary distribution with mean zero and variance $\sigma_v^2/(1 - \rho^2)$. If $\rho = 1$, ψ_t is nonstationary.

You can incorporate a cycle in a UCM by specifying a **CYCLE** statement. You can include multiple cycles in the model by using separate **CYCLE** statements for each included cycle.

As mentioned before, the cycles are very useful as building blocks for constructing more complex periodic patterns. Periodic patterns of almost any complexity can be created by superimposing cycles of different periods and amplitudes. In particular, the seasonal patterns, general periodic patterns with integer periods, can be constructed as sums of cycles. This important topic of modeling the seasonal components is considered next.

Modeling Seasons

The seasonal fluctuations are a common source of variation in time series data. These fluctuations arise because of the regular changes in seasons or some other periodic events. The seasonal effects are regarded as corrections to the general trend of the series due to the seasonal variations, and these effects sum to zero when summed over the full season cycle. Therefore the seasonal component γ_t is modeled as a stochastic periodic pattern of an integer period s such that the sum $\sum_{i=0}^{s-1} \gamma_{t-i}$ is always zero in the mean. The period s is called the season length. Two different models for the seasonal component are considered here. The first model is called the *dummy* variable form of the seasonal component. It is described by the equation

$$\sum_{i=0}^{s-1} \gamma_{t-i} = \omega_t, \quad \omega_t \sim i.i.d. N(0, \sigma_\omega^2)$$

The other model is called the *trigonometric* form of the seasonal component. In this case γ_t is modeled as a sum of cycles of different frequencies. This model is given as follows

$$\gamma_t = \sum_{j=1}^{[s/2]} \gamma_{j,t}$$

where $[s/2]$ equals $s/2$ if s is even and $(s - 1)/2$ if it is odd. The cycles $\gamma_{j,t}$ have frequencies $\lambda_j = 2\pi j/s$ and are specified by the matrix equation

$$\begin{bmatrix} \gamma_{j,t} \\ \gamma_{j,t}^* \end{bmatrix} = \begin{bmatrix} \cos \lambda_j & \sin \lambda_j \\ -\sin \lambda_j & \cos \lambda_j \end{bmatrix} \begin{bmatrix} \gamma_{j,t-1} \\ \gamma_{j,t-1}^* \end{bmatrix} + \begin{bmatrix} \omega_{j,t} \\ \omega_{j,t}^* \end{bmatrix}$$

where the disturbances $\omega_{j,t}$ and $\omega_{j,t}^*$ are assumed to be independent and, for fixed j , $\omega_{j,t}$ and $\omega_{j,t}^* \sim N(0, \sigma_\omega^2)$. If s is even, then the equation for $\gamma_{s/2,t}^*$ is not needed and $\gamma_{s/2,t}$ is given by

$$\gamma_{s/2,t} = -\gamma_{s/2,t-1} + \omega_{s/2,t}$$

The cycles $\gamma_{j,t}$ are called *harmonics*. If the seasonal component is deterministic, the decomposition of the seasonal effects into these harmonics is identical to its Fourier decomposition. In this case the

sum of squares of the seasonal factors equals the sum of squares of the amplitudes of these harmonics. In many practical situations, the contribution of the high-frequency harmonics is negligible and can be ignored, giving rise to a simpler description of the seasonal. In the case of stochastic seasonals, the situation might not be so transparent; however, similar considerations still apply. Note that if the disturbance variance $\sigma_\omega^2 = 0$, then both the dummy and the trigonometric forms of seasonal components reduce to constant seasonal effects. That is, the seasonal component reduces to a deterministic function that is completely determined by its first $s - 1$ values.

In the UCM procedure you can specify a seasonal component in a variety of ways, the **SEASON** statement being the simplest of these. The dummy and the trigonometric seasonal components discussed so far can be considered as *saturated* seasonal components that put no restrictions on the $s - 1$ seasonal values. In some cases a more parsimonious representation of the seasonal might be more appropriate. This is particularly useful for seasonal components with large season lengths. In the UCM procedure you can obtain parsimonious representations of the seasonal components by one of the following ways:

- Use a *subset* trigonometric seasonal component obtained by deleting a few of the $[s/2]$ harmonics used in its sum. For example, a slightly smoother seasonal component of length 12, corresponding to the monthly seasonality, can be obtained by deleting the highest-frequency harmonic of period 2. That is, such a seasonal component will be a sum of five stochastic cycles that have periods 12, 6, 4, 3, and 2.4. You can specify such subset seasonal components by using the **KEEPH=** or **DROPH=** option in the **SEASON** statement.
- Approximate the seasonal pattern by a suitable spline approximation. You can do this by using the **SPLINESEASON** statement.
- A *block-seasonal* pattern is a seasonal pattern where the pattern is divided into a few blocks of equal length such that the season values within a block are the same—for example, a monthly seasonal pattern that has only four different values, one for each quarter. In some situations a long seasonal pattern can be approximated by the sum of block season and a simple season, the length of the simple season being equal to the block length of the block season. You can obtain such approximation by using a combination of **BLOCKSEASON** and **SEASON** statements.
- Consider a seasonal component of a large season length as a sum of two or more seasonal components that are each of much smaller season lengths. This can be done by specifying more than one **SEASON** statements.

Note that the preceding techniques of obtaining parsimonious seasonal components can also enable you to specify seasonal components that are more *general* than the simple saturated seasonal components. For example, you can specify a saturated trigonometric seasonal component that has some of its harmonics evolving according to one disturbance variance parameter while the others evolve with another disturbance variance parameter.

Modeling an Autoregression

An autoregression of order one can be thought of as a special case of a cycle when the frequency λ is either 0 or π . Modeling this special case separately helps interpretation and parameter estimation.

The autoregression component r_t is modeled as follows

$$r_t = \rho r_{t-1} + v_t, \quad v_t \sim i.i.d. N(0, \sigma_v^2)$$

where $-1 \leq \rho < 1$. An autoregression can also provide an alternative to the **IRREGULAR** component when the model errors show some autocorrelation. You can incorporate an autoregression in your model by using the **AUTOREG** statement.

Modeling Regression Effects

A predictor variable can affect the response variable in a variety of ways. The UCM procedure enables you to model several different types of predictor-response relationships:

- The predictor-response relationship is *linear*, and the regression coefficient does not change with time. This is the simplest kind of relationship and such predictors are specified in the **MODEL** statement.
- The predictor-response relationship is *linear*, but the regression coefficient does change with time. Such predictors are specified in the **RANDOMREG** statement. Here the regression coefficient is assumed to evolve as a random walk.
- The predictor-response relationship is *nonlinear* and the relationship can change with time. This type of relationship can be approximated by an appropriate time-varying spline. Such predictors are specified in the **SPLINEREG** statement.

A response variable can depend on its own past values—that is, lagged dependent values. Such a relationship can be specified in the **DEPLAG** statement.

Modeling the Irregular Component

The components—such as trend, seasonal and regression effects, and nonstationary cycles—are used to capture the structural dynamics of a response series. In contrast, the stationary cycles and the autoregression are used to capture the transient aspects of the response series that are important for its short-range prediction but have little impact on its long-term forecasts. The irregular component represents the residual variation remaining in the response series that is modeled using an appropriate selection of structural and transient effects. In most cases, the irregular component can be assumed to be simply Gaussian white noise. In some other cases, however, the residual variation can be more complicated. In such situations, it might be necessary to model the irregular component as a stationary ARMA process. Moreover, you can use the ARMA irregular component together with the dependent lag specification (see the **DEPLAG** statement) to specify an $ARIMA(p,d,q) \times (P,D,Q)_s$ model for the response series. See the **IRREGULAR** statement for the explanation of the ARIMA notation. See **Example 31.8** for an example of modeling a series by using an $ARIMA(0,1,1) \times (0,1,1)_{12}$ model.

The Model Parameters

The parameter vector in a UCM consists of the variances of the disturbance terms of the unobserved components, the damping coefficients and frequencies in the cycles, the damping coefficient in

the autoregression, and the regression coefficients in the regression terms. These parameters are estimated by maximizing the likelihood. It is possible to restrict the values of the model parameters to user-specified values.

Model Specification

A UCM is specified by describing the components in the model. For example, consider the model

$$y_t = \mu_t + \gamma_t + \epsilon_t$$

consisting of the irregular, level, slope, and seasonal components. This model is called the basic structural model (BSM) by Harvey (1989). The syntax for a BSM with monthly seasonality of trigonometric type is as follows:

```
model y;
irregular;
level;
slope;
season length=12 type=trig;
```

Similarly the following syntax specifies a BSM with a response variable y , a regressor x , and dummy-type monthly seasonality:

```
model y = x;
irregular;
level;
slope variance=0 noest;
season length=12 type=dummy;
```

Moreover, the disturbance variance of the slope component is restricted to zero, giving rise to a local linear trend with fixed slope.

A model can contain multiple cycle and seasonal components. In such cases the model syntax contains a separate statement for each of these multiple cycle or seasonal components; for example, the syntax for a model containing irregular and level components along with two cycle components could be as follows:

```
model y = x;
irregular;
level;
cycle;
cycle;
```

The UCMs as State Space Models

The UCMs considered in PROC UCM can be thought of as special cases of more general models, called (linear) Gaussian state space models (GSSM). A GSSM can be described as follows:

$$\begin{aligned} y_t &= Z_t \alpha_t \\ \alpha_{t+1} &= T_t \alpha_t + \zeta_{t+1}, \quad \zeta_t \sim N(0, Q_t) \\ \alpha_1 &\sim N(0, P) \end{aligned}$$

The first equation, called the *observation equation*, relates the response series y_t to a state vector α_t that is usually unobserved. The second equation, called the *state equation*, describes the evolution of the state vector in time. The system matrices Z_t and T_t are of appropriate dimensions and are known, except possibly for some unknown elements that become part of the parameter vector of the model. The noise series ζ_t consists of independent, zero-mean, Gaussian vectors with covariance matrices Q_t . For most of the UCMs considered here, the system matrices Z_t and T_t , and the noise covariances Q_t , are time invariant—that is, they do not depend on time. In a few cases, however, some or all of them can depend on time. The initial state vector α_1 is assumed to be independent of the noise series, and its covariance matrix P can be partially diffuse. A random vector has a partially diffuse covariance matrix if it can be partitioned such that one part of the vector has a properly defined probability distribution, while the covariance matrix of the other part is infinite—that is, you have no prior information about this part of the vector. The covariance of the initial state α_1 is assumed to have the following form:

$$P = P_* + \kappa P_\infty$$

where P_* and P_∞ are nonnegative definite, symmetric matrices and κ is a constant that is assumed to be close to ∞ . In the case of UCMs considered here, P_∞ is always a diagonal matrix that consists of zeros and ones, and, if a particular diagonal element of P_∞ is one, then the corresponding row and column in P_* are zero.

The state space formulation of a UCM has many computational advantages. In this formulation there are convenient algorithms for estimating and forecasting the unobserved states $\{\alpha_t\}$ by using the observed series $\{y_t\}$. These algorithms also yield the in-sample and out-of-sample forecasts and the likelihood of $\{y_t\}$. The state space representation of a UCM does not need to be unique. In the representation used here, the unobserved components in the UCM often appear as elements of the state vector. This makes the elements of the state interpretable and, more important, the sample estimates and forecasts of these unobserved components are easily obtained. For additional information about the computational aspects of the state space modeling, see Durbin and Koopman (2001). Next, some notation is developed to describe the essential quantities computed during the analysis of the state space models.

Let $\{y_t, t = 1, \dots, n\}$ be the observed sample from a series that satisfies a state space model. Next, for $1 \leq t \leq n$, let the one-step-ahead forecasts of the series, the states, and their variances be defined

as follows, using the usual notation to denote the conditional expectation and conditional variance:

$$\begin{aligned}\hat{\alpha}_t &= E(\alpha_t | y_1, y_2, \dots, y_{t-1}) \\ \Gamma_t &= \text{Var}(\alpha_t | y_1, y_2, \dots, y_{t-1}) \\ \hat{y}_t &= E(y_t | y_1, y_2, \dots, y_{t-1}) \\ F_t &= \text{Var}(y_t | y_1, y_2, \dots, y_{t-1})\end{aligned}$$

These are also called the *filtered* estimates of the series and the states. Similarly, for $t \geq 1$, let the following denote the full-sample estimates of the series and the state values at time t :

$$\begin{aligned}\tilde{\alpha}_t &= E(\alpha_t | y_1, y_2, \dots, y_n) \\ \Delta_t &= \text{Var}(\alpha_t | y_1, y_2, \dots, y_n) \\ \tilde{y}_t &= E(y_t | y_1, y_2, \dots, y_n) \\ G_t &= \text{Var}(y_t | y_1, y_2, \dots, y_n)\end{aligned}$$

If the time t is in the historical period—that is, if $1 \leq t \leq n$ —then the full-sample estimates are called the *smoothed* estimates, and if t lies in the future then they are called out-of-sample forecasts. Note that if $1 \leq t \leq n$, then $\tilde{y}_t = y_t$ and $G_t = 0$, unless y_t is missing.

All the filtered and smoothed estimates ($\hat{\alpha}_t, \tilde{\alpha}_t, \dots, G_t$, and so on) are computed by using the Kalman filtering and smoothing (KFS) algorithm, which is an iterative process. If the initial state is diffuse, as is often the case for the UCMs, its treatment requires modification of the traditional KFS, which is called the diffuse KFS (DKFS). The details of DKFS implemented in the UCM procedure can be found in de Jong and Chu-Chun-Lin (2003). Additional information on the state space models can be found in Durbin and Koopman (2001). The likelihood formulas described in this section are taken from the latter reference.

In the case of diffuse initial condition, the effect of the improper prior distribution of α_1 manifests itself in the first few filtering iterations. During these initial filtering iterations the distribution of the filtered quantities remains diffuse; that is, during these iterations the one-step-ahead series and state forecast variances F_t and Γ_t have the following form:

$$\begin{aligned}F_t &= F_{*t} + \kappa F_{\infty t} \\ \Gamma_t &= \Gamma_{*t} + \kappa \Gamma_{\infty t}\end{aligned}$$

The actual number of iterations—say, I —affected by this improper prior depends on the nature of the vectors Z_t , the number of nonzero diagonal elements of P_∞ , and the pattern of missing values in the dependent series. After I iterations, $\Gamma_{\infty t}$ and $F_{\infty t}$ become zero and the one-step-ahead series and state forecasts have proper distributions. These first I iterations constitute the *initialization* phase of the DKFS algorithm. The post-initialization phase of the DKFS and the traditional KFS is the same. In the state space modeling literature the pre-initialization and post-initialization phases are some times called *pre-collapse* and *post-collapse* phases of the diffuse Kalman filtering. In certain missing value patterns it is possible for I to exceed the sample size; that is, the sample information can be insufficient to create a proper prior for the filtering process. In these cases, parameter estimation and forecasting is done on the basis of this improper prior, and some or all of the series and component

forecasts can have infinite variances (or zero precision). The forecasts that have infinite variance are set to missing. The same situation can occur if the specified model contains components that are essentially multicollinear. In these situations no residual analysis is possible; in particular, no residuals-based goodness-of-fit statistics are produced.

The log likelihood of the sample (L_∞), which takes account of this diffuse initialization step, is computed by using the one-step-ahead series forecasts as follows

$$L_\infty(y_1, \dots, y_n) = -\frac{(n-d)}{2} \log 2\pi - \frac{1}{2} \sum_{t=1}^I w_t - \frac{1}{2} \sum_{t=I+1}^n \left(\log F_t + \frac{v_t^2}{F_t} \right)$$

where d is the number of diffuse elements in the initial state α_1 , $v_t = y_t - Z_t \hat{\alpha}_t$ are the one-step-ahead residuals, and

$$\begin{aligned} w_t &= \log F_{\infty t} && \text{if } F_{\infty t} > 0 \\ &= \log F_{*t} + \frac{v_t^2}{F_{*t}} && \text{if } F_{\infty t} = 0 \end{aligned}$$

If y_t is missing at some time t , then the corresponding summand in the log likelihood expression is deleted, and the constant term is adjusted suitably. Moreover, if the initialization step does not complete—that is, if I exceeds the sample size—then the value of d is reduced to the number of diffuse states that are successfully initialized.

The portion of the log likelihood that corresponds to the post-initialization period is called the nondiffuse log likelihood (L_0). The nondiffuse log likelihood is given by

$$L_0(y_1, \dots, y_n) = -\frac{1}{2} \sum_{t=I+1}^n \left(\log F_t + \frac{v_t^2}{F_t} \right)$$

In the case of UCMs considered in PROC UCM, it often happens that the diffuse part of the likelihood, $\sum_{t=1}^I w_t$, does not depend on the model parameters, and in these cases the maximization of nondiffuse and diffuse likelihoods is equivalent. However, in some cases, such as when the model consists of dependent lags, the diffuse part does depend on the model parameters. In these cases the maximization of the diffuse and nondiffuse likelihood can produce different parameter estimates.

In some situations it is convenient to reparameterize the nondiffuse initial state covariance P_* as $\sigma^2 P_*$ and the state noise covariance Q_t as $\sigma^2 Q_t$ for some common scalar parameter σ^2 . In this case the preceding log-likelihood expression, up to a constant, can be written as

$$L_\infty(y_1, \dots, y_n) = -\frac{1}{2} \sum_{t=1}^I w_t - \frac{1}{2} \sum_{t=I+1}^n \log F_t - \frac{1}{2\sigma^2} \sum_{t=I+1}^n \frac{v_t^2}{F_t} - \frac{(n-d)}{2} \log \sigma^2$$

Solving analytically for the optimum, the maximum likelihood estimate of σ^2 can be shown to be

$$\hat{\sigma}^2 = \frac{1}{(n-d)} \sum_{t=I+1}^n \frac{v_t^2}{F_t}$$

When this expression of σ^2 is substituted back into the likelihood formula, an expression called the *profile likelihood* ($L_{profile}$) of the data is obtained:

$$-2L_{profile}(y_1, \dots, y_n) = \sum_{t=1}^I w_t + \sum_{t=I+1}^n \log F_t + (n-d) \log \left(\sum_{t=I+1}^n \frac{v_t^2}{F_t} \right)$$

In some situations the parameter estimation is done by optimizing the profile likelihood (see the section “[Parameter Estimation by Profile Likelihood Optimization](#)” on page 1990 and the **PROFILE** option in the ESTIMATE statement).

In the remainder of this section the state space formulation of UCMs is further explained by using some particular UCMs as examples. The examples show that the state space formulation of the UCMs depends on the components in the model in a simple fashion; for example, the system matrix T is usually a block diagonal matrix with blocks that correspond to the components in the model. The only exception to this pattern is the UCMs that consist of the lags of dependent variable. This case is considered at the end of the section.

In what follows, $Diag [a, b, \dots]$ denotes a diagonal matrix with diagonal entries $[a, b, \dots]$, and the transpose of a matrix T is denoted as T' .

Locally Linear Trend Model

Recall that the dynamics of the locally linear trend model are

$$\begin{aligned} y_t &= \mu_t + \epsilon_t \\ \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t \\ \beta_t &= \beta_{t-1} + \xi_t \end{aligned}$$

Here y_t is the response series and ϵ_t , η_t , and ξ_t are independent, zero-mean Gaussian disturbance sequences with variances σ_ϵ^2 , σ_η^2 , and σ_ξ^2 , respectively. This model can be formulated as a state space model where the state vector $\alpha_t = [\epsilon_t \ \mu_t \ \beta_t]'$ and the state noise $\zeta_t = [\epsilon_t \ \eta_t \ \xi_t]'$. Note that the elements of the state vector are precisely the unobserved components in the model. The system matrices T and Z and the noise covariance Q corresponding to this choice of state and state noise vectors can be seen to be time invariant and are given by

$$Z = [1 \ 1 \ 0], \quad T = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix} \quad \text{and} \quad Q = Diag [\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2]$$

The distribution of the initial state vector α_1 is diffuse, with $P_* = Diag [\sigma_\epsilon^2, 0, 0]$ and $P_\infty = Diag [0, 1, 1]$. The parameter vector θ consists of all the disturbance variances—that is, $\theta = (\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2)$.

Basic Structural Model

The basic structural model (BSM) is obtained by adding a seasonal component, γ_t , to the local level model. In order to economize on the space, the state space formulation of a BSM with a relatively

short season length, season length = 4 (quarterly seasonality), is considered here. The pattern for longer season lengths such as 12 (monthly) and 52 (weekly) is easy to see.

Let us first consider the dummy form of seasonality. In this case the state and state noise vectors are $\alpha_t = [\epsilon_t \mu_t \beta_t \gamma_{1,t} \gamma_{2,t} \gamma_{3,t}]'$ and $\zeta_t = [\epsilon_t \eta_t \xi_t \omega_t 0 0]'$, respectively. The first three elements of the state vector are the irregular, level, and slope components, respectively. The remaining elements, $\gamma_{i,t}$, are lagged versions of the seasonal component γ_t . $\gamma_{1,t}$ corresponds to lag zero—that is, the same as γ_t , $\gamma_{2,t}$ to lag 1 and $\gamma_{3,t}$ to lag 2. The system matrices are

$$Z = [1 \ 1 \ 0 \ 1 \ 0 \ 0], \quad T = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & -1 & -1 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}$$

and $Q = \text{Diag}[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, 0, 0]$. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1, 1, 1, 1]$.

In the case of the trigonometric type of seasonality, $\alpha_t = [\epsilon_t \mu_t \beta_t \gamma_{1,t} \gamma_{1,t}^* \gamma_{2,t}]'$ and $\zeta_t = [\epsilon_t \eta_t \xi_t \omega_{1,t} \omega_{1,t}^* \omega_{2,t}]'$. The disturbance sequences, $\omega_{j,t}$, $1 \leq j \leq 2$, and $\omega_{1,t}^*$, are independent, zero-mean, Gaussian sequences with variance σ_ω^2 . The system matrices are

$$Z = [1 \ 1 \ 0 \ 1 \ 0 \ 1], \quad T = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \cos \lambda_1 & \sin \lambda_1 & 0 \\ 0 & 0 & 0 & -\sin \lambda_1 & \cos \lambda_1 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cos \lambda_2 \end{bmatrix}$$

and $Q = \text{Diag}[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, \sigma_\omega^2, \sigma_\omega^2]$. Here $\lambda_j = (2\pi j)/4$. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1, 1, 1, 1]$. The parameter vector in both the cases is $\theta = (\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2)$.

Seasons with Blocked Seasonal Values

Block seasonals are special seasonal components that impose a special block structure on the seasonal effects. Let us consider a BSM with monthly seasonality that has a quarterly block structure—that is, months within the same quarter are assumed to have identical effects except for some random perturbation. Such a seasonal component is a block seasonal with block size m equal to 3 and the number of blocks k equal to 4. The state space structure for such a model with dummy-type seasonality is as follows: The state and state noise vectors are $\alpha_t = [\epsilon_t \mu_t \beta_t \gamma_{1,t} \gamma_{2,t} \gamma_{3,t}]'$ and $\zeta_t = [\epsilon_t \eta_t \xi_t \omega_t 0 0]'$, respectively. The first three elements of the state vector are the irregular, level, and slope components, respectively. The remaining elements, $\gamma_{i,t}$, are lagged versions of the seasonal component γ_t . $\gamma_{1,t}$ corresponds to lag zero—that is, the same as γ_t , $\gamma_{2,t}$ to lag m and $\gamma_{3,t}$

to lag $2m$. All the system matrices are time invariant, except the matrix T . They can be seen to be $Z = [1\ 1\ 0\ 1\ 0\ 0]$, $Q = \text{Diag} [\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, 0, 0]$, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & -1 & -1 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}$$

when t is a multiple of the block size m , and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

otherwise. Note that when t is not a multiple of m , the portion of the T_t matrix corresponding to the seasonal is identity. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag} [\sigma_\epsilon^2, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag} [0, 1, 1, 1, 1, 1]$.

Similarly in the case of the trigonometric form of seasonality, $\alpha_t = [\epsilon_t \mu_t \beta_t \gamma_{1,t} \gamma_{1,t}^* \gamma_{2,t}]'$ and $\zeta_t = [\epsilon_t \eta_t \xi_t \omega_{1,t} \omega_{1,t}^* \omega_{2,t}]'$. The disturbance sequences, $\omega_{j,t}$, $1 \leq j \leq 2$, and $\omega_{1,t}^*$, are independent, zero-mean, Gaussian sequences with variance σ_ω^2 . $Z = [1\ 1\ 0\ 1\ 0\ 1]$, $Q = \text{Diag} [\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, \sigma_\omega^2, \sigma_\omega^2]$, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \cos \lambda_1 & \sin \lambda_1 & 0 \\ 0 & 0 & 0 & -\sin \lambda_1 & \cos \lambda_1 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cos \lambda_2 \end{bmatrix}$$

when t is a multiple of the block size m , and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

otherwise. As before, when t is not a multiple of m , the portion of the T_t matrix corresponding to the seasonal is identity. Here $\lambda_j = (2\pi j)/4$. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag} [\sigma_\epsilon^2, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag} [0, 1, 1, 1, 1, 1]$. The parameter vector in both the cases is $\theta = (\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2)$.

Cycles and Autoregression

The preceding examples have illustrated how to build a state space model corresponding to a UCM that includes components such as irregular, trend, and seasonal. There you can see that the state vector and the system matrices have a simple block structure with blocks corresponding to the components in the model. Therefore, here only a simple model consisting of a single cycle and an irregular component is considered. The state space form for more complex UCMs consisting of multiple cycles and other components can be easily deduced from this example.

Recall that a stochastic cycle ψ_t with frequency λ , $0 < \lambda < \pi$, and damping coefficient ρ can be modeled as

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos \lambda & \sin \lambda \\ -\sin \lambda & \cos \lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} \nu_t \\ \nu_t^* \end{bmatrix}$$

where ν_t and ν_t^* are independent, zero-mean, Gaussian disturbances with variance σ_ν^2 . In what follows, a state space form for a model consisting of such a stochastic cycle and an irregular component is given.

The state vector $\alpha_t = [\epsilon_t \ \psi_t \ \psi_t^*]'$, and the state noise vector $\zeta_t = [\epsilon_t \ \nu_t \ \nu_t^*]'$. The system matrices are

$$Z = [1 \ 1 \ 0] \quad T = \begin{bmatrix} 0 & 0 & 0 \\ 0 & \rho \cos \lambda & \rho \sin \lambda \\ 0 & -\rho \sin \lambda & \rho \cos \lambda \end{bmatrix} \quad Q = \text{Diag} [\sigma_\epsilon^2, \sigma_\nu^2, \sigma_\nu^2]$$

The distribution of the initial state vector α_1 is proper, with $P_* = \text{Diag} [\sigma_\epsilon^2, \sigma_\psi^2, \sigma_\psi^2]$, where $\sigma_\psi^2 = \sigma_\nu^2(1 - \rho^2)^{-1}$. The parameter vector $\theta = (\sigma_\epsilon^2, \rho, \lambda, \sigma_\nu^2)$.

An autoregression r_t can be considered as a special case of cycle with frequency λ equal to 0 or π . In this case the equation for ψ_t^* is not needed. Therefore, for a UCM consisting of an autoregressive component and an irregular component, the state space model simplifies to the following form.

The state vector $\alpha_t = [\epsilon_t \ r_t]'$, and the state noise vector $\zeta_t = [\epsilon_t \ \nu_t]'$. The system matrices are

$$Z = [1 \ 1], \quad T = \begin{bmatrix} 0 & 0 \\ 0 & \rho \end{bmatrix} \quad \text{and} \quad Q = \text{Diag} [\sigma_\epsilon^2, \sigma_\nu^2]$$

The distribution of the initial state vector α_1 is proper, with $P_* = \text{Diag} [\sigma_\epsilon^2, \sigma_r^2]$, where $\sigma_r^2 = \sigma_\nu^2(1 - \rho^2)^{-1}$. The parameter vector $\theta = (\sigma_\epsilon^2, \rho, \sigma_\nu^2)$.

Incorporating Predictors of Different Kinds

In the UCM procedure, predictors can be incorporated in a UCM in a variety of ways: simple time-invariant linear predictors are specified in the **MODEL** statement, predictors with time-varying coefficients can be specified in the **RANDOMREG** statement, and predictors that have a nonlinear relationship with the response variable can be specified in the **SPLINEREG** statement. As with earlier examples, how to obtain a state space form of a UCM consisting of such variety of predictors is illustrated using a simple special case. Consider a random walk trend model with predictors

x , u_1 , u_2 , and v . Let us assume that x is a simple regressor specified in the MODEL statement, u_1 and u_2 are random regressors with time-varying regression coefficients that are specified in the same RANDOMREG statement, and v is a nonlinear regressor specified on a SPLINEREG statement. Let us further assume that the spline associated with v has degree one and is based on two internal knots. As explained in the section “SPLINEREG Statement” on page 1970, using v is equivalent to using $(nknots + degree) = (2 + 1) = 3$ derived (random) regressors: say, s_1, s_2, s_3 . In all there are $(1 + 2 + 3) = 6$ regressors, the first one being a simple regressor and the others being time-varying coefficient regressors. The time-varying regressors are in two groups, the first consisting of u_1 and u_2 and the other consisting of s_1, s_2 , and s_3 . The dynamics of this model are as follows:

$$\begin{aligned}
 y_t &= \mu_t + \beta x_t + \kappa_{1t} u_{1t} + \kappa_{2t} u_{2t} + \sum_{i=1}^3 \gamma_{it} s_{it} + \epsilon_t \\
 \mu_t &= \mu_{t-1} + \eta_t \\
 \kappa_{1t} &= \kappa_{1(t-1)} + \xi_{1t} \\
 \kappa_{2t} &= \kappa_{2(t-1)} + \xi_{2t} \\
 \gamma_{1t} &= \gamma_{1(t-1)} + \zeta_{1t} \\
 \gamma_{2t} &= \gamma_{2(t-1)} + \zeta_{2t} \\
 \gamma_{3t} &= \gamma_{3(t-1)} + \zeta_{3t}
 \end{aligned}$$

All the disturbances $\epsilon_t, \eta_t, \xi_{1t}, \xi_{2t}, \zeta_{1t}, \zeta_{2t}$, and ζ_{3t} are independent, zero-mean, Gaussian variables, where ξ_{1t}, ξ_{2t} share a common variance parameter σ_ξ^2 and $\zeta_{1t}, \zeta_{2t}, \zeta_{3t}$ share a common variance σ_ζ^2 . These dynamics can be captured in the state space form by taking state $\alpha_t = [\epsilon_t \mu_t \beta \kappa_{1t} \kappa_{2t} \gamma_{1t} \gamma_{2t} \gamma_{3t}]'$, state disturbance $\zeta_t = [\epsilon_t \eta_t 0 \xi_{1t} \xi_{2t} \zeta_{1t} \zeta_{2t} \zeta_{3t}]'$, and the system matrices

$$\begin{aligned}
 Z_t &= [1 \ 1 \ x_t \ u_{1t} \ u_{2t} \ s_{1t} \ s_{2t} \ s_{3t}] \\
 T &= \text{Diag}[0, 1, 1, 1, 1, 1, 1, 1] \\
 Q &= \text{Diag}[\sigma_\epsilon^2, \sigma_\eta^2, 0, \sigma_\xi^2, \sigma_\xi^2, \sigma_\zeta^2, \sigma_\zeta^2, \sigma_\zeta^2]
 \end{aligned}$$

Note that the regression coefficients are elements of the state vector and that the system vector Z_t is not time invariant. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1, 1, 1, 1, 1, 1]$. The parameters of this model are the disturbance variances, $\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2$, and σ_ζ^2 , which get estimated by maximizing the likelihood. The regression coefficients, time-invariant β and time-varying $\kappa_{1t}, \kappa_{2t}, \gamma_{1t}, \gamma_{2t}$ and γ_{3t} , get implicitly estimated during the state estimation (smoothing).

Reporting Parameter Estimates for Random Regressors

If the random walk disturbance variance associated with a random regressor is held fixed at zero, then its coefficient is no longer time-varying. In the UCM procedure the random regressor parameter estimates are reported differently if the random walk disturbance variance associated with a random regressor is held fixed at zero. The following points explain how the parameter estimates are reported in the parameter estimates table and in the OUTEST= data set.

- If the random walk disturbance variance associated with a random regressor is not held fixed, then its estimate is reported in the parameter estimates table and in the OUTEST= data set.
- If more than one random regressor is specified in a **RANDOMREG** statement, then the first regressor in the list is used as a representative of the list while reporting the corresponding common variance parameter estimate.
- If the random walk disturbance variance is held fixed at zero, then the parameter estimates table and the OUTEST= data set contain the corresponding regression parameter estimate rather than the variance parameter estimate.
- Similar considerations apply in the case of the derived random regressors associated with a spline-regressor.

ARMA Irregular Component

The state space form for the irregular component that follows an $\text{ARMA}(p,q) \times (P,Q)_s$ model is described in this section. The notation for ARMA models is explained in the **IRREGULAR** statement. A number of alternate state space forms are possible in this case; the one given here is based on Jones (1980). With slight abuse of notation, let $p = p + sP$ denote the effective autoregressive order and $q = q + sQ$ denote the effective moving average order of the model. Similarly, let ϕ be the effective autoregressive polynomial and θ be the effective moving average polynomial in the backshift operator with coefficients ϕ_1, \dots, ϕ_p and $\theta_1, \dots, \theta_q$, obtained by multiplying the respective nonseasonal and seasonal factors. Then, a random sequence ϵ_t that follows an $\text{ARMA}(p,q) \times (P,Q)_s$ model with a white noise sequence a_t has a state space form with state vector of size $m = \max(p, q + 1)$. The system matrices, which are time invariant, are as follows: $Z = [1 \ 0 \ \dots \ 0]$. The state transition matrix T , in a blocked form, is given by

$$T = \begin{bmatrix} 0 & I_{m-1} \\ \phi_m & \dots & \phi_1 \end{bmatrix}$$

where $\phi_i = 0$ if $i > p$ and I_{m-1} is an $(m - 1)$ dimensional identity matrix. The covariance of the state disturbance matrix $Q = \sigma^2 \psi \psi'$ where σ^2 is the variance of the white noise sequence a_t and the vector $\psi = [\psi_0 \ \dots \ \psi_{m-1}]'$ contains the first m values of the impulse response function—that is, the first m coefficients in the expansion of the ratio θ/ϕ . Since ϵ_t is a stationary sequence, the initial state is nondiffuse and $P_\infty = 0$. The description of P_* , the covariance matrix of the initial state, is a little involved; the details are given in Jones (1980).

Models with Dependent Lags

The state space form of a UCM consisting of the lags of the dependent variable is quite different from the state space forms considered so far. Let us consider an example to illustrate this situation. Consider a model that has random walk trend, two simple time-invariant regressors, and that also includes a few—say, k —lags of the dependent variable. That is,

$$y_t = \sum_{i=1}^k \phi_i y_{t-i} + \mu_t + \beta_1 x_{1t} + \beta_2 x_{2t} + \epsilon_t$$

$$\mu_t = \mu_{t-1} + \eta_t$$

The state space form of this augmented model can be described in terms of the state space form of a model that has random walk trend with two simple time-invariant regressors. A superscript dagger (\dagger) has been added to distinguish the augmented model state space entities from the corresponding entities of the state space form of the random walk with predictors model. With this notation, the state vector of the augmented model $\alpha_t^\dagger = \begin{bmatrix} \alpha_t' y_t y_{t-1} \dots y_{t-k+1} \end{bmatrix}'$ and the new state noise vector $\zeta_t^\dagger = \begin{bmatrix} \zeta_t' u_t 0 \dots 0 \end{bmatrix}'$, where u_t is the matrix product $Z_t \zeta_t$. Note that the length of the new state vector is $k + \text{length}(\alpha_t) = k + 4$. The new system matrices, in block form, are

$$Z_t^\dagger = [0 \ 0 \ 0 \ 0 \ 1 \ \dots \ 0], \quad T_t^\dagger = \begin{bmatrix} T_t & 0 & \dots & 0 \\ Z_{t+1} T_t & \phi_1 & \dots & \phi_k \\ 0 & I_{k-1, k-1} & & 0 \end{bmatrix}$$

where $I_{k-1, k-1}$ is the $k - 1$ dimensional identity matrix and

$$Q_t^\dagger = \begin{bmatrix} Q_t & Q_t Z_t' & 0 \\ Z_t Q_t & Z_t Q_t Z_t' & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

Note that the T and Q matrices of the random walk with predictors model are time invariant, and in the expressions above their time indices are kept because they illustrate the pattern for more general models. The initial state vector is diffuse, with

$$P_*^\dagger = \begin{bmatrix} P_* & 0 \\ 0 & 0 \end{bmatrix}, \quad P_\infty^\dagger = \begin{bmatrix} P_\infty & 0 \\ 0 & I_{k, k} \end{bmatrix}$$

The parameters of this model are the disturbance variances σ_ϵ^2 and σ_η^2 , the lag coefficients $\phi_1, \phi_2, \dots, \phi_k$, and the regression coefficients β_1 and β_2 . As before, the regression coefficients get estimated during the state smoothing, and the other parameters are estimated by maximizing the likelihood.

Outlier Detection

In time series analysis it is often useful to detect changes over time in the characteristics of the response series. In the UCM procedure you can search for two types of changes, additive outliers (AO) and level shifts (LS). An additive outlier is an unusual value in the series, the cause of which might be a data recording error or a temporary shock to the series generation process. A level shift represents a permanent shift, either up or down, in the level of the series. You can control different aspects of the outlier search, such as the significance level of the reported outliers, by choosing different options in the **OUTLIER** statement. The search for AOs is done by default, whereas the **CHECKBREAK** option in the **LEVEL** statement must be used to turn on the search for LSs.

The outlier detection process implemented in the UCM procedure is based on de Jong and Penzer (1998). In this approach the fitted model is taken to be the *null* model, and the series values and level shifts that are not adequately accounted for by the null model are flagged as outliers. The unusualness of a response series value at a particular time point t_0 , with respect to the fitted model, can be judged by estimating its value based on the rest of the data (that is, the series obtained by *deleting* the series

value at t_0) and comparing the estimated value to the observed value. If the difference between the estimated and observed values is statistically significant, then such value can be regarded as an AO. Note that this difference between the estimated and observed values is also the regression coefficient of a *dummy* regressor that takes the value 1.0 at t_0 and is 0.0 elsewhere, assuming such a regressor is added to the null model. In this way the series value at t_0 is regarded as AO if the regression coefficient of this dummy regressor is significant. Similarly, you can say that a level shift has occurred at a time point t_0 if the regression coefficient of a regressor, which is 0.0 before t_0 and 1.0 at t_0 and thereafter, is statistically significant. De Jong and Penzer (1998) provide an efficient way to compute such AO and LS regression coefficients and their standard errors at all time points in the series. The outlier summary table, which is produced by default, simply lists the most statistically significant candidates among these.

Missing Values

Embedded missing values in the dependent variable usually cause no problems in UCM modeling. However, no embedded missing values are allowed in the predictor variables. Certain patterns of missing values in the dependent variable can lead to failure of the initialization step of the diffuse Kalman filtering for some models. For example, if in a monthly series all values are missing for a certain month—say, May—then a BSM with monthly seasonality leads to such a situation. However, in this case the initialization step can complete successfully for a nonseasonal model such as local linear model.

Parameter Estimation

The parameter vector in a UCM consists of the variances of the disturbance terms of the unobserved components, the damping coefficients and frequencies in the cycles, the damping coefficient in the autoregression, the lag coefficients of the dependent lags, and the regression coefficients in the regression terms. The regression coefficients are always part of the state vector and are estimated by state smoothing. The remaining parameters are estimated by maximizing either the full diffuse likelihood or the nondiffuse likelihood. The decision to use the full diffuse likelihood or the nondiffuse likelihood depends on the presence or absence of the dependent lag coefficients in the parameter vector. If the parameter vector does not contain any dependent lag coefficients, then the full diffuse likelihood is used. If, on the other hand, the parameter vector does contain some dependent lag coefficients, then the parameters are estimated by maximizing the nondiffuse likelihood. The optimization of the full diffuse likelihood is often unstable when the parameter vector contains dependent lag coefficients. In this sense, when the parameter vector contains dependent lag coefficients, the parameter estimates are not true maximum likelihood estimates.

The optimization of the likelihood, either full or nondiffuse, is carried out using one of several nonlinear optimization algorithms. The user can control many aspects of the optimization process by using the `NLOPTIONS` statement and by providing the starting values of the parameters while specifying the corresponding components. However, in most cases the default settings work quite well. The optimization process is not guaranteed to converge to a maximum likelihood estimate. In

most cases the difficulties in parameter estimation are associated with the specification of a model that is not appropriate for the series being modeled.

Parameter Estimation by Profile Likelihood Optimization

If a disturbance variance, such as the disturbance variance of the irregular component, is a part of the UCM and is a free parameter, then it can be profiled out of the likelihood. This means solving analytically for its optimum and plugging this expression back into the likelihood formula, giving rise to the so-called *profile* likelihood. The expression of the profile likelihood and the MLE of the profiled variance are given earlier in the section “The UCMs as State Space Models” on page 1979, where the computation of the likelihood of the state space model is also discussed.

In some situations the optimization of the profile likelihood can be more efficient because the number of parameters to optimize is reduced by one; however, for a variety of reasons such gains might not always be observed. Moreover, in theory the estimates obtained by optimizing the profile likelihood and the usual likelihood should be the same, but in practice this might not hold because of numerical rounding and other conditions.

In the UCM procedure, by default the usual likelihood is optimized if any of the disturbance variance parameters is held fixed to a nonzero value by using the NOEST option in the corresponding component statement. In other cases the decision whether to optimize the profile likelihood or the usual likelihood is based on several factors that are difficult to document. You can choose which likelihood to optimize during parameter estimation by specifying the PROFILE option for the profile likelihood optimization or the NOPROFILE option for the usual likelihood optimization. In the presence of the PROFILE option, the disturbance variance to profile is checked in a specific order, so that if the irregular component disturbance variance is free then it is always chosen. The situation in other cases is more complicated.

Profiling in the Presence of Fixed Variance Parameters

Note that when the parameter estimation is done by optimizing the profile likelihood, the interpretation of the variance parameters that are held fixed to nonzero values changes. In the presence of the PROFILE option, the disturbance variances that are held at a fixed value by using the NOEST option in their respective component statements are interpreted as being restricted to be that fixed multiple of the profiled variance rather than being fixed at that nominal value. That is, implicitly, the parameter estimation is done under the restriction of holding the disturbance variance *ratio* fixed at a given value rather than the disturbance variance itself. See Example 31.5 for an example of this type of restriction to obtain a UC model that is equivalent to the famous Hodrick-Prescott filter.

t values

The *t* values reported in the table of parameter estimates are approximations whose accuracy depends on the validity of the model, the nature of the model, and the length of the observed series. The distributional properties of the maximum likelihood estimates of general unobserved components models have not been explored fully; therefore the probability values that correspond to a *t* distribution should be interpreted carefully, as they can be misleading. This is particularly true if the parameters

in question are close to the boundary of the parameter space. The two sources by Harvey (1989, 2001) are good references for information about this topic. For some parameters, such as, the cycle period, the reported t values are uninformative because comparison of the estimated parameter with zero is never needed. In such cases the t values and the corresponding probability values should be ignored.

Computational Issues

Convergence Problems

As explained in the section “[Parameter Estimation](#)” on page 1989, the model parameters are estimated by nonlinear optimization of the likelihood. This process is not guaranteed to succeed. For some data sets, the optimization algorithm can fail to converge. Nonconvergence can result from a number of causes, including flat or ridged likelihood surfaces and ill-conditioned data. It is also possible for the algorithm to converge to a point that is not the global optimum of the likelihood.

If you experience convergence problems, the following points might be helpful:

- Data that are extremely large or extremely small can adversely affect results because of the internal tolerances used during the filtering steps of the likelihood calculation. Rescaling the data can improve stability.
- Examine your model for redundancies in the included components and regressors. If some of the included components or regressors are nearly collinear to each other, then the optimization process can become unstable.
- Experimenting with different options offered by the `NLOPTIONS` statement can help.
- Lack of convergence can indicate model misspecification or a violation of the normality assumption.

Computer Resource Requirements

The computing resources required for the UCM procedure depend on several factors. The memory requirement for the procedure is largely dependent on the number of observations to be processed and the size of the state vector underlying the specified model. If n denotes the sample size and m denotes the size of the state vector, the memory requirement for the smoothing stage of the Kalman filter is of the order of $6 \times 8 \times n \times m^2$ bytes, ignoring the lower-order terms. If the smoothed component estimates are not needed then the memory requirement is of the order of $6 \times 8 \times (m^2 + n)$ bytes. Besides m and n , the computing time for the parameter estimation depends on the type of components included in the model. For example, the parameter estimation is usually faster if the model parameter vector consists only of disturbance variances, because in this case there is an efficient way to compute the likelihood gradient.

Displayed Output

The default printed output produced by the UCM procedure is described in the following list:

- brief information about the input data set, including the data set name and label, and the name of the ID variable specified in the ID statement
- summary statistics for the data in the estimation and forecast spans, including the names of the variables in the model, their categorization as dependent or predictor, the index of the beginning and ending observations in the spans, the total number of observations and the number of missing observations, the smallest and largest measurements, and the mean and standard deviation
- information about the model parameters at the start of the model-fitting stage, including the fixed parameters in the model and the initial estimates of the free parameters in the model
- convergence status of the likelihood optimization process if any parameter estimation is done
- estimates of the free parameters at the end of the model fitting-stage, including the parameter estimates, their approximate standard errors, t statistics, and the approximate p -value
- the likelihood-based goodness-of-fit statistics, including the full likelihood, the portion of the likelihood corresponding to the diffuse initialization, the sum of squares of residuals normalized by their standard errors, and the information criteria: AIC, AICC, HQIC, BIC, and CAIC
- the fit statistics that are based on the raw residuals (observed minus predicted), including the mean squared error (MSE), the root mean squared error (RMSE), the mean absolute percentage error (MAPE), the maximum percentage error (MAXPE), the R square, the adjusted R square, the random walk R square, and Amemiya's R square
- the significance analysis of the components included in the model that is based on the estimation span
- brief information about the components included in the model
- additive outliers in the series, if any are detected
- the multistep series forecasts
- post-sample-prediction analysis table that compares the multistep forecasts with the observed series values, if the BACK= option is used in the FORECAST statement

Statistical Graphics

This section provides information about the basic ODS statistical graphics produced by the UCM procedure. To request graphics with PROC UCM, you must first enable ODS Graphics by specifying

the `ODS GRAPHICS ON;` statement. See Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*), for more information.

You can obtain most plots relevant to the specified model by using the global `PLOTS=` option in the `PROC UCM` statement. The plot of series forecasts in the forecast horizon is produced by default. You can further control the production of individual plots by using the `PLOT=` options in the different statements.

The main types of plots available are as follows:

- Time series plots of the component estimates, either filtered or smoothed, can be requested by using the `PLOT=` option in the respective component statements. For example, the use of `PLOT=SMOOTH` option in a `CYCLE` statement produces a plot of smoothed estimate of that cycle.
- Residual plots for model diagnostics can be obtained by using the `PLOT=` option in the `ESTIMATE` statement.
- Plots of series forecasts and model decompositions can be obtained by using the `PLOT=` option in the `FORECAST` statement.

The following example is a simple illustration of the available plot options.

Analysis of Sunspot Data: Illustration of ODS Graphics

In this example a well-known series, Wolfer’s sunspot data (Anderson 1971), is considered. The data consist of yearly sunspot numbers recorded from 1749 to 1924. These sunspot numbers are known to have a cyclical pattern with a period of about eleven years. The following `DATA` step creates the input data set:

```
data sunspot;
  input year wolfer @@;
  year = mdy(1,1, year);
  format year year4.;
datalines;
1749  809 1750  834 1751  477 1752  478 1753  307 1754  122 1755   96
1756  102 1757  324 1758  476 1759  540 1760  629 1761  859 1762  612
... more lines ...
```

The following statements specify a UCM that includes a cycle component and a random walk trend component:

```
ods graphics on;
proc ucm data=sunspot;
  id year interval=year;
  model wolfer;
  irregular;
  level ;
  cycle plot=(filter smooth);
  estimate back=24 plot=(loess panel cusum wn);
  forecast back=24 lead=24 plot=(forecasts decomp);
run;
```

The following subsections explain the graphics produced by the above statements.

Component Plots

The plots in [Figure 31.8](#) and [Figure 31.9](#), produced by specifying `PLOT=(FILTER SMOOTH)` in the `CYCLE` statement, show the filtered and smoothed estimates, respectively, of the cycle component in the model. Note that the smoothed estimate appears smoother than the filtered estimate. This is always true because the filtered estimate of a component at time t is based on the observations prior to time t —that is, it uses measurements from the first observation up to the $(t - 1)$ th observation. On the other hand, the corresponding smoothed estimate uses all the available observations—that is, all the measurements from the first observation to the last. This makes the smoothed estimate of the component more precise than the filtered estimate for the time points within historical period. In the forecast horizon, both filtered and smoothed estimates are identical, being based on the same set of observations.

Figure 31.8 Sunspots Series: Filtered Cycle

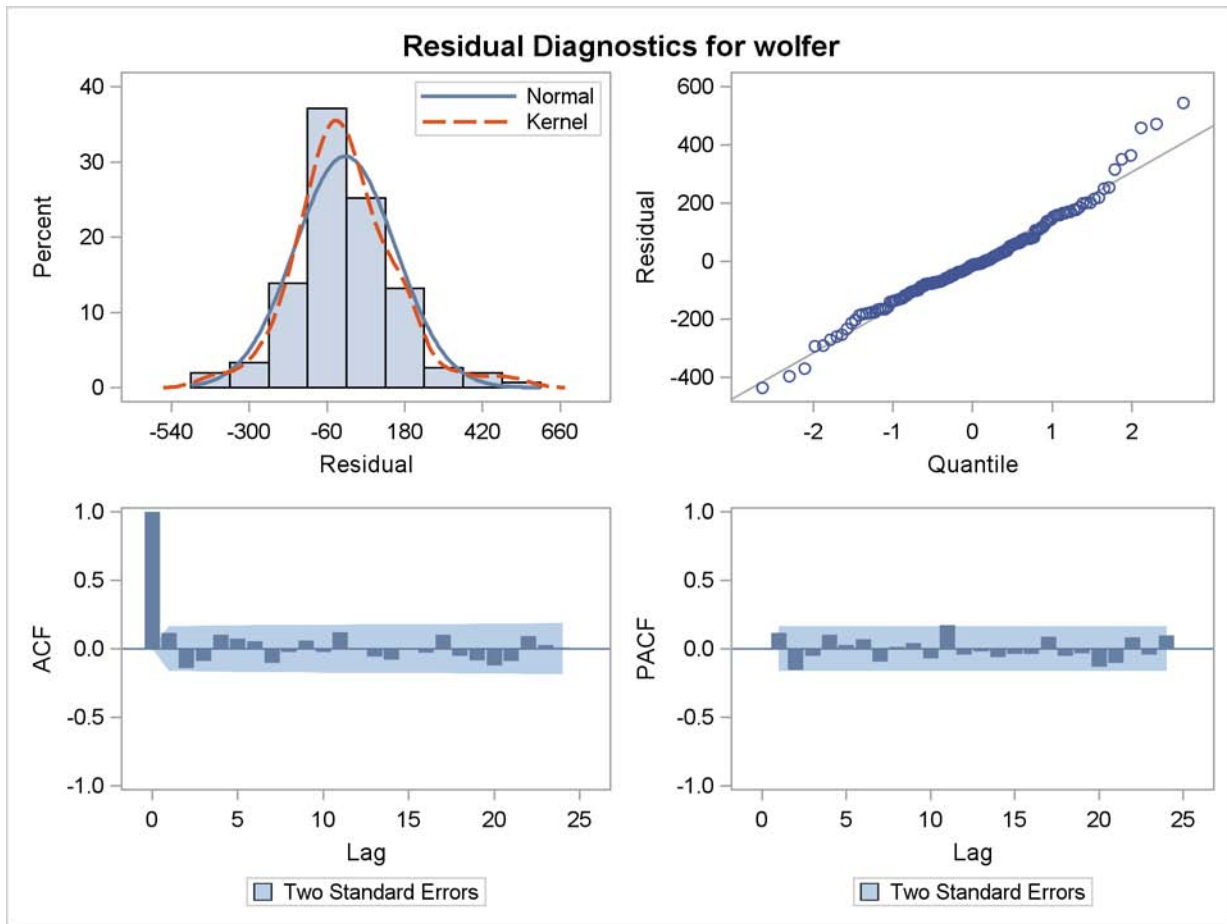

Figure 31.9 Sunspots Series: Smoothed Cycle

Residual Diagnostics

If the fitted model is appropriate for the given data, then the corresponding one-step-ahead residuals should be approximately *white*—that is, uncorrelated—and approximately normal. Moreover, the residuals should not display any discernible pattern. You can detect departures from these conditions graphically. Different residual diagnostic plots can be requested by using the PLOT= option in the ESTIMATE statement.

The normality can be checked by examining the histogram and the normal quantile plot of residuals. The whiteness can be checked by examining the ACF and PACF plots that show the sample autocorrelation and sample partial-autocorrelation at different lags. The diagnostic panel shown in Figure 31.10, produced by specifying PLOT= PANEL, contains these four plots.

Figure 31.10 Sunspots Series: Residual Diagnostics

The residual histogram and Q-Q plot show no serious violation of normality. The histogram appears reasonably symmetric and follows the overlaid normal density curve reasonably closely. Similarly in the Q-Q plot the residuals follow the reference line fairly closely. The ACF and PACF plots also do not exhibit any violation of the whiteness assumption; the correlations at all nonzero lags seem to be insignificant.

The residual whiteness can also be formally tested by using the Ljung-Box portmanteau test. The plot in Figure 31.11, produced by specifying PLOT=WN, shows the p -values of the Ljung-Box test statistics at different lags. In these plots the p -values for the first few lags, equal to the number of estimated parameters in the model, are not shown because they are always missing. This portion of the plot is shaded blue to indicate this fact. In the case of this model, five parameters are estimated so the p -values for the first five lags are not shown. The p -values are displayed on a log scale in such a way that higher bars imply more extreme test statistics. In this plot some early p -values appear extreme. However, these p -values are based on large sample theory, which suggests that these statistics should be examined for lags larger than the square root of sample size. In this example it means that the p -values for the first $\sqrt{154} \approx 12$ lags can be ignored. With this consideration, the plot shows no violation of whiteness since the p -values after the 12th lag do not appear extreme.

Figure 31.11 Sunspots Series: Ljung-Box Portmanteau Test

The plot in Figure 31.12, produced by specifying PLOT=LOESS, shows the residuals plotted against time with an overlaid LOESS curve. This plot is useful for checking whether any discernible pattern remains in the residuals. Here again, no significant pattern appears to be present.

Figure 31.12 Sunspots Series: Residual Loess Plot

The plot in [Figure 31.13](#), produced by specifying `PLOT=CUSUM`, shows the cumulative residuals plotted against time. This plot is useful for checking structural breaks. Here, there appears to be no evidence of structural break since the cumulative residuals remain within the confidence band throughout the sample period. Similarly you can request a plot of the squared cumulative residuals by specifying `PLOT=CUSUMSQ`.

Figure 31.13 Sunspots Series: CUSUM Plot

Brockwell and Davis (1991) can be consulted for additional information on diagnosing residuals. For more information on CUSUM and CUSUMSQ plots, you can consult Harvey (1989).

Forecast and Series Decomposition Plots

You can use the PLOT= option in the FORECAST statement to obtain the series forecast plot and the series decomposition plots. The series decomposition plots show the result of successively adding different components in the model starting with the trend component. The IRREGULAR component is left out of this process. The following two plots, produced by specifying PLOT=DECOMP, show the results of successive component addition for this example. The first plot, shown in Figure 31.14, shows the smoothed trend component and the second plot, shown in Figure 31.15, shows the sum of smoothed trend and cycle.

Figure 31.14 Sunspots Series: Smoothed Trend

Figure 31.15 Sunspots Series: Smoothed Trend plus Cycle

Finally, Figure 31.16 shows the forecast plot.

Figure 31.16 Sunspots Series: Series Forecasts

ODS Table Names

The UCM procedure assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 31.2](#).

Table 31.2 ODS Tables Produced by PROC UCM

ODS Table Name	Description	Statement	Option
Tables Summarizing the Estimation and Forecast Spans			
EstimationSpan	Estimation span summary information		default
ForecastSpan	Forecast span summary information		default
Tables Related to Model Parameters			

Table 31.2 *continued*

ODS Table Name	Description	Statement	Option
ConvergenceStatus	Convergence status of the estimation process		default
FixedParameters	Fixed parameters in the model		default
InitialParameters	Initial estimates of the free parameters		default
ParameterEstimates	Final estimates of the free parameters		default
Tables Related to Model Information and Diagnostics			
BlockSeasonDescription	Information about the block seasonals in the model		default
ComponentSignificance	Significance analysis of the components in the model		default
CycleDescription	Information about the cycles in the model		default
FitStatistics	Fit statistics based on the one-step-ahead predictions		default
FitSummary	Likelihood-based fit statistics		default
OutlierSummary	Summary table of the detected outliers		default
SeasonDescription	Information about the seasonals in the model		default
SeasonHarmonics	Summary of harmonics in a trigonometric seasonal component	SEASON	PRINT=HARMONICS
SplineSeasonDescription	Information about the spline-seasonals in the model		default
TrendInformation	Summary information of the level and slope components		default
Tables Related to Filtered Component Estimates			
FilteredAutoReg	Filtered estimate of an autoreg component	AUTOREG	PRINT=FILTER
FilteredBlockSeason	Filtered estimate of a block seasonal component	BLOCKSEASON	PRINT=FILTER
FilteredCycle	Filtered estimate of a cycle component	CYCLE	PRINT=FILTER
FilteredIrregular	Filtered estimate of the irregular component	IRREGULAR	PRINT=FILTER
FilteredLevel	Filtered estimate of the level component	LEVEL	PRINT=FILTER
FilteredRandomReg	Filtered estimate of the time-varying random-regression coefficient	RANDOMREG	PRINT=FILTER

Table 31.2 *continued*

ODS Table Name	Description	Statement	Option
FilteredSeason	Filtered estimate of a seasonal component	SEASON	PRINT=FILTER
FilteredSlope	Filtered estimate of the slope component	SLOPE	PRINT=FILTER
FilteredSplineReg	Filtered estimate of the time-varying spline-regression coefficient	SPLINEREG	PRINT=FILTER
FilteredSplineSeason	Filtered estimate of a spline-seasonal component	SPLINESEASON	PRINT=FILTER
Tables Related to Smoothed Component Estimates			
SmoothedAutoReg	Smoothed estimate of an autoreg component	AUTOREG	PRINT=SMOOTH

Tables Related to Series Decomposition and Forecasting			
FilteredAllExceptIrreg	Filtered estimate of sum of all components except the irregular component	FORECAST	PRINT=FDECOMP
FilteredTrend	Filtered estimate of trend	FORECAST	PRINT= FDECOMP
FilteredTrendReg	Filtered estimate of trend plus regression	FORECAST	PRINT=FDECOMP
FilteredTrendRegCyc	Filtered estimate of trend plus regression plus cycles and autoreg	FORECAST	PRINT=FDECOMP

Table 31.2 *continued*

ODS Table Name	Description	Statement	Option
Forecasts	Dependent series forecasts		default
PostSamplePrediction	Forecasting performance in the holdout period	FORECAST	BACK=
SmoothedAllExceptIrreg	Smoothed estimate of sum of all components except the irregular component	FORECAST	PRINT=DECOMP
SmoothedTrend	Smoothed estimate of trend	FORECAST	PRINT= DECOMP
SmoothedTrendReg	Smoothed estimate of trend plus regression	FORECAST	PRINT=DECOMP
SmoothedTrendRegCyc	Smoothed estimate of trend plus regression plus cycles and autoreg	FORECAST	PRINT=DECOMP

NOTE: The tables are related to a single series within a BY group. In the case of models that contain multiple cycles, seasonal components, or block seasonal components, the corresponding component estimate tables are sequentially numbered. For example, if a model contains two cycles and a seasonal component and the PRINT=SMOOTH option is used for each of them, the ODS tables containing the smoothed estimates will be named SmoothedCycle1, SmoothedCycle2, and SmoothedSeason. Note that the seasonal table is not numbered because there is only one seasonal component.

ODS Graph Names

To request graphics with PROC UCM, you must first enable ODS Graphics by specifying the **ODS GRAPHICS ON;** statement. See Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*), for more information. You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC UCM generates are listed in Table 31.3, along with the required statements and options.

Table 31.3 ODS Graphics Produced by PROC UCM

ODS Graph Name	Description	Statement	Option

SmoothedTrendRegCycVarPlot	Plot of standard error of smoothed trend, cycles, and regression effects	FORECAST	PLOT= DECOMPVAR

OUTFOR= Data Set

You can use the `OUTFOR=` option in the `FORECAST` statement to store the series and component forecasts produced by the procedure. This data set contains the following columns:

- the BY variables
- the ID variable. If an ID variable is not specified, then a numerical variable, `_ID_`, is created that contains the observation numbers from the input data set.
- the dependent series and the predictor series
- `FORECAST`, a numerical variable containing the one-step-ahead predicted values and the multistep forecasts
- `RESIDUAL`, a numerical variable containing the difference between the actual and forecast values

- STD, a numerical variable containing the standard error of prediction
- LCL and UCL, numerical variables containing the lower and upper forecast confidence limits
- S_SERIES and VS_SERIES, numerical variables containing the smoothed values of the dependent series and their variances
- S_IRREG and VS_IRREG, numerical variables containing the smoothed values of the irregular component and their variances. These variables are present only if the model has an irregular component.
- F_LEVEL, VF_LEVEL, S_LEVEL, and VS_LEVEL, numerical variables containing the filtered and smoothed values of the level component and the respective variances. These variables are present only if the model has a level component.
- F_SLOPE, VF_SLOPE, S_SLOPE, and VS_SLOPE, numerical variables containing the filtered and smoothed values of the slope component and the respective variances. These variables are present only if the model has a slope component.
- F_AUTOREG, VF_AUTOREG, S_AUTOREG, and VS_AUTOREG, numerical variables containing the filtered and smoothed values of the autoreg component and the respective variances. These variables are present only if the model has an autoreg component.
- F_CYCLE, VF_CYCLE, S_CYCLE, and VS_CYCLE, numerical variables containing the filtered and smoothed values of the cycle component and the respective variances. If there are multiple cycles in the model, these variables are sequentially numbered as F_CYCLE1, F_CYCLE2, etc. These variables are present only if the model has at least one cycle component.
- F_SEASON, VF_SEASON, S_SEASON, and VS_SEASON, numerical variables containing the filtered and smoothed values of the season component and the respective variances. If there are multiple seasons in the model, these variables are sequentially numbered as F_SEASON1, F_SEASON2, etc. These variables are present only if the model has at least one season component.
- F_BLKSEAS, VF_BLKSEAS, S_BLKSEAS, and VS_BLKSEAS, numerical variables containing the filtered and smoothed values of the blockseason component and the respective variances. If there are multiple block seasons in the model, these variables are sequentially numbered as F_BLKSEAS1, F_BLKSEAS2, etc.
- F_SPLSEAS, VF_SPLSEAS, S_SPLSEAS, and VS_SPLSEAS, numerical variables containing the filtered and smoothed values of the splinesseason component and the respective variances. If there are multiple spline seasons in the model, these variables are sequentially numbered as F_SPLSEAS1, F_SPLSEAS2, etc. These variables are present only if the model has at least one splinesseason component.
- Filtered and smoothed estimates, and their variances, of the time-varying regression coefficients of the variables specified in the RANDOMREG and SPLINEREG statements. A variable is not included if its coefficient is time-invariant, that is, if the associated disturbance variance is zero.

- S_TREG and VS_TREG, numerical variables containing the smoothed values of level plus regression component and their variances. These variables are present only if the model has at least one predictor variable or has dependent lags.
- S_TREGCYC and VS_TREGCYC, numerical variables containing the smoothed values of level plus regression plus cycle component and their variances. These variables are present only if the model has at least one cycle or an autoreg component.
- S_NOIRREG and VS_NOIRREG, numerical variables containing the smoothed values of the sum of all components except the irregular component and their variances. These variables are present only if the model has at least one seasonal or block seasonal component.

OUTEST= Data Set

You can use the OUTEST= option in the ESTIMATE statement to store the model parameters and the related estimation details. This data set contains the following columns:

- the BY variables
- COMPONENT, a character variable containing the name of the component corresponding to the parameter being described
- PARAMETER, a character variable containing the parameter name
- TYPE, a character variable indicating whether the parameter value was fixed by the user or estimated
- _STATUS_, a character variable indicating whether the parameter estimation process converged or failed or there was an error of some other kind
- ESTIMATE, a numerical variable containing the parameter estimate
- STD, a numerical variable containing the standard error of the parameter estimate. This has a missing value if the parameter value is fixed.
- TVALUE, a numerical variable containing the t -statistic. This has a missing value if the parameter value is fixed.
- PVALUE, a numerical variable containing the p -value. This has a missing value if the parameter value is fixed.

Statistics of Fit

This section explains the goodness-of-fit statistics reported to measure how well the specified model fits the data.

First the various statistics of fit that are computed using the prediction errors, $y_t - \hat{y}_t$, are considered. In these formulas, n is the number of nonmissing prediction errors and k is the number of fitted parameters in the model. Moreover, the sum of squared errors, $SSE = \sum (y_t - \hat{y}_t)^2$, and the total sum of squares for the series corrected for the mean, $SST = \sum (y_t - \bar{y})^2$, where \bar{y} is the series mean, and the sums are over all the nonmissing prediction errors.

Mean Squared Error

The mean squared prediction error, $MSE = \frac{1}{n}SSE$

Root Mean Squared Error

The root mean square error, $RMSE = \sqrt{MSE}$

Mean Absolute Percent Error

The mean absolute percent prediction error, $MAPE = \frac{100}{n} \sum_{t=1}^n |(y_t - \hat{y}_t)/y_t|$.

The summation ignores observations where $y_t = 0$.

R-square

The R-square statistic, $R^2 = 1 - SSE/SST$.

If the model fits the series badly, the model error sum of squares, SSE , might be larger than SST and the R-square statistic will be negative.

Adjusted R-square

The adjusted R-square statistic, $1 - (\frac{n-1}{n-k})(1 - R^2)$

Amemiya's Adjusted R-square

Amemiya's adjusted R-square, $1 - (\frac{n+k}{n-k})(1 - R^2)$

Random Walk R-square

The random walk R-square statistic (Harvey's R-square statistic that uses the random walk model for comparison), $1 - (\frac{n-1}{n})SSE/RWSSE$, where $RWSSE = \sum_{t=2}^n (y_t - y_{t-1} - \mu)^2$, and $\mu = \frac{1}{n-1} \sum_{t=2}^n (y_t - y_{t-1})$

Maximum Percent Error

The largest percent prediction error, $100 \max((y_t - \hat{y}_t)/y_t)$. In this computation the observations where $y_t = 0$ are ignored.

The likelihood-based fit statistics are reported separately (see the section “The UCMs as State Space Models” on page 1979). They include the full log likelihood (L_∞), the diffuse part of the log likelihood, the normalized residual sum of squares, and several information criteria: AIC, AICC, HQIC, BIC, and CAIC. Let q denote the number of estimated parameters, n be the number of nonmissing measurements in the estimation span, and d be the number of diffuse elements in the initial state vector that are successfully initialized during the Kalman filtering process. Moreover, let $n^* = (n - d)$. The reported information criteria, all in smaller-is-better form, are described in Table 31.4:

Table 31.4 Information Criteria

Criterion	Formula	Reference
AIC	$-2L_\infty + 2q$	Akaike (1974)
AICC	$-2L_\infty + 2qn^*/(n^* - q - 1)$	Hurvich and Tsai (1989)
HQIC	$-2L_\infty + 2q \log \log(n^*)$	Burnham and Anderson (1998)
BIC	$-2L_\infty + q \log(n^*)$	Hannan and Quinn (1979)
		Schwarz (1978)

Table 31.4 *continued*

Criterion	Formula	Reference
CAIC	$-2L_{\infty} + q(\log(n^*) + 1)$	Bozdogan (1987)

Examples: UCM Procedure

Example 31.1: The Airline Series Revisited

The series in this example, the monthly airline passenger series, has already been discussed earlier; see the section “A Seasonal Series with Linear Trend” on page 1935. Recall that the series consists of monthly numbers of international airline travelers (from January 1949 to December 1960). Here additional output features of the UCM procedure are illustrated, such as how to use the ESTIMATE and FORECAST statements to limit the span of the data used in parameter estimation and forecasting. The following statements fit a BSM to the logarithm of the airline passenger numbers. The disturbance variance for the slope component is held fixed at value 0; that is, the trend is locally linear with constant slope. In order to evaluate the performance of the fitted model on observed data, some of the observed data are withheld during parameter estimation and forecast computations. The observations in the last two years, years 1959 and 1960, are not used in parameter estimation, while the observations in the last year, year 1960, are not used in the forecasting computations. This is done using the BACK= option in the ESTIMATE and FORECAST statements. In addition, a panel of residual diagnostic plots is obtained using the PLOT= PANEL option in the ESTIMATE statement.

```

data seriesG;
  set sashelp.air;
  logair = log(air);
run;

ods graphics on;
proc ucm data = seriesG;
  id date interval = month;
  model logair;
  irregular;
  level;
  slope var = 0 noest;
  season length = 12 type=trig;
  estimate back=24 plot=panel;
  forecast back=12 lead=24 print=forecasts;
run;

```

The following tables display the summary of data used in estimation and forecasting (Output 31.1.1 and Output 31.1.2). These tables provide simple summary statistics for the estimation and forecast spans; they include useful information such as the beginning and ending dates of the span, the number of nonmissing values, etc.

Output 31.1.1 Observation Span Used in Parameter Estimation (partial output)

Variable	Type	First	Last	Nobs	Mean
logair	Dependent	JAN1949	DEC1958	120	5.43035

Output 31.1.2 Observation Span Used in Forecasting (partial output)

Variable	Type	First	Last	Nobs	Mean
logair	Dependent	JAN1949	DEC1959	132	5.48654

The following tables display the fixed parameters in the model, the preliminary estimates of the free parameters, and the final estimates of the free parameters (Output 31.1.3, Output 31.1.4, and Output 31.1.5).

Output 31.1.3 Fixed Parameters in the Model

The UCM Procedure		
Fixed Parameters in the Model		
Component	Parameter	Value
Slope	Error Variance	0

Output 31.1.4 Starting Values for the Parameters to Be Estimated

Preliminary Estimates of the Free Parameters		
Component	Parameter	Estimate
Irregular	Error Variance	6.64120
Level	Error Variance	2.49045
Season	Error Variance	1.26676

Output 31.1.5 Maximum Likelihood Estimates of the Free Parameters

Final Estimates of the Free Parameters					
Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > t
Irregular	Error Variance	0.00018686	0.0001212	1.54	0.1233
Level	Error Variance	0.00040314	0.0001566	2.57	0.0100
Season	Error Variance	0.00000350	1.66319E-6	2.10	0.0354

Two types of goodness-of-fit statistics are reported after a model is fit to the series (see [Output 31.1.6](#) and [Output 31.1.7](#)). The first type is the likelihood-based goodness-of-fit statistics, which include the full likelihood of the data, the diffuse portion of the likelihood (see the section “[Details: UCM Procedure](#)” on page 1973), and the information criteria. The second type of statistics is based on the raw residuals, residual = observed – predicted. If the model is nonstationary, then one-step-ahead predictions are not available for some initial observations, and the number of values used in computing these fit statistics will be different from those used in computing the likelihood-based test statistics.

Output 31.1.6 Likelihood-Based Fit Statistics for the Airline Data

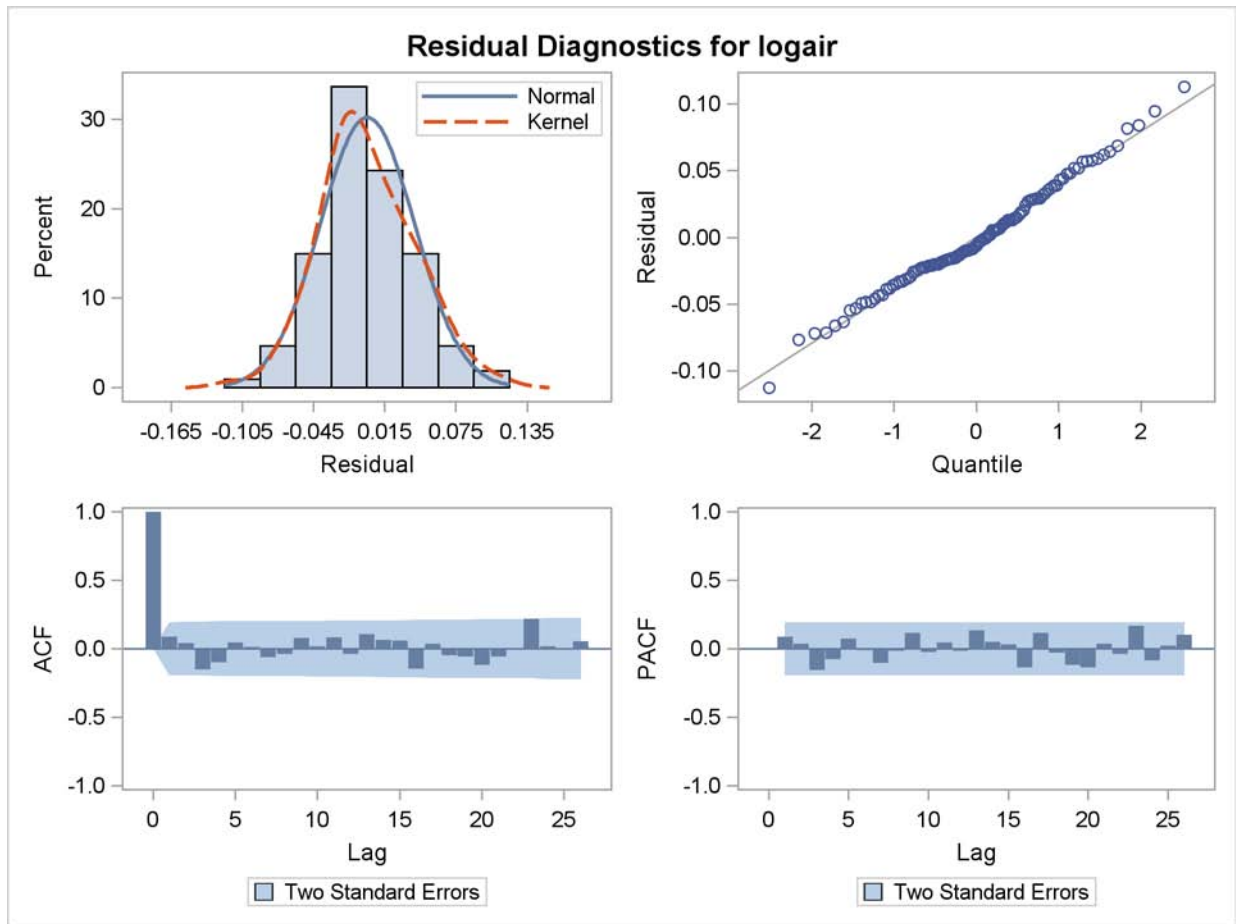

Likelihood Based Fit Statistics	
Statistic	Value
Full Log Likelihood	180.63
Diffuse Part of Log Likelihood	-13.93
Non-Missing Observations Used	120
Estimated Parameters	3
Initialized Diffuse State Elements	13
Normalized Residual Sum of Squares	107
AIC (smaller is better)	-355.3
BIC (smaller is better)	-347.2
AICC (smaller is better)	-355
HQIC (smaller is better)	-352
CAIC (smaller is better)	-344.2

Output 31.1.7 Residuals-Based Fit Statistics for the Airline Data

Fit Statistics Based on Residuals	
Mean Squared Error	0.00156
Root Mean Squared Error	0.03944
Mean Absolute Percentage Error	0.57677
Maximum Percent Error	2.19396
R-Square	0.98705
Adjusted R-Square	0.98680
Random Walk R-Square	0.86370
Amemiya's Adjusted R-Square	0.98630
Number of non-missing residuals used for computing the fit statistics = 107	

The diagnostic plots based on the one-step-ahead residuals are shown in [Output 31.1.8](#). The residual histogram and the Q-Q plot show no reasons to question the approximate normality of the residual distribution. The remaining plots check for the *whiteness* of the residuals. The sample correlation plots, the autocorrelation function (ACF) and the partial autocorrelation function (PACF), also do not show any significant violations of the whiteness of the residuals. Therefore, on the whole, the model seems to fit the data well.

Output 31.1.8 Residual Diagnostics for the Airline Series Using a BSM

The forecasts are given in [Output 31.1.9](#). In order to save the space,

the upper and lower confidence limit columns are dropped from the output, and only the rows corresponding to the year 1960 are shown. Recall that the actual measurements in the years 1959 and 1960 were withheld during the parameter estimation, and the ones in 1960 were not used in the forecast computations.

Output 31.1.9 Forecasts for the Airline Data

Obs	date	Forecast	StdErr	logair	Residual
133	JAN60	6.050	0.038	6.033	-0.017
134	FEB60	5.996	0.044	5.969	-0.027
135	MAR60	6.156	0.049	6.038	-0.118
136	APR60	6.124	0.053	6.133	0.010

143	NOV60	6.015	0.075	5.966	-0.049
144	DEC60	6.121	0.077	6.068	-0.053

The figure **Output 31.1.10** shows the forecast plot. The forecasts in the year 1960 show that the model predictions were quite good.

Output 31.1.10 Forecast Plot of the Airline Series Using a BSM

Example 31.2: Variable Star Data

The series in this example is studied in detail in Bloomfield (2000). This series consists of brightness measurements (magnitude) of a variable star taken at midnight for 600 consecutive days. The data can be downloaded from a time series archive maintained by the University of York, England (<http://www.york.ac.uk/depts/math/data/ts/welcome.htm> (series number 26)). The following DATA step statements read the data in a SAS data set.

```
data star;
  input magnitude @@;
  day = _n_;
datalines;
 25 28 31 32 33 33 32 31 28 25 22 18
 14 10 7 4 2 0 0 0 2 4 8 11
 15 19 23 26 29 32 33 34 33 32 30 27
 24 20 17 13 10 7 5 3 3 3 4 5
 7 10 13 16 19 22 24 26 27 28 29 28
 27 25 24 21 19 17 15 13 12 11 11 10

  ... more lines ...
```

The following statements use the TIMESERIES procedure to get a timeseries plot of the series (see Output 31.2.1).

```
ods graphics on;
proc timeseries data=star plot=series;
  var magnitude;
run;
```

Output 31.2.1 Plot of Star Brightness on Successive Days

The plot clearly shows the cyclic nature of the series. Bloomfield shows that the series is very well explained by a model that includes two deterministic cycles that have periods 29.0003 and 24.0001 days, a constant term, and a simple error term. He also mentions the difficulty involved in estimating the periods from the data (see Bloomfield 2000, Chapter 3). In his case the cycle periods are estimated by least squares, and the sum of squares surface has multiple local optima and ridges. The following statements show how to use the UCM procedure to fit this two-cycle model to the series. The constant term in the model is specified by holding the variance parameter of the level component to zero.

```
proc ucm data=star;
  model magnitude;
  irregular;
  level var=0 noest;
  cycle;
  cycle;
  estimate;
run;
```

The final parameter estimates and the goodness-of-fit statistics are shown in [Output 31.2.2](#) and [Output 31.2.3](#), respectively. The model fit appears to be good.

Output 31.2.2 Two-Cycle Model: Parameter Estimates

The UCM Procedure					
Final Estimates of the Free Parameters					
Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > t
Irregular	Error Variance	0.09257	0.0053845	17.19	<.0001
Cycle_1	Damping Factor	1.00000	1.81175E-7	5519514	<.0001
Cycle_1	Period	29.00036	0.0022709	12770.4	<.0001
Cycle_1	Error Variance	0.00000882	5.27213E-6	1.67	0.0944
Cycle_2	Damping Factor	1.00000	2.11939E-7	4718334	<.0001
Cycle_2	Period	24.00011	0.0019128	12547.2	<.0001
Cycle_2	Error Variance	0.00000535	3.56374E-6	1.50	0.1330

Output 31.2.3 Two-Cycle Model: Goodness of Fit

Fit Statistics Based on Residuals	
Mean Squared Error	0.12072
Root Mean Squared Error	0.34745
Mean Absolute Percentage Error	2.65141
Maximum Percent Error	36.38991
R-Square	0.99850
Adjusted R-Square	0.99849
Random Walk R-Square	0.97281
Amemiya's Adjusted R-Square	0.99847
Number of non-missing residuals used for computing the fit statistics = 599	

A summary of the cycles in the model is given in [Output 31.2.4](#).

Output 31.2.4 Two-Cycle Model: Summary

Name	Type	period	Rho	ErrorVar
Cycle_1	Stationary	29.00036	1.00000	0.00000882
Cycle_2	Stationary	24.00011	1.00000	0.00000535

Note that the estimated periods are the same as in Bloomfield's model, the damping factors are nearly equal to 1.0, and the disturbance variances are very close to zero, implying persistent deterministic cycles. In fact, this model is identical to Bloomfield's model.

Example 31.3: Modeling Long Seasonal Patterns

This example illustrates some of the techniques you can use to model long seasonal patterns in a series. If the seasonal pattern is of moderate length and the underlying dynamics are simple, then it is easily modeled by using the basic settings of the SEASON statement and these additional techniques are not needed. However, if the seasonal pattern has a long season length and/or has a complex stochastic dynamics, then the techniques discussed here can be useful. You can obtain parsimonious models for a long seasonal pattern by using an appropriate subset of trigonometric harmonics, or by using a suitable spline function, or by using a block-season pattern in combination with a seasonal component of much smaller length. You can also vary the disturbance variances of the subcomponents that combine to form the seasonal component.

The time series used in this example consists of number of calls received per shift at a call center. Each shift is six hours long, and the first shift of the day begins at midnight, resulting in four shifts per day. The observations are available from December 15, 1999, to April 30, 2000. This series is seasonal with season length 28, which is moderate, and in fact there is no particular need to use pattern approximation techniques in this case. However, it is adequate for demonstration purposes. The plan of this example is as follows. First an initial model with a full seasonal component is created. This model is used as a baseline for comparing alternate models created by the techniques that are being illustrated. In practice any candidate model is first checked for adequacy by using various diagnostic procedures. In this illustration the main focus is on the different ways a long seasonal pattern can be modeled and no model diagnostics are done for the models being entertained. The alternate models are compared by using the sum of absolute prediction errors in the holdout region.

The following DATA step statements create the input data set used in this example.

```
data callCenter;
  input calls @@;
  label calls= "Number of Calls Received in a 6 Hour Shift";
  start = '15dec99:00:00'dt;
  datetime = INTNX( 'dthour6', start, _n_-1 );
  format datetime datetime10.;
datalines;
  18    122    244    128    19    113    230    119    17    112
  219    93    14    73    139    53    11    32    74    56
  15    137    289    153    20    125    227    106    16    101
  ... more lines ...
```

Initial exploration of the series clearly indicates that the series does not show any significant trend, and time of day and day of the week have a significant influence on the number of calls received. These considerations suggest a simple random walk trend model along with a seasonal component of season length 28, the total number of shifts in a week. The following statements specify this model. Note the PRINT=HARMONICS option in the SEASON statement, which produces a table that lists the full set of harmonics contributing to the seasonal along with the significance of their contribution. This table will be useful later in choosing a subset trigonometric model. The BACK=28 and the LEAD=28 specifications in the FORECAST statement create a holdout region of 28 observations.

The sum of absolute prediction errors (SAE) in this holdout region are used to compare the different models.

```
proc ucm data=callCenter;
  id datetime interval=dthour6;
  model calls;
  irregular;
  level;
  season length=28 type=trig
    print=(harmonics);
  estimate back=28;
  forecast back=28 lead=28;
run;
```

The forecasting performance of this model in the holdout region is shown in [Output 31.3.1](#). The sum of absolute prediction errors $SAE = 516.22$, which appears in the last row of the holdout analysis table.

Output 31.3.1 Predictions in the Holdout Region: Baseline Model

Obs	datetime	Actual	Forecast	Error	SAE
525	24APR00:00	12	-4.004	16.004	16.004

551	30APR00:12	66	49.524	16.476	495.287
552	30APR00:18	61	40.071	20.929	516.216

Now that a baseline model is created, the exploration for alternate models can begin. The review of the harmonic table in [Output 31.3.2](#) shows that all but the last three harmonics are significant, and deleting any of them to form a subset trigonometric seasonal component will lead to a poorer model. The last

three harmonics, 12th, 13th and 14th, with periods of 2.333, 2.15 and 2.0, respectively, do appear to be possible choices for deletion. Note that the disturbance variance of the seasonal component is not very insignificant (see [Output 31.3.3](#)); therefore the seasonal component is stochastic and the preceding logic, which is based on the final state estimate, provides only a rough guideline.

Output 31.3.2 Harmonic Analysis of the Season: Initial Model

The UCM Procedure						
Harmonic Analysis of Trigonometric Seasons (Based on the Final State)						
Name	Season Length	Harmonic	Period	Chi-Square	DF	Pr > ChiSq
Season	28	1	28.00000	234.19	2	<.0001
Season	28	2	14.00000	264.19	2	<.0001
Season	28	3	9.33333	95.65	2	<.0001
Season	28	4	7.00000	105.64	2	<.0001
Season	28	5	5.60000	146.74	2	<.0001
Season	28	6	4.66667	121.93	2	<.0001

Season	28	14	2.00000	2.33	1	0.1272

Output 31.3.3 Parameter Estimates: Initial Model

Final Estimates of the Free Parameters					
Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > t
Irregular	Error Variance	92.14591	13.10986	7.03	<.0001
Level	Error Variance	44.83595	10.65465	4.21	<.0001
Season	Error Variance	0.01250	0.0065153	1.92	0.0551

The following statements fit a subset trigonometric model formed by dropping the last three harmonics by specifying the DROPH= option in the SEASON statement:

```
proc ucm data=callCenter;
  id datetime interval=dthour6;
  model calls;
  irregular;
  level;
  season length=28 type=trig droph=12 13 14;
  estimate back=28;
  forecast back=28 lead=28;
run;
```

The last row of the holdout region prediction analysis table for the preceding model is shown in [Output 31.3.4](#). It shows that the subset trigonometric model has better prediction performance in the holdout region than the full trigonometric model, its SAE = 471.53 compared to the SAE = 516.22 for the full model.

Output 31.3.4 SAE for the Subset Trigonometric Model

Obs	datetime	Actual	Forecast	Error	SAE
552	30APR00:18	61	40.836	20.164	471.534

The following statements illustrate a spline approximation to this seasonal component. In the spline specification the knot placement is quite important, and usually some experimentation is needed. In the following model the knots are placed at the beginning and the middle of each day. Note that the knots at the beginning and end of the season, 1 and 28 in this case, should not be listed in the knot list because knots are always placed there anyway.

```
proc ucm data=callCenter;
  id datetime interval=dthour6;
  model calls;
  irregular;
  level;
  splineseason length=28
    knots=3 5 7 9 11 13 15 17 19 21 23 25 27
    degree=3;
  estimate back=28;
  forecast back=28 lead=28;
run;
```

The spline season model takes about half the time to fit that the baseline model takes. The last row of the holdout region prediction analysis table for this model is shown in [Output 31.3.5](#), which shows that the spline season model performs even better than the previous two models in the holdout region, its SAE = 313.79 compared to SAE = 471.53 for the previous model.

Output 31.3.5 SAE for the Spline Season Model

Obs	datetime	Actual	Forecast	Error	SAE
552	30APR00:18	61	23.350	37.650	313.792

The following statements illustrate yet another way to approximate a long seasonal component. Here a combination of BLOCKSEASON and SEASON statements results in a seasonal component that is a sum of two seasonal patterns: one seasonal pattern is simply a regular season with season length 4 that captures the *within-day* seasonal pattern, and the other seasonal pattern is a block seasonal pattern that remains constant during the day but varies from day to day within a week. Note the use of NLOPTIONS statement to change the optimization technique during the parameter estimation to DBLDOG, which in this case performs better than the default technique, TRUREG.

```

proc ucm data=callCenter;
  id datetime interval=dthour6;
  model calls;
  irregular;
  level;
  season length=4 type=trig;
  blockseason nblocks=7 blocksize=4
    type=trig;
  estimate back=28;
  forecast back=28 lead=28;
  nloptions tech=dbldog;
run;

```

This model also takes about half the time to fit that the baseline model takes. The last row of the holdout region prediction analysis table for this model is shown in [Output 31.3.6](#), which shows that the block season model does slightly better than the baseline model but not as good as the other two models, its SAE = 508.52 compared to the SAE = 516.22 of the baseline model.

Output 31.3.6 SAE for the Block Season Model

Obs	datetime	Actual	Forecast	Error	SAE
552	30APR00:18	61	39.339	21.661	508.522

This example showed a few different ways to model a long seasonal pattern. It showed that parsimonious models for long seasonal patterns can be useful, and in some cases even more effective than the full model. Moreover, for very long seasonal patterns the high memory requirements and long computing times might make full models impractical.

Example 31.4: Modeling Time-Varying Regression Effects

In April 1979 the Albuquerque Police Department began a special enforcement program aimed at reducing the number of DWI (driving while intoxicated) accidents. The program was administered by a squad of police officers, who used breath alcohol testing (BAT) devices and a van that houses a BAT device (Batmobile). These data were collected by the Division of Governmental Research of the University of New Mexico, under a contract with the National Highway Traffic Safety Administration of the U.S. Department of Transportation, to evaluate the Batmobile program. The first 29 observations are for a control period, and the next 23 observations are for the experimental (Batmobile) period. The data, freely available at <http://lib.stat.cmu.edu/DASL/Datafiles/batdat.html>, consist of two variables: ACC, which represents injuries and fatalities from Wednesday to Saturday nighttime accidents, and FUEL, which represents fuel consumption (millions of gallons) in Albuquerque. The variables are measured quarterly starting from the first quarter of 1972 up to the last quarter of 1984, covering the span of 13 years. The following DATA step statements create the input data set.

```

data bat;
  input ACC FUEL @@;
  batProgram = 0;
  if _n_ > 29 then batProgram = 1;
  date = INTNX( 'qtr', '1jan1972'd, _n_ - 1 );
  format date qtr8.;
datalines;
192    32.592    238    37.250    232    40.032
246    35.852    185    38.226    274    38.711
266    43.139    196    40.434    170    35.898
234    37.111    272    38.944    234    37.717
210    37.861    280    42.524    246    43.965
248    41.976    269    42.918    326    49.789
342    48.454    257    45.056    280    49.385
290    42.524    356    51.224    295    48.562
279    48.167    330    51.362    354    54.646
331    53.398    291    50.584    377    51.320
327    50.810    301    46.272    269    48.664
314    48.122    318    47.483    288    44.732
242    46.143    268    44.129    327    46.258
253    48.230    215    46.459    263    50.686
319    49.681    263    51.029    206    47.236
286    51.717    323    51.824    306    49.380
230    47.961    304    46.039    311    55.683
292    52.263
;

```

There are a number of ways to study these data and the question of the effectiveness of the BAT program. One possibility is to study the *before-after* difference in the injuries and fatalities per million gallons of fuel consumed, by regressing ACC on the FUEL and the dummy variable BATPROGRAM, which is zero before the program began and one while the program is in place. However, it is possible that the effect of the Batmobiles might well be cumulative, because as awareness of the program becomes dispersed, its effectiveness as a deterrent to driving while intoxicated increases. This suggests that the regression coefficient of the BATPROGRAM variable might be *time varying*. The following program fits a model that incorporates these considerations. A seasonal component is included in the model since it is easy to see that the data show strong quarterly seasonality.

```

ods graphics on;
proc ucm data=bat;
  model acc = fuel;
  id date interval=qtr;
  irregular;
  level var=0 noest;
  randomreg batProgram / plot=smooth;
  season length=4 var=0 noest plot=smooth;
  estimate plot=(panel residual);
  forecast plot=forecasts lead=0;
run;

```

The model seems to fit the data adequately. No data are withheld for model validation because the series is relatively short. The plot of the time-varying coefficient of BATPROGRAM is shown in [Output 31.4.1](#). As expected, it shows that the effectiveness of the program increases as awareness

of the program becomes dispersed. The effectiveness eventually seems to level off. The residual diagnostic plots are shown in [Output 31.4.2](#) and [Output 31.4.3](#), the forecast plot is in [Output 31.4.4](#), the goodness-of-fit statistics are in [Output 31.4.5](#), and the parameter estimates are in [Output 31.4.6](#).

Example 31.5: Trend Removal Using the Hodrick-Prescott Filter

Hodrick-Prescott filter (see Hodrick and Prescott (1997)) is a popular tool in macroeconomics for fitting smooth trend to time series. It is well known that the trend computation according to this filter is equivalent to fitting the local linear trend plus irregular model with the level disturbance variance restricted to zero and the slope disturbance variance restricted to be a suitable multiple of the irregular component variance. The multiple used depends on the frequency of the series; for example, for quarterly series the commonly recommended multiple is $1/1600 = 0.000625$. For other intervals there is no consensus, but a frequently suggested value for monthly series is $1/14400$ and the value for an annual series can range from $1/400 = 0.0025$ to $1/7 = 0.15$. The data set considered in this example consists of quarterly GNP values for the United States from 1960 to 1991. In the UCM procedure statements that follow, the presence of the PROFILE option in the ESTIMATE statement implies that the restriction that the disturbance variance of the slope component be fixed at 0.000625 is interpreted differently: it implies that the disturbance variance of the slope component be restricted to be 0.000625 *times* the estimated irregular component variance, as needed for the Hodrick-Prescott filter. The plot of the fitted trend is shown in [Output 31.5.1](#), and the plot of the smoothed irregular component, which corresponds to the detrended series, is given in [Output 31.5.2](#). The detrended series can be further analyzed for business cycles.

```
ods graphics on;
proc ucm data=sashelp.gnp;
  id date interval=qtr;
  model gnp;
  irregular plot=smooth;
  level var=0 noest plot=smooth;
  slope var=0.000625 noest;
  estimate PROFILE;
  forecast plot=(decomp);
run;
```

Output 31.5.1 Smoothed Trend for the GNP Series as per the Hodrick-Prescott Filter

Output 31.5.2 Detrended GNP Series**Example 31.6: Using Splines to Incorporate Nonlinear Effects**

The data in this example are created to mirror the electricity demand and temperature data recorded at a utility company in the midwest region of the United States. The data set (not shown), `utility`, has three variables: `load`, `temp`, and `date`. The `load` column contains the daily electricity demand, the `temp` column has the average daily temperature readings, and the `date` column records the observation date.

The following statements produce a plot, shown in [Output 31.6.1](#), of electricity load versus temperature. Clearly the relationship is smooth but nonlinear: the load generally increases when the temperatures are away from the comfortable sixties.

```
ods graphics on;
proc sgplot data=utility;
  loess x=temp y=load / smooth=0.4;
run;
```

Output 31.6.1 Load versus Temperature Plot

The time series plot of the load (not shown) also shows that, apart from a day-of-the-week seasonal effect, there are no additional easily identifiable patterns in the series. The series has no apparent upward or downward trend. The following statements fit a UCM to the series that takes into account these observations. The particular choice of the model is a result of a little modeling exercise that compared a small number of competing models. The chosen model is adequate but by no means the best possible. The temperature effect is modeled by a deterministic three-degree spline with knots at 30, 40, 50, 60, and 75. The knot locations and the degree were chosen by visual inspection of the plot (Output 31.6.1). An autoreg component is used in place of the simple irregular component, which improved the residual analysis. The last 60 days of data are withheld for out-of-sample forecast evaluation (note the `BACK=` option in both the `ESTIMATE` and `FORECAST` statements). The `OUTLIER` statement is used to increase the number of outliers reported to 10. Since no `CHECKBREAK` option is used in the `LEVEL` statement, only the additive outliers are searched. In this example the use of the `EXTRADIFFUSE=` option in the `ESTIMATE` and `FORECAST` statements is useful for discarding some early one-step-ahead forecasts and residuals with large variance.

```
proc ucm data=utility;
  id date interval=day;
  model load;
  autoreg;
  level plot=smooth;
  splinereg temp knots=30 40 50 65 75 degree=3
    variance=0 noest;
  season length=7 var=0 noest;
  estimate plot=panel back=60
    extradiffuse=50;
  outlier maxnum=10;
  forecast back=60 lead=60
    extradiffuse=50;
run;
```

The parameter estimates are given in [Output 31.6.2](#), and the residual goodness-of-fit statistics are shown in [Output 31.6.3](#). The residual diagnostic plots are shown in [Output 31.6.4](#). The ACF and PACF plots appear satisfactory, but the normality plots, particularly the Q-Q plot, show possible violations. It appears that, at least in part, this nonNormal behavior of the residuals might be attributable to the outliers in the series. The outlier summary table, [Output 31.6.5](#), shows the most likely outlying observations. Notice that most of these outliers are holidays, like July 4th, when the electricity load is lower than usual for that day of the week.

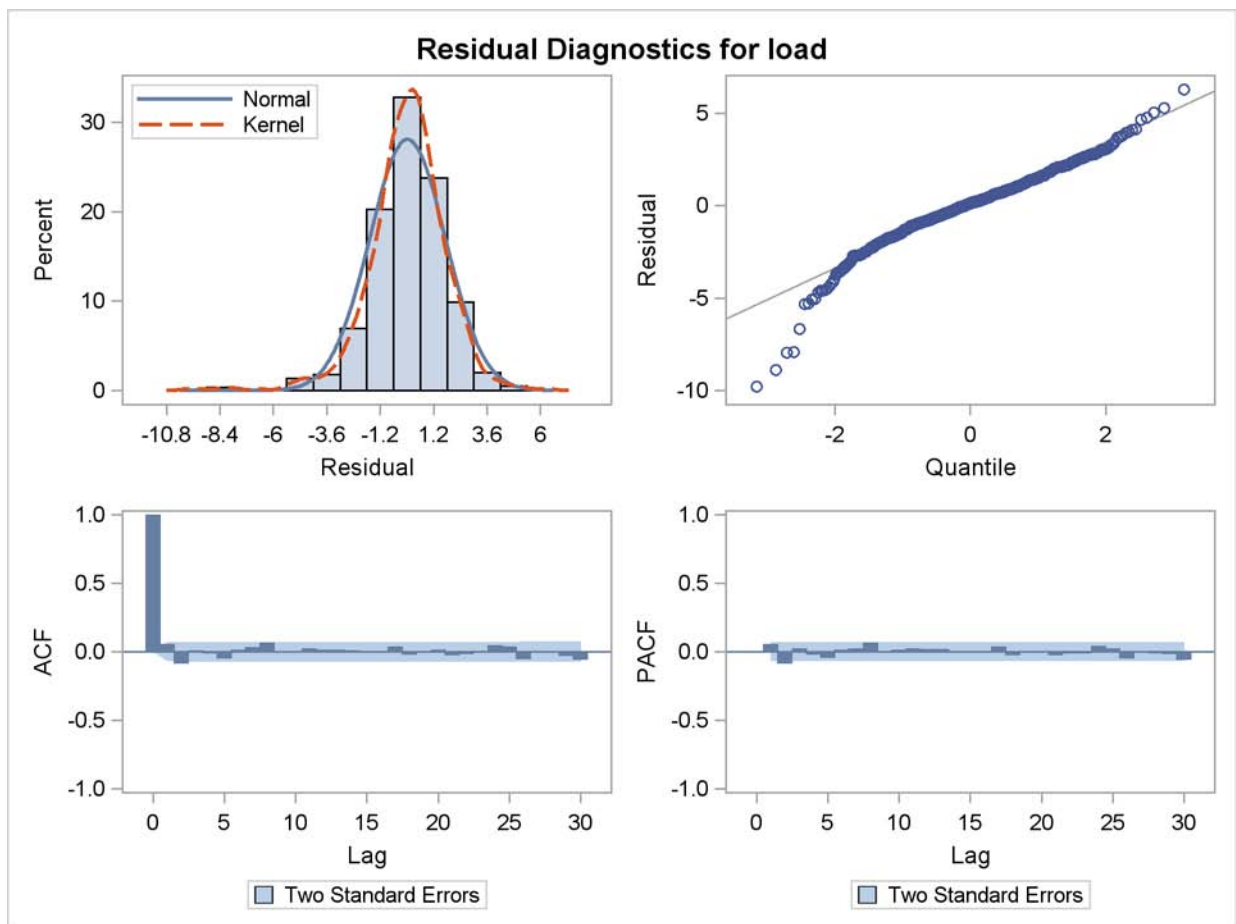

Output 31.6.2 Electricity Load: Parameter Estimates

The UCM Procedure

Output 31.6.6 Electricity Load: Forecast Evaluation of the Withheld Data

Example 31.7: Detection of Level Shift

The series in this example consists of the yearly water level readings of the Nile River recorded at Aswan, Egypt (see Cobb (1978) and de Jong and Penzer (1998)). The readings are from the years 1871 to 1970. The series does not show any apparent trend or any other distinctive patterns; however, there is a shift in the water level starting at the year 1899. This shift could be attributed to the start of construction of a dam near Aswan in that year. A time series plot of this series is given in Output 31.7.1. The following DATA step statements create the input data set.

```
data nile;
  input waterlevel @@;
  year = intnx( 'year', '1jan1871'd, _n_-1 );
  format year year4.;
datalines;
  1120 1160 963 1210 1160 1160 813 1230 1370 1140
  995 935 1110 994 1020 960 1180 799 958 1140
  1100 1210 1150 1250 1260 1220 1030 1100 774 840
  874 694 940 833 701 916 692 1020 1050 969
  831 726 456 824 702 1120 1100 832 764 821
  768 845 864 862 698 845 744 796 1040 759
  781 865 845 944 984 897 822 1010 771 676
  649 846 812 742 801 1040 860 874 848 890
  744 749 838 1050 918 986 797 923 975 815
  1020 906 901 1170 912 746 919 718 714 740
;

ods graphics on;
proc timeseries data=nile plot=series;
  id year interval=year;
  var waterlevel;
run;
```

Output 31.7.1 Nile Water Level

In this situation it is known that a shift in the water level occurred within the span of the series, and its effect can be easily taken into account by including an appropriate indicator variable as a regressor. However, in many situations such prior information is not available, and it is useful to detect such a shift in a data analytic fashion. You can check for breaks in the level by using the **CHECKBREAK** option in the **LEVEL** statement. The following statements fit a simple locally constant level plus error model to the series:

```
proc ucm data=nile;
  id year interval=year;
  model waterlevel;
  irregular;
  level plot=smooth checkbreak;
  estimate;
  forecast plot=decomp;
run;
```

The plot in [Output 31.7.2](#) shows a noticeable drop in the smoothed water level around 1899.

Output 31.7.2 Smoothed Trend without the Shift of 1899

The “Outlier Summary” table in [Output 31.7.3](#) shows the most likely types of breaks and their locations within the series span. The shift of 1899 is easily detected.

Output 31.7.3 Detection of Structural Breaks in the Nile River Level

Outlier Summary						
Obs	year	Break Type	Standard			
			Estimate	Error	Chi-Square	DF Pr > ChiSq
29	1899	Level	-315.73791	97.639753	10.46	1 0.0012

The following statements specify a UCM that models the level of the river as a locally constant series with a shift in the year 1899, represented by a dummy regressor (SHIFT1899):

```
data nile;
  set nile;
  shift1899 = ( year >= '1jan1899'd );
run;
```

```

proc ucm data=nile;
  id year interval=year;
  model waterlevel = shift1899;
  irregular;
  level;
  estimate;
  forecast plot=decomp;
run;

```

The plot in [Output 31.7.4](#) shows the smoothed trend, including the correction due to the shift in the year 1899. Notice the simplicity in the shape of the smoothed curve after the incorporation of the shift information.

Output 31.7.4 Smoothed Trend plus Shift of 1899

Example 31.8: ARIMA Modeling

This example shows how you can use the UCM procedure for ARIMA modeling. The parameter estimates and predictions for ARIMA models obtained by using PROC UCM will be close to those obtained by using PROC ARIMA (in the presence of the ML option in its ESTIMATE statement)

if the model is stationary or if the model is nonstationary and there are no missing values in the data. See Chapter 7, “[The ARIMA Procedure](#),” for additional details about the ARIMA procedure. However, if there are missing values in the data and the model is nonstationary, then the UCM and ARIMA procedures can produce significantly different parameter estimates and predictions. An article by Kohn and Ansley (1986) suggests a statistically sound method of estimation, prediction, and interpolation for nonstationary ARIMA models with missing data. This method is based on an algorithm that is equivalent to the Kalman filtering and smoothing algorithm used in the UCM procedure. The results of an illustrative example in their article are reproduced here using the UCM procedure. In this example an $ARIMA(0,1,1) \times (0,1,1)_{12}$ model is applied to the logarithm of the air series in the `sashelp.air` data set. Four different missing value patterns are considered to highlight different aspects of the problem:

- *Data1*. The full data set of 144 observations.
- *Data2*. The set of 78 observations that omit January through November in each of the last 6 years.
- *Data3*. The data set with the 5 observations July 1949, June, July, and August 1957, and July 1960 missing.
- *Data4*. The data set with all July observations missing and June and August 1957 also missing.

The following DATA steps create these data sets:

```
data Data1;
    set sashelp.air;
    logair = log(air);
run;

data Data2;
    set data1;
    if year(date) >= 1955 and month(date) < 12 then logair = .;
run;

data Data3;
    set data1;
    if (year(date) = 1949 and month(date) = 7) then logair = .;
    if ( year(date) = 1957 and
        (month(date) = 6 or month(date) = 7 or month(date) = 8) )
        then logair = .;
    if (year(date) = 1960 and month(date) = 7) then logair = .;
run;

data Data4;
    set data1;
    if month(date) = 7 then logair = .;
    if year(date) = 1957 and (month(date) = 6 or month(date) = 8)
        then logair = .;
run;
```

The following statements specify the $ARIMA(0, 1, 1) \times (0, 1, 1)_{12}$ model for the `logair` series in the first data set (`Data1`):

```

proc ucm data=Data1;
  id date interval=month;
  model logair;
  irregular q=1 sq=1 s=12;
  deplag lags=(1) (12) phi=1 1 noest;
  estimate outest=est1;
  forecast outfor=for1;
run;

```

Note that the moving average part of the model is specified by using the Q=, SQ=, and S= options in the IRREGULAR statement and the differencing operator, $(1 - B)(1 - B^{12})$, is specified by using the DEPLAG statement. The model does not contain an intercept term; therefore no LEVEL statement is needed. The parameter estimates are saved in a data set EST1 by using the OUTEST= option in the ESTIMATE statement and the forecasts and the component estimates are saved in a data set FOR1 by using the OUTFOR= option in the FORECAST statement. The same analysis is performed on the other three data sets, but is not shown here.

Output 31.8.1 resembles Table 1 in Kohn and Ansley (1986). This table is generated by merging the parameter estimates from the four analyses. Only the moving average parameter estimates and their standard errors are reported. The columns EST1 and STD1 correspond to the estimates for Data1. The parameter estimates and their standard errors for other three data sets are similarly named. Note that the parameter estimates closely match the parameter estimates in the article. However, their standard errors differ slightly. This difference could be the result of different ways of computing the Hessian at the optimum. The white noise error variance estimates are not reported here, but they agree quite closely with those in the article.

Output 31.8.1 Data Sets 1–4: Parameter Estimates and Standard Errors

P A R A M E T E R	e		s		e		s	
	s	t	s	t	s	t	s	t
R	1	1	2	2	3	3	4	4
MA_1	0.402	0.090	0.457	0.121	0.408	0.092	0.431	0.091
SMA_1	0.557	0.073	0.758	0.236	0.566	0.075	0.573	0.074

Output 31.8.2 resembles Table 2 in Kohn and Ansley (1986). It contains forecasts and their standard errors for the four data sets. The numbers are very close to those in the article.

Output 31.8.2 Data Sets 1–4: Forecasts and Standard Errors

DATE	for1	std1	for2	std2	for3	std3	for4	std4
JAN61	6.110	0.037	6.084	0.052	6.110	0.037	6.111	0.037
FEB61	6.054	0.043	6.091	0.058	6.054	0.043	6.055	0.043
MAR61	6.172	0.048	6.247	0.063	6.173	0.048	6.174	0.048
APR61	6.199	0.053	6.205	0.068	6.199	0.053	6.200	0.052
MAY61	6.233	0.057	6.199	0.072	6.232	0.058	6.233	0.056
JUN61	6.369	0.061	6.308	0.076	6.367	0.062	6.368	0.060
JUL61	6.507	0.065	6.409	0.079	6.497	0.067	.	.
AUG61	6.503	0.069	6.414	0.082	6.503	0.069	6.503	0.067

OCT61	6.209	0.075	6.174	0.087	6.209	0.076	6.209	0.074
NOV61	6.063	0.079	6.043	0.089	6.064	0.079	6.064	0.077
DEC61	6.168	0.082	6.174	0.086	6.168	0.082	6.169	0.080

Output 31.8.3 is based on Data2. It resembles Table 3 in Kohn and Ansley (1986). The columns S_SERIES and VS_SERIES in the **OUTFOR=** data set contain the interpolated values of logair and their variances. The estimate column in **Output 31.8.3** reports interpolated values (which are the same as S_SERIES), and the std column reports their standard errors (which are computed as square root of VS_SERIES) for January–November 1957. The actual logair values for these months, which are missing in Data2, are also provided for comparison. The numbers are very close to those in the article.

Output 31.8.3 Data Set 2: Interpolated Values and Standard Errors

DATE	logair	estimate	std
JAN57	5.753	5.733	0.045
FEB57	5.707	5.738	0.049
MAR57	5.875	5.893	0.052
APR57	5.852	5.850	0.054
MAY57	5.872	5.843	0.055
JUN57	6.045	5.951	0.055
JUL57	6.142	6.051	0.055
AUG57	6.146	6.055	0.054
SEP57	6.001	5.938	0.052
OCT57	5.849	5.812	0.049
NOV57	5.720	5.680	0.045

Output 31.8.4 resembles Table 4 in Kohn and Ansley (1986). These numbers are based on Data3, and they also are very close to those in the article.

Output 31.8.4 Data Set 3: Interpolated Values and Standard Errors

DATE	logair	estimate	std
JUL49	4.997	5.013	0.031
JUN57	6.045	6.024	0.030
JUL57	6.142	6.147	0.031
AUG57	6.146	6.148	0.030
JUL60	6.433	6.409	0.031

Output 31.8.5 resembles Table 5 in Kohn and Ansley (1986). As before, the numbers are very close to those in the article.

Output 31.8.5 Data Set 4: Interpolated Values and Standard Errors

DATE	logair	estimate	std
JUN57	6.045	6.023	0.030
AUG57	6.146	6.147	0.030

The similarity between the outputs in this example and the results shown in Kohn and Ansley (1986) demonstrate that PROC UCM can be effectively used for nonstationary ARIMA models with missing data.

Overview: VARMAX Procedure

Given a multivariate time series, the VARMAX procedure estimates the model parameters and generates forecasts associated with vector autoregressive moving-average processes with exogenous regressors (VARMAX) models. Often, economic or financial variables are not only contemporaneously correlated to each other, they are also correlated to each other's past values. The VARMAX procedure can be used to model these types of time relationships. In many economic and financial applications, the variables of interest (dependent, response, or endogenous variables) are influenced by variables external to the system under consideration (independent, input, predictor, regressor, or exogenous variables). The VARMAX procedure enables you to model the dynamic relationship both between the dependent variables and also between the dependent and independent variables.

VARMAX models are defined in terms of the orders of the autoregressive or moving-average process (or both). When you use the VARMAX procedure, these orders can be specified by options or they can be automatically determined. Criteria for automatically determining these orders include the following:

- Akaike information criterion (AIC)
- corrected AIC (AICC)
- Hannan-Quinn (HQ) criterion
- final prediction error (FPE)

- Schwarz Bayesian criterion (SBC), also known as Bayesian information criterion (BIC)

If you do not want to use the automatic order selection, the VARMAX procedure provides autoregressive order identification aids:

- partial cross-correlations
- Yule-Walker estimates
- partial autoregressive coefficients
- partial canonical correlations

For situations where the stationarity of the time series is in question, the VARMAX procedure provides tests to aid in determining the presence of unit roots and cointegration. These tests include the following:

- Dickey-Fuller tests
- Johansen cointegration test for nonstationary vector processes of integrated order one
- Stock-Watson common trends test for the possibility of cointegration among nonstationary vector processes of integrated order one
- Johansen cointegration test for nonstationary vector processes of integrated order two

For stationary vector times series (or nonstationary series made stationary by appropriate differencing), the VARMAX procedure provides for vector autoregressive and moving-average (VARMA) and Bayesian vector autoregressive (BVAR) models. To cope with the problem of high dimensionality in the parameters of the VAR model, the VARMAX procedure provides both vector error correction model (VECM) and Bayesian vector error correction model (BVECM). Bayesian models are used when prior information about the model parameters is available. The VARMAX procedure also allows independent (exogenous) variables with their distributed lags to influence dependent (endogenous) variables in various models such as VARMAX, BVARX, VECMX, and BVECMX models.

Forecasting is one of the main objectives of multivariate time series analysis. After successfully fitting the VARMAX, BVARX, VECMX, and BVECMX models, the VARMAX procedure computes predicted values based on the parameter estimates and the past values of the vector time series.

The model parameter estimation methods are the following:

- least squares (LS)
- maximum likelihood (ML)

The VARMAX procedure provides various hypothesis tests of long-run effects and adjustment coefficients by using the likelihood ratio test based on Johansen cointegration analysis. The VARMAX procedure offers the likelihood ratio test of the weak exogeneity for each variable.

After fitting the model parameters, the VARMAX procedure provides for model checks and residual analysis by using the following tests:

- Durbin-Watson (DW) statistics
- F test for autoregressive conditional heteroscedastic (ARCH) disturbance
- F test for AR disturbance
- Jarque-Bera normality test
- Portmanteau test

The VARMAX procedure supports several modeling features, including the following:

- seasonal deterministic terms
- subset models
- multiple regression with distributed lags
- dead-start model that does not have present values of the exogenous variables
- GARCH-type multivariate conditional heteroscedasticity models

The VARMAX procedure provides a Granger causality test to determine the Granger-causal relationships between two distinct groups of variables. It also provides the following:

- infinite order AR representation
- impulse response function (or infinite order MA representation)
- decomposition of the predicted error covariances
- roots of the characteristic functions for both the AR and MA parts to evaluate the proximity of the roots to the unit circle
- contemporaneous relationships among the components of the vector time series

Getting Started: VARMAX Procedure

This section outlines the use of the VARMAX procedure and gives five different examples of the kinds of models supported.

Vector Autoregressive Process

Let $\mathbf{y}_t = (y_{1t}, \dots, y_{kt})'$, $t = 1, 2, \dots$, denote a k -dimensional time series vector of random variables of interest. The p th-order VAR process is written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \Phi_1 \mathbf{y}_{t-1} + \dots + \Phi_p \mathbf{y}_{t-p} + \boldsymbol{\epsilon}_t$$

where the $\boldsymbol{\epsilon}_t$ is a vector white noise process with $\boldsymbol{\epsilon}_t = (\epsilon_{1t}, \dots, \epsilon_{kt})'$ such that $E(\boldsymbol{\epsilon}_t) = 0$, $E(\boldsymbol{\epsilon}_t \boldsymbol{\epsilon}_t') = \Sigma$, and $E(\boldsymbol{\epsilon}_t \boldsymbol{\epsilon}_s') = 0$ for $t \neq s$; $\boldsymbol{\delta} = (\delta_1, \dots, \delta_k)'$ is a constant vector and Φ_i is a $k \times k$ matrix.

Analyzing and modeling the series jointly enables you to understand the dynamic relationships over time among the series and to improve the accuracy of forecasts for individual series by using the additional information available from the related series and their forecasts.

Example of Vector Autoregressive Model

Consider the first-order stationary bivariate vector autoregressive model

$$\mathbf{y}_t = \begin{pmatrix} 1.2 & -0.5 \\ 0.6 & 0.3 \end{pmatrix} \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t, \quad \text{with } \Sigma = \begin{pmatrix} 1.0 & 0.5 \\ 0.5 & 1.25 \end{pmatrix}$$

The following IML procedure statements simulate a bivariate vector time series from this model to provide test data for the VARMAX procedure:

```
proc iml;
  sig = {1.0 0.5, 0.5 1.25};
  phi = {1.2 -0.5, 0.6 0.3};
  /* simulate the vector time series */
  call varmasim(y,phi) sigma = sig n = 100 seed = 34657;
  cn = {'y1' 'y2'};
  create simull from y[colname=cn];
  append from y;
quit;
```

The following statements plot the simulated vector time series \mathbf{y}_t shown in [Figure 32.1](#):

```
data simull;
  set simull;
  date = intnx( 'year', '01jan1900'd, _n_-1 );
  format date year4.;
run;

proc timeseries data=simull vectorplot=series;
  id date interval=year;
  var y1 y2;
run;
```

Figure 32.1 Plot of Generated Data Process

The following statements fit a VAR(1) model to the simulated data. First, you specify the input data set in the PROC VARMAX statement. Then, you use the MODEL statement to designate the dependent variables, y_1 and y_2 . To estimate a VAR model with mean zero, you specify the order of the autoregressive model with the P= option and the NOINT option. The MODEL statement fits the model to the data and prints parameter estimates and their significance. The PRINT=ESTIMATES option prints the matrix form of parameter estimates, and the PRINT=DIAGNOSE option prints various diagnostic tests. The LAGMAX=3 option is used to print the output for the residual diagnostic checks.

To output the forecasts to a data set, you specify the OUTPUT statement with the OUT= option. If you want to forecast five steps ahead, you use the LEAD=5 option. The ID statement specifies the yearly interval between observations and provides the Time column in the forecast output.

The VARMAX procedure output is shown in Figure 32.2 through Figure 32.10.

```

/*--- Vector Autoregressive Model ---*/

proc varmax data=simul1;
  id date interval=year;
  model y1 y2 / p=1 noint lagmax=3
           print=(estimates diagnose);
  output out=for lead=5;
run;

```

Figure 32.2 Descriptive Statistics

The VARMAX Procedure						
		Number of Observations	100			
		Number of Pairwise Missing	0			
Simple Summary Statistics						
Variable	Type	N	Mean	Standard Deviation	Min	Max
y1	Dependent	100	-0.21653	2.78210	-4.75826	8.37032
y2	Dependent	100	0.16905	2.58184	-6.04718	9.58487

The VARMAX procedure first displays descriptive statistics. The Type column specifies that the variables are dependent variables. The column N stands for the number of nonmissing observations.

Figure 32.3 shows the type and the estimation method of the fitted model for the simulated data. It also shows the AR coefficient matrix in terms of lag 1, the parameter estimates, and their significance, which can indicate how well the model fits the data.

The second table schematically represents the parameter estimates and allows for easy verification of their significance in matrix form.

In the last table, the first column gives the left-hand-side variable of the equation; the second column is the parameter name ARl_i_j , which indicates the (i, j) th element of the lag l autoregressive coefficient; the last column is the regressor that corresponds to the displayed parameter.

Figure 32.3 Model Type and Parameter Estimates

The VARMAX Procedure						
Type of Model		VAR(1)				
Estimation Method		Least Squares Estimation				
AR						
Lag	Variable	y1	y2			
1	y1	1.15977	-0.51058			
	y2	0.54634	0.38499			
Schematic Representation						
Variable/ Lag	AR1					
y1	+-					
y2	++					
+ is > 2*std error, - is < -2*std error, . is between, * is N/A						
Model Parameter Estimates						
Equation	Parameter	Estimate	Standard Error	t Value	Pr > t	Variable
y1	AR1_1_1	1.15977	0.05508	21.06	0.0001	y1(t-1)
	AR1_1_2	-0.51058	0.05898	-8.66	0.0001	y2(t-1)
y2	AR1_2_1	0.54634	0.05779	9.45	0.0001	y1(t-1)
	AR1_2_2	0.38499	0.06188	6.22	0.0001	y2(t-1)

The fitted VAR(1) model with estimated standard errors in parentheses is given as

$$y_t = \begin{pmatrix} 1.160 & -0.511 \\ (0.055) & (0.059) \\ 0.546 & 0.385 \\ (0.058) & (0.062) \end{pmatrix} y_{t-1} + \epsilon_t$$

Clearly, all parameter estimates in the coefficient matrix Φ_1 are significant.

The model can also be written as two univariate regression equations.

$$y_{1t} = 1.160 y_{1,t-1} - 0.511 y_{2,t-1} + \epsilon_{1t}$$

$$y_{2t} = 0.546 y_{1,t-1} + 0.385 y_{2,t-1} + \epsilon_{2t}$$

The table in Figure 32.4 shows the innovation covariance matrix estimates and the various information criteria results. The smaller value of information criteria fits the data better when it is compared to other models. The variable names in the covariance matrix are printed for convenience; y_1 means the innovation for y_1 , and y_2 means the innovation for y_2 .

Figure 32.4 Innovation Covariance Estimates and Information Criteria

Covariances of Innovations			
Variable	y1	y2	
y1	1.28875	0.39751	
y2	0.39751	1.41839	
Information Criteria			
AICC	0.554443		
HQC	0.595201		
AIC	0.552777		
SBC	0.65763		
FPEC	1.738092		

Figure 32.5 shows the cross covariances of the residuals. The values of the lag zero are slightly different from Figure 32.4 due to the different degrees of freedom.

Figure 32.5 Multivariate Diagnostic Checks

Cross Covariances of Residuals				
Lag	Variable	y1	y2	
0	y1	1.26271	0.38948	
	y2	0.38948	1.38974	
1	y1	0.03121	0.05675	
	y2	-0.04646	-0.05398	
2	y1	0.08134	0.10599	
	y2	0.03482	-0.01549	
3	y1	0.01644	0.11734	
	y2	0.00609	0.11414	

Figure 32.6 and Figure 32.7 show tests for white noise residuals. The output shows that you cannot reject the null hypothesis that the residuals are uncorrelated.

The VARMAX procedure provides diagnostic checks for the univariate form of the equations. The table in Figure 32.8 describes how well each univariate equation fits the data. From two univariate regression equations in Figure 32.3, the values of R^2 in the second column are 0.84 and 0.80 for each equation. The standard deviations in the third column are the square roots of the diagonal elements of the covariance matrix from Figure 32.4. The F statistics are in the fourth column for hypotheses to test $\phi_{11} = \phi_{12} = 0$ and $\phi_{21} = \phi_{22} = 0$, respectively, where ϕ_{ij} is the (i, j) th element of the matrix Φ_1 . The last column shows the p -values of the F statistics. The results show that each univariate model is significant.

Figure 32.8 Univariate Diagnostic Checks

Univariate Model ANOVA Diagnostics				
Variable	R-Square	Standard Deviation	F Value	Pr > F
y1	0.8351	1.13523	491.25	<.0001
y2	0.7906	1.19096	366.29	<.0001

The check for white noise residuals in terms of the univariate equation is shown in Figure 32.9. This output contains information that indicates whether the residuals are correlated and heteroscedastic. In the first table, the second column contains the Durbin-Watson test statistics to test the null hypothesis that the residuals are uncorrelated. The third and fourth columns show the Jarque-Bera normality test statistics and their p -values to test the null hypothesis that the residuals have normality. The last two columns show F statistics and their p -values for ARCH(1) disturbances to test the null hypothesis that the residuals have equal covariances. The second table includes F statistics and their p -values for AR(1), AR(1,2), AR(1,2,3) and AR(1,2,3,4) models of residuals to test the null hypothesis that the residuals are uncorrelated.

Bayesian Vector Autoregressive Process

The Bayesian vector autoregressive (BVAR) model is used to avoid problems of collinearity and over-parameterization that often occur with the use of VAR models. BVAR models do this by imposing priors on the AR parameters.

The following statements fit a BVAR(1) model to the simulated data. You specify the PRIOR= option with the hyperparameters. The LAMBDA=0.9 and THETA=0.1 options are hyperparameters controlling the prior covariance. Part of the VARMAX procedure output is shown in Figure 32.11.

```

/*--- Bayesian Vector Autoregressive Process ---*/

proc varmax data=simul1;
  model y1 y2 / p=1 noint
          prior=(lambda=0.9 theta=0.1);
run;

```

The output in Figure 32.11 shows that parameter estimates are slightly different from those in Figure 32.3. By choosing the appropriate priors, you might be able to get more accurate forecasts by using a BVAR model rather than by using an unconstrained VAR model. See the section “Bayesian VAR and VARX Modeling” on page 2139 for details.

Vector Error Correction Model

A vector error correction model (VECM) can lead to a better understanding of the nature of any nonstationarity among the different component series and can also improve longer term forecasting over an unconstrained model.

The VECM(p) form with the cointegration rank $r (\leq k)$ is written as

$$\Delta \mathbf{y}_t = \boldsymbol{\delta} + \Pi \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

where Δ is the differencing operator, such that $\Delta \mathbf{y}_t = \mathbf{y}_t - \mathbf{y}_{t-1}$; $\Pi = \boldsymbol{\alpha}\boldsymbol{\beta}'$, where $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ are $k \times r$ matrices; Φ_i^* is a $k \times k$ matrix.

It has an equivalent VAR(p) representation as described in the preceding section.

$$\mathbf{y}_t = \boldsymbol{\delta} + (I_k + \Pi + \Phi_1^*)\mathbf{y}_{t-1} + \sum_{i=2}^{p-1} (\Phi_i^* - \Phi_{i-1}^*)\mathbf{y}_{t-i} - \Phi_{p-1}^*\mathbf{y}_{t-p} + \boldsymbol{\epsilon}_t$$

where I_k is a $k \times k$ identity matrix.

Example of Vector Error Correction Model

An example of the second-order nonstationary vector autoregressive model is

$$\mathbf{y}_t = \begin{pmatrix} -0.2 & 0.1 \\ 0.5 & 0.2 \end{pmatrix} \mathbf{y}_{t-1} + \begin{pmatrix} 0.8 & 0.7 \\ -0.4 & 0.6 \end{pmatrix} \mathbf{y}_{t-2} + \boldsymbol{\epsilon}_t$$

with

$$\Sigma = \begin{pmatrix} 100 & 0 \\ 0 & 100 \end{pmatrix} \text{ and } \mathbf{y}_0 = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

This process can be given the following VECM(2) representation with the cointegration rank one:

$$\Delta \mathbf{y}_t = \begin{pmatrix} -0.4 \\ 0.1 \end{pmatrix} (1, -2) \mathbf{y}_{t-1} - \begin{pmatrix} 0.8 & 0.7 \\ -0.4 & 0.6 \end{pmatrix} \Delta \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

The following PROC IML statements generate simulated data for the VECM(2) form specified above and plot the data as shown in [Figure 32.12](#):

```
proc iml;
  sig = 100*i(2);
  phi = {-0.2 0.1, 0.5 0.2, 0.8 0.7, -0.4 0.6};
  call varmasim(y,phi) sigma=sig n=100 initial=0
              seed=45876;

  cn = {'y1' 'y2'};
  create simul2 from y[colname=cn];
  append from y;
quit;

data simul2;
  set simul2;
  date = intnx( 'year', '01jan1900'd, _n_-1 );
  format date year4. ;
run;

proc timeseries data=simul2 vectorplot=series;
  id date interval=year;
  var y1 y2;
run;
```

Figure 32.12 Plot of Generated Data Process

Cointegration Testing

The following statements use the Johansen cointegration rank test. The `COINTTEST=(JOHANSEN)` option does the Johansen trace test and is equivalent to specifying `COINTTEST` with no additional options or the `COINTTEST=(JOHANSEN=(TYPE=TRACE))` option.

```
/*--- Cointegration Test ---*/

proc varmax data=simul2;
  model y1 y2 / p=2 noint dftest cointtest=(johansen);
run;
```

Figure 32.13 shows the output for Dickey-Fuller tests for the nonstationarity of each series and Johansen cointegration rank test between series.

Figure 32.13 Dickey-Fuller Tests and Cointegration Rank Test

The VARMAX Procedure						
Unit Root Test						
Variable	Type	Rho	Pr < Rho	Tau	Pr < Tau	
y1	Zero Mean	1.47	0.9628	1.65	0.9755	
	Single Mean	-0.80	0.9016	-0.47	0.8916	
	Trend	-10.88	0.3573	-2.20	0.4815	
y2	Zero Mean	-0.05	0.6692	-0.03	0.6707	
	Single Mean	-6.03	0.3358	-1.72	0.4204	
	Trend	-50.49	0.0003	-4.92	0.0006	
Cointegration Rank Test Using Trace						
H0:	H1:			5%	Drift	Drift in
Rank=r	Rank>r	Eigenvalue	Trace	Critical Value	in ECM	Process
0	0	0.5086	70.7279	12.21	NOINT	Constant
1	1	0.0111	1.0921	4.14		

In Dickey-Fuller tests, the second column specifies three types of models, which are zero mean, single mean, or trend. The third column (Rho) and the fifth column (Tau) are the test statistics for unit root testing. Other columns are their p -values. You can see that both series have unit roots. For a description of Dickey-Fuller tests, see the section “[PROBDF Function for Dickey-Fuller Tests](#)” on page 162 in Chapter 5, “[SAS Macros and Functions](#).”

In the cointegration rank test, the last two columns explain the drift in the model or process. Since the NOINT option is specified, the model is

$$\Delta \mathbf{y}_t = \Pi \mathbf{y}_{t-1} + \Phi_1^* \Delta \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

The column Drift In ECM means there is no separate drift in the error correction model, and the column Drift In Process means the process has a constant drift before differencing.

H0 is the null hypothesis, and H1 is the alternative hypothesis. The first row tests $r = 0$ against $r > 0$; the second row tests $r = 1$ against $r > 1$. The Trace test statistics in the fourth column are computed by $-T \sum_{i=r+1}^k \log(1 - \lambda_i)$ where T is the available number of observations and λ_i is the eigenvalue in the third column. By default, the critical values at 5% significance level are used for testing. You can compare the test statistics and critical values in each row. There is one cointegrated process in this example since the Trace statistic for testing $r = 0$ against $r > 0$ is greater than the critical value, but the Trace statistic for testing $r = 1$ against $r > 1$ is not greater than the critical value.

The following statements fit a VECM(2) form to the simulated data. From the result in [Figure 32.13](#), the time series are cointegrated with rank=1. You specify the ECM= option with the RANK=1 option. For normalizing the value of the cointegrated vector, you specify the normalized variable

with the NORMALIZE= option. The PRINT=(IARR) option provides the VAR(2) representation. The VARMAX procedure output is shown in Figure 32.14 through Figure 32.16.

```

/*--- Vector Error-Correction Model ---*/

proc varmax data=simul2;
  model y1 y2 / p=2 noint lagmax=3
           ecm=(rank=1 normalize=y1)
           print=(iarr estimates);
run;

```

The ECM= option produces the estimates of the long-run parameter, β , and the adjustment coefficient, α . In Figure 32.14, “1” indicates the first column of the α and β matrices. Since the cointegration rank is 1 in the bivariate system, α and β are two-dimensional vectors. The estimated cointegrating vector is $\hat{\beta} = (1, -1.96)'$. Therefore, the long-run relationship between y_{1t} and y_{2t} is $y_{1t} = 1.96y_{2t}$. The first element of $\hat{\beta}$ is 1 since y_1 is specified as the normalized variable.

Figure 32.14 Parameter Estimates for the VECM(2) Form

The VARMAX Procedure		
Type of Model		VECM(2)
Estimation Method	Maximum Likelihood Estimation	
Cointegrated Rank		1

y2		0.10667

Figure 32.15 shows the parameter estimates in terms of lag one coefficients, y_{t-1} , and lag one first differenced coefficients, Δy_{t-1} , and their significance. “Alpha * Beta” indicates the coefficients of y_{t-1} and is obtained by multiplying the “Alpha” and “Beta” estimates in Figure 32.14. The parameter AR1_i_j corresponds to the elements in the “Alpha * Beta” matrix. The t values and p -values corresponding to the parameters AR1_i_j are missing since the parameters AR1_i_j have non-Gaussian distributions. The parameter AR2_i_j corresponds to the elements in the differenced lagged AR coefficient matrix. The “D_” prefixed to a variable name in Figure 32.15 implies differencing.

Figure 32.15 Parameter Estimates for the VECM(2) Form

	AR2_1_1	-0.74332	0.04526	-16.42	0.0001	D_y1 (t-1)
D_y2	AR2_1_2	-0.74621	0.04769	-15.65	0.0001	D_y2 (t-1)
	AR1_2_1	0.10667	0.05146			y1 (t-1)
	AR1_2_2	-0.20862	0.10064			y2 (t-1)
	AR2_2_1	0.40493	0.04867	8.32	0.0001	D_y1 (t-1)
	AR2_2_2	-0.57157	0.05128	-11.15	0.0001	D_y2 (t-1)

The fitted model is given as

$$\Delta \mathbf{y}_t = \begin{pmatrix} -0.467 & 0.913 \\ (0.048) & (0.094) \\ 0.107 & -0.209 \\ (0.051) & (0.100) \end{pmatrix} \mathbf{y}_{t-1} + \begin{pmatrix} -0.743 & -0.746 \\ (0.045) & (0.048) \\ 0.405 & -0.572 \\ (0.049) & (0.051) \end{pmatrix} \Delta \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

Figure 32.16 Change the VECM(2) Form to the VAR(2) Model

Infinite Order AR Representation				
Lag	Variable	y1	y2	
1	y1	-0.21013	0.16674	
	y2	0.51160	0.21980	
2	y1	0.74332	0.74621	
	y2	-0.40493	0.57157	
3	y1	0.00000	0.00000	
	y2	0.00000	0.00000	

The PRINT=(IARR) option in the previous SAS statements prints the reparameterized coefficient estimates. For the LAGMAX=3 in the SAS statements, the coefficient matrix of lag 3 is zero.

The VECM(2) form in Figure 32.16 can be rewritten as the following second-order vector autoregressive model:

$$\mathbf{y}_t = \begin{pmatrix} -0.210 & 0.167 \\ 0.512 & 0.220 \end{pmatrix} \mathbf{y}_{t-1} + \begin{pmatrix} 0.743 & 0.746 \\ -0.405 & 0.572 \end{pmatrix} \mathbf{y}_{t-2} + \boldsymbol{\epsilon}_t$$

Bayesian Vector Error Correction Model

Bayesian inference on a cointegrated system begins by using the priors of $\boldsymbol{\beta}$ obtained from the VECM(p) form. Bayesian vector error correction models can improve forecast accuracy for cointegrated processes.

The following statements fit a BVECM(2) form to the simulated data. You specify both the PRIOR= and ECM= options for the Bayesian vector error correction model. The VARMAX procedure output is shown in Figure 32.17.

```

/*--- Bayesian Vector Error-Correction Model ---*/

proc varmax data=simul2;
  model y1 y2 / p=2 noint
             prior=( lambda=0.5 theta=0.2 )
             ecm=( rank=1 normalize=y1 )
             print=(estimates);
run;

```

Figure 32.17 shows the model type fitted to the data, the estimates of the adjustment coefficient ($\boldsymbol{\alpha}$), the parameter estimates in terms of lag one coefficients (\mathbf{y}_{t-1}), and lag one first differenced coefficients ($\Delta\mathbf{y}_{t-1}$).

Vector Autoregressive Process with Exogenous Variables

A VAR process can be affected by other observable variables that are determined outside the system of interest. Such variables are called exogenous (independent) variables. Exogenous variables can be stochastic or nonstochastic. The process can also be affected by the lags of exogenous variables. A model used to describe this process is called a VARX(p,s) model.

The VARX(p,s) model is written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

where $\mathbf{x}_t = (x_{1t}, \dots, x_{rt})'$ is an r -dimensional time series vector and Θ_i^* is a $k \times r$ matrix.

For example, a VARX(1,0) model is

$$\mathbf{y}_t = \boldsymbol{\delta} + \Phi_1 \mathbf{y}_{t-1} + \Theta_0^* \mathbf{x}_t + \boldsymbol{\epsilon}_t$$

where $\mathbf{y}_t = (y_{1t}, y_{2t}, y_{3t})'$ and $\mathbf{x}_t = (x_{1t}, x_{2t})'$.

The following statements fit the VARX(1,0) model to the given data:

```

data grunfeld;
  input year y1 y2 y3 x1 x2 x3;
  label y1='Gross Investment GE'
        y2='Capital Stock Lagged GE'

The fitted model is given as

$$\begin{pmatrix} y_{1t} \\ y_{2t} \\ y_{3t} \end{pmatrix} = \begin{pmatrix} -12.013 \\ (27.471) \\ 702.086 \\ (256.480) \\ -22.421 \\ (10.312) \end{pmatrix} + \begin{pmatrix} 1.693 & -0.009 \\ (0.544) & (0.054) \\ -6.099 & 2.580 \\ (5.078) & (0.501) \\ -0.023 & -0.013 \\ (0.204) & (0.020) \end{pmatrix} \begin{pmatrix} x_{1t} \\ x_{2t} \end{pmatrix} \\
 + \begin{pmatrix} 0.237 & 0.008 & 0.029 \\ (0.207) & (0.016) & (0.049) \\ -2.467 & 0.164 & -0.841 \\ (1.930) & (0.152) & (0.453) \\ 0.951 & 0.002 & 0.938 \\ (0.078) & (0.006) & (0.018) \end{pmatrix} \begin{pmatrix} y_{1,t-1} \\ y_{2,t-1} \\ y_{3,t-1} \end{pmatrix} + \begin{pmatrix} \epsilon_{1t} \\ \epsilon_{2t} \\ \epsilon_{3t} \end{pmatrix}$$

Parameter Estimation and Testing on Restrictions

In the previous example, the VARX(1,0) model is written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \Theta_0^* \mathbf{x}_t + \Phi_1 \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

with

$$\Theta_0^* = \begin{pmatrix} \theta_{11}^* & \theta_{12}^* \\ \theta_{21}^* & \theta_{22}^* \\ \theta_{31}^* & \theta_{32}^* \end{pmatrix} \quad \Phi_1 = \begin{pmatrix} \phi_{11} & \phi_{12} & \phi_{13} \\ \phi_{21} & \phi_{22} & \phi_{23} \\ \phi_{31} & \phi_{32} & \phi_{33} \end{pmatrix}$$

In [Figure 32.20](#) of the preceding section, you can see several insignificant parameters. For example, the coefficients XL0_1_2, AR1_1_2, and AR1_3_2 are insignificant.

The following statements restrict the coefficients of $\theta_{12}^* = \phi_{12} = \phi_{32} = 0$ for the VARX(1,0) model.

```

/*--- Models with Restrictions and Tests ---*/

proc varmax data=grunfeld;
  model y1-y3 = x1 x2 / p=1 print=(estimates);
  restrict XL(0,1,2)=0, AR(1,1,2)=0, AR(1,3,2)=0;
run;

```

The output in [Figure 32.21](#) shows that three parameters θ_{12}^* , ϕ_{12} , and ϕ_{32} are replaced by the restricted values, zeros. In the schematic representation of parameter estimates, the three restricted parameters θ_{12}^* , ϕ_{12} , and ϕ_{32} are replaced by *.

Figure 32.21 Parameter Estimation with Restrictions

The VARMAX Procedure					
XLag					
	Lag	Variable	x1	x2	
	0	y1	1.67592	0.00000	
		y2	-6.30880	2.65308	
		y3	-0.03576	-0.00919	
AR					
	Lag	Variable	y1	y2	y3
	1	y1	0.27671	0.00000	0.01747
		y2	-2.16968	0.10945	-0.93053
		y3	0.96398	0.00000	0.93412
Schematic Representation					
Variable/ Lag	C	XL0	AR1		
y1	.	++	.*.		
y2	+	.+	..-		
y3	-	..	+++		
+ is > 2*std error, -					
is < -2*std error, .					
is between, * is N/A					

The output in Figure 32.22 shows the estimates of the Lagrangian parameters and their significance. Based on the p -values associated with the Lagrangian parameters, you cannot reject the null hypotheses $\theta_{12}^* = 0$, $\phi_{12} = 0$, and $\phi_{32} = 0$ with the 0.05 significance level.

Figure 32.22 RESTRICT Statement Results

Testing of the Restricted Parameters				
Parameter	Estimate	Standard Error	t Value	Pr > t
XL0_1_2	1.74969	21.44026	0.08	0.9389
AR1_1_2	30.36254	70.74347	0.43	0.6899
AR1_3_2	55.42191	164.03075	0.34	0.7524

The TEST statement in the following example tests $\phi_{31} = 0$ and $\theta_{12}^* = \phi_{12} = \phi_{32} = 0$ for the VARX(1,0) model:

```

proc varmax data=grunfeld;
  model y1-y3 = x1 x2 / p=1;
  test AR(1,3,1)=0;
  test XL(0,1,2)=0, AR(1,1,2)=0, AR(1,3,2)=0;
run;

```

The output in Figure 32.23 shows that the first column in the output is the index corresponding to each TEST statement. You can reject the hypothesis test $\phi_{31} = 0$ at the 0.05 significance level, but you cannot reject the joint hypothesis test $\theta_{12}^* = \phi_{12} = \phi_{32} = 0$ at the 0.05 significance level.

Figure 32.23 TEST Statement Results

The VARMAX Procedure				
Testing of the Parameters				
Test	DF	Chi-Square	Pr > ChiSq	
1	1	150.31	<.0001	
2	3	0.34	0.9522	

Causality Testing

The following statements use the CAUSAL statement to compute the Granger causality test for a VAR(1) model. For the Granger causality tests, the autoregressive order should be defined by the P= option in the MODEL statement. The variable groups are defined in the MODEL statement as well. Regardless of whether the variables specified in the GROUP1= and GROUP2= options are designated as dependent or exogenous (independent) variables in the MODEL statement, the CAUSAL statement fits the VAR(p) model by considering the variables in the two groups as dependent variables.

```

/*--- Causality Testing ---*/

proc varmax data=grunfeld;
  model y1-y3 = x1 x2 / p=1 noprint;
  causal group1=(x1) group2=(y1-y3);
  causal group1=(y3) group2=(y1 y2);
run;

```

The output in Figure 32.24 is associated with the CAUSAL statement. The first CAUSAL statement fits the VAR(1) model by using the variables y_1 , y_2 , y_3 , and x_1 . The second CAUSAL statement fits the VAR(1) model by using the variables y_1 , y_3 , and y_2 .

Figure 32.24 CAUSAL Statement Results

The VARMAX Procedure			
Granger-Causality Wald Test			
Test	DF	Chi-Square	Pr > ChiSq
1	3	2.40	0.4946
2	2	262.88	<.0001
Test 1: Group 1 Variables: x1			
Group 2 Variables: y1 y2 y3			
Test 2: Group 1 Variables: y3			
Group 2 Variables: y1 y2			

The null hypothesis of the Granger causality test is that GROUP1 is influenced only by itself, and not by GROUP2.

The first column in the output is the index corresponding to each CAUSAL statement. The output shows that you cannot reject that *x1* is influenced by itself and not by (*y1*, *y2*, *y3*) at the 0.05 significance level for Test 1. You can reject that *y3* is influenced by itself and not by (*y1*, *y2*) for Test 2. See the section “VAR and VARX Modeling” on page 2133 for details.

Syntax: VARMAX Procedure

```

Functional Summary

The statements and options used with the VARMAX procedure are summarized in the following table:

Table 32.1 VARMAX Functional Summary

Description	Statement	Option
Data Set Options		
specify the input data set	VARMAX	DATA=
write parameter estimates to an output data set	VARMAX	OUTEST=
include covariances in the OUTEST= data set	VARMAX	OUTCOV
write the diagnostic checking tests for a model and the cointegration test results to an output data set	VARMAX	OUTSTAT=
write actuals, predictions, residuals, and confidence limits to an output data set	OUTPUT	OUT=
write the conditional covariance matrix to an output data set	GARCH	OUTHT=
BY Groups		
specify BY-group processing	BY	
ID Variable		
specify identifying variable	ID	
specify the time interval between observations	ID	INTERVAL=
control the alignment of SAS Date values	ID	ALIGN=
Options to Control the Optimization Process		
specify the optimization options	NLOPTIONS	
Printing Control Options		
specify how many lags to print results	MODEL	LAGMAX=
suppress the printed output	MODEL	NOPRINT
request all printing options	MODEL	PRINTALL
request the printing format	MODEL	PRINTFORM=
controls plots produced through ODS GRAPHICS	VARMAX	PLOTS=
PRINT= Option		
print the correlation matrix of parameter estimates	MODEL	CORRB
print the cross-correlation matrices of independent variables	MODEL	CORRX
print the cross-correlation matrices of dependent variables	MODEL	CORRY
print the covariance matrices of prediction errors	MODEL	COVPE
print the cross-covariance matrices of the independent variables	MODEL	COVX

Table 32.1 continued

Description	Statement	Option
print the cross-covariance matrices of the dependent variables	MODEL	COVY
print the covariance matrix of parameter estimates	MODEL	COVB
print the decomposition of the prediction error covariance matrix	MODEL	DECOMPOSE
print the residual diagnostics	MODEL	DIAGNOSE
print the contemporaneous relationships among the components of the vector time series	MODEL	DYNAMIC
print the parameter estimates	MODEL	ESTIMATES
print the infinite order AR representation	MODEL	IARR
print the impulse response function	MODEL	IMPULSE=
print the impulse response function in the transfer function	MODEL	IMPULSX=
print the partial autoregressive coefficient matrices	MODEL	PARCOEF
print the partial canonical correlation matrices	MODEL	PCANCORR
print the partial correlation matrices	MODEL	PCORR
print the eigenvalues of the companion matrix	MODEL	ROOTS
print the Yule-Walker estimates	MODEL	YW
Model Estimation and Order Selection Options		
center the dependent variables	MODEL	CENTER
specify the degrees of differencing for the specified model variables	MODEL	DIF=
specify the degrees of differencing for all independent variables	MODEL	DIFX=
specify the degrees of differencing for all dependent variables	MODEL	DIFY=
specify the vector error correction model	MODEL	ECM=
specify the estimation method	MODEL	METHOD=
select the tentative order	MODEL	MINIC=
suppress the current values of independent variables	MODEL	NOCURRENTX
suppress the intercept parameters	MODEL	NOINT
specify the number of seasonal periods	MODEL	NSEASON=
specify the order of autoregressive polynomial	MODEL	P=
specify the Bayesian prior model	MODEL	PRIOR=
specify the order of moving-average polynomial	MODEL	Q=
center the seasonal dummies	MODEL	SCENTER
specify the degree of time trend polynomial	MODEL	TREND=
specify the denominator for error covariance matrix estimates	MODEL	VARDEF=
specify the lag order of independent variables	MODEL	XLAG=
GARCH Related Options		
specify the GARCH-type model	GARCH	FORM=

Table 32.1 *continued*

Description	Statement	Option
specify the order of the GARCH polynomial	GARCH	P=
specify the order of the ARCH polynomial	GARCH	Q=
Cointegration Related Options		
print the results from the weak exogeneity test of the long-run parameters	COINTEG	EXOGENEITY
specify the restriction on the cointegrated coefficient matrix	COINTEG	H=
specify the restriction on the adjustment coefficient matrix	COINTEG	J=
specify the variable name whose cointegrating vectors are normalized	COINTEG	NORMALIZE=
specify a cointegration rank	COINTEG	RANK=
print the Johansen cointegration rank test	MODEL	COINTTEST= (JOHANSEN=)
print the Stock-Watson common trends test	MODEL	COINTTEST=(SW=)
print the Dickey-Fuller unit root test	MODEL	DFTEST=
Tests and Restrictions on Parameters		
test the Granger causality	CAUSAL	GROUP1= GROUP2=
place and test restrictions on parameter estimates	RESTRICT	
test hypotheses on parameter estimates	TEST	
Forecasting Control Options		
specify the size of confidence limits for forecasting	OUTPUT	ALPHA=
start forecasting before end of the input data	OUTPUT	BACK=
specify how many periods to forecast	OUTPUT	LEAD=
suppress the printed forecasts	OUTPUT	NOPRINT

PROC VARMAX Statement

PROC VARMAX *options* ;

The following options can be used in the PROC VARMAX statement:

DATA=SAS-data-set

specifies the input SAS data set. If the DATA= option is not specified, the PROC VARMAX statement uses the most recently created SAS data set.

OUTEST=SAS-data-set

writes the parameter estimates to the output data set.

COVOUT**OUTCOV**

writes the covariance matrix for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is specified.

OUTSTAT=SAS-data-set

writes residual diagnostic results to an output data set. If the COINTTEST=(JOHANSEN) option is specified, the results of this option are also written to the output data set.

The following statements are the examples of these options in the PROC VARMAX statement:

```
proc varmax data=one outest=est outcov outstat=stat;
  model y1-y3 / p=1;
run;
```

```
proc varmax data=one outest=est outstat=stat;
  model y1-y3 / p=1 cointtest=(johansen);
run;
```

PLOTS<(global-plot-option)> = plot-request-option <(options)>

PLOTS<(global-plot-option)> = (plot-request-option <(options)> ... plot-request-option <(options)>)

controls the plots produced through ODS Graphics. When you specify only one plot, you can omit the parentheses around the plot request. Some examples follow:

```
plots=none
plots=all
plots(unpack)=residual(residual normal)
plots=(forecasts model)
```

You must enable ODS Graphics before requesting plots as shown in the following example. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*).

```
ods graphics on;

proc varmax data=one plots=impulse(simple);
  model y1-y3 / p=1;
run;

proc varmax data=one plots=(model residual);
  model y1-y3 / p=1;
run;

proc varmax data=one plots=forecasts;
  model y1-y3 / p=1;
  output lead=12;
run;
```

The first VARMAX program produces the simple response impulse plots. The second VARMAX program produces the plots associated with the model and prediction errors. The plots associated with prediction errors are the ACF, PACF, IACF, distribution, white-noise, and Normal quantile plots and the prediction error plot. The third VARMAX program produces the FORECASTS and FORECASTSONLY plots.

The *global-plot-option* applies to the impulse and prediction error analysis plots generated by the VARMAX procedure. The following *global-plot-option* is available:

UNPACK breaks a graphic that is otherwise paneled into individual component plots.

The following *plot-request-options* are available:

ALL produces all plots appropriate for the particular analysis.

FORECASTS < (*forecasts-plot-options*) > produces plots of the forecasts. The forecasts-only plot that shows the multistep forecasts in the forecast region is produced by default. The following *forecasts-plot-options* are available:

ALL produces the FORECASTSONLY and the FORECASTS plots. This is the default.

FORECASTS produces a plot that shows the one-step-ahead as well as the multistep forecasts.

FORECASTSONLY produces a plot that shows only the multistep forecasts.

IMPULSE < (*impulse-plot-options*) > produces the plots of impulse response function and the impulse response of the transfer function.

ALL produces all impulse plots. This is the default.

ACCUM produces the accumulated impulse plot.

ORTH produces the orthogonalized impulse plot.

SIMPLE produces the simple impulse plot.

MODEL produces plots of dependent variables listed in the MODEL statement and plots of the one-step-ahead predicted values for each dependent variables.

NONE suppresses all plots.

RESIDUAL < (*residual-plot-options*) > produces plots associated with the prediction errors obtained after modeling the data. The following *residual-plot-options* are available:

ALL produces all plots associated with the analysis of the prediction errors. This is the default.

RESIDUAL produces prediction error plot.

DIAGNOSTICS produces a panel of plots useful in assessing the autocorrelations and white-noise of the prediction errors. The panel consists of the following:

- the autocorrelation plot of the prediction errors

- the partial autocorrelation plot of the prediction errors
- the inverse autocorrelation plot of the prediction errors
- the log scaled white noise plot of the prediction errors

NORMAL

produces a panel of plots useful in assessing normality of the prediction errors. The panel consists of the following:

- distribution of the prediction errors with overlaid the normal curve
- normal quantile plot of the prediction errors

Other Options

In addition, any of the following MODEL statement options can be specified in the PROC VARMAX statement, which is equivalent to specifying the option for every MODEL statement: CENTER, DFTEST=, DIF=, DIFX=, DIFY=, LAGMAX=, METHOD=, MINIC=, NOCURRENTX, NOINT, NOPRINT, NSEASON=, P=, PRINT=, PRINTALL, PRINTFORM=, Q=, SCENTER, TREND=, VARDEF=, and XLAG= options.

The following is an example of the options in the PROC VARMAX statement:

```
proc varmax data=one lagmax=3 method=ml;
  model y1-y3 / p=1;
run;
```

BY Statement

BY *variables* ;

A BY statement can be used with PROC VARMAX to obtain separate analyses on observations in groups defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the VARMAX procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

- Create an index on the BY variables using the DATASETS procedure.

For more information about the BY statement, see in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

The following is an example of the BY statement:

```
proc varmax data=one;
  by region;
  model y1-y3 / p=1;
run;
```

CAUSAL Statement

CAUSAL *GROUP1*=(variables) *GROUP2*=(variables) ;

A CAUSAL statement prints the Granger causality test by fitting the VAR(p) model by using all variables defined in GROUP1 and GROUP2. Any number of CAUSAL statements can be specified. The CAUSAL statement proceeds with the MODEL statement and uses the variables and the autoregressive order, p , specified in the MODEL statement. Variables in the GROUP1= and GROUP2= options should be defined in the MODEL statement. If the P=0 option is specified in the MODEL statement, the CAUSAL statement is not applicable.

The null hypothesis of the Granger causality test is that GROUP1 is influenced only by itself, and not by GROUP2. If the hypothesis test fails to reject the null, then the variables listed in GROUP1 might be considered as independent variables.

See the section “VAR and VARX Modeling” on page 2133 for details.

The following is an example of the CAUSAL statement. You specify the CAUSAL statement with the GROUP1= and GROUP2= options.

```
proc varmax data=one;
  model y1-y3 = x1 / p=1;
  causal group1=(x1) group2=(y1-y3);
  causal group1=(y2) group2=(y1 y3);
run;
```

The first CAUSAL statement fits the VAR(1) model by using the variables y_1 , y_2 , y_3 , and x_1 and tests the null hypothesis that x_1 causes the other variables, y_1 , y_2 , and y_3 , but the other variables do not cause x_1 . The second CAUSAL statement fits the VAR(1) model by using the variables y_1 , y_3 , and y_2 and tests the null hypothesis that y_2 causes the other variables, y_1 and y_3 , but the other variables do not cause y_2 .

COINTEG Statement

```
COINTEG RANK=number < H=(matrix) > < J=(matrix) >
        < EXOGENEITY > < NORMALIZE=variable > ;
```

The COINTEG statement fits the vector error correction model to the data, tests the restrictions of the long-run parameters and the adjustment parameters, and tests for the weak exogeneity in the long-run parameters. The cointegrated system uses the maximum likelihood analysis proposed by Johansen and Juselius (1990) and Johansen (1995a, 1995b). Only one COINTEG statement is allowed.

You specify the ECM= option in the MODEL statement or the COINTEG statement to fit the VECM(p). The P= option in the MODEL statement is used to specify the autoregressive order of the VECM.

The following statements are equivalent for fitting a VECM(2).

```
proc varmax data=one;
  model y1-y3 / p=2 ecm=(rank=1);
run;
```

```
proc varmax data=one;
  model y1-y3 / p=2;
  cointeg rank=1;
run;
```

To test restrictions of either α or β or both, you specify either J= or H= or both, respectively. You specify the EXOGENEITY option in the COINTEG statement for tests of the weak exogeneity in the long-run parameters.

The following is an example of the COINTEG statement.

```
proc varmax data=one;
  model y1-y3 / p=2;
  cointeg rank=1 h=(1 0, -1 0, 0 1)
                j=(1 0, 0 0, 0 1) exogeneity;
run;
```

The following options can be used in the COINTEG statement:

EXOGENEITY

formulates the likelihood ratio tests for testing weak exogeneity in the long-run parameters. The null hypothesis is that one variable is weakly exogenous for the others.

H=(matrix)

specifies the restrictions H on the $k \times r$ or $(k + 1) \times r$ cointegrated coefficient matrix β such that $\beta = H\phi$, where H is known and ϕ is unknown. If the VECM(p) is specified with the COINTEG statement or with the ECM= option in the MODEL statement and the ECTREND option is not included with the ECM= specification, then the H matrix has dimension $k \times m$.

If the $VECM(p)$ is specified with the COINTEG statement or with the ECM= option in the MODEL statement and the ECTREND option is also used, then the H matrix has dimension $(k + 1) \times m$. Here k is the number of dependent variables, and m is $r \leq m < k$ where r is defined with the RANK= r option.

For example, consider a system that contains four variables and the RANK=1 option with $\beta = (\beta_1, \beta_2, \beta_3, \beta_4)'$. The restriction matrix for the test of $\beta_1 + \beta_2 = 0$ can be specified as

```
cointeg rank=1 h=(1 0 0, -1 0 0, 0 1 0, 0 0 1);
```

Here the matrix H is 4×3 where $k = 4$ and $m = 3$, and each row of the matrix H is separated by commas.

When the series has no separate deterministic trend, the constant term should be restricted by $\alpha'_1 \delta = 0$. In the preceding example, the β can be either $\beta = (\beta_1, \beta_2, \beta_3, \beta_4, 1)'$ or $\beta = (\beta_1, \beta_2, \beta_3, \beta_4, t)'$. You can specify the restriction matrix for the previous test of $\beta_1 + \beta_2 = 0$ as follows:

```
cointeg rank=1
h=(1 0 0 0, -1 0 0 0, 0 1 0 0, 0 0 1 0, 0 0 0 1);
```

When the cointegrated system contains three dependent variables and the RANK=2 option, you can specify the restriction matrix for the test of $\beta_{1j} = -\beta_{2j}$ for $j = 1, 2$ as follows:

```
cointeg rank=2 h=(1 0, -1 0, 0 1);
```

J=(matrix)

specifies the restrictions J on the $k \times r$ adjustment matrix α such that $\alpha = J\psi$, where J is known and ψ is unknown. The $k \times m$ matrix J is specified by using this option, where k is the number of dependent variables, m is $r \leq m < k$, and r is defined with the RANK= r option.

For example, when the system contains four variables and the RANK=1 option is used, you can specify the restriction matrix for the test of $\alpha_j = 0$ for $j = 2, 3, 4$ as follows:

```
cointeg rank=1 j=(1, 0, 0, 0);
```

When the system contains three variables and the RANK=2 option, you can specify the restriction matrix for the test of $\alpha_{2j} = 0$ for $j = 1, 2$ as follows:

```
cointeg rank=2 j=(1 0, 0 0, 0 1);
```

NORMALIZE=variable

specifies a single dependent (endogenous) variable name whose cointegrating vectors are normalized. If the variable name is different from that specified in the COINTEST=(JOHANSEN=) or ECM= option in the MODEL statement, the variable name specified in the COINTEG statement is used. If the normalized variable is not specified, cointegrating vectors are not normalized.

RANK=number

specifies the cointegration rank of the cointegrated system. This option is required in the COINTEG statement. The rank of cointegration should be greater than zero and less than the number of dependent (endogenous) variables. If the value of the RANK= option in the COINTEG statement is different from that specified in the ECM= option, the rank specified in the COINTEG statement is used.

ID Statement

ID *variable* INTERVAL=*value* < ALIGN=*value* > ;

The ID statement specifies a variable that identifies observations in the input data set. The datetime variable specified in the ID statement is included in the OUT= data set if the OUTPUT statement is specified. Note that the ID *variable* is usually a SAS datetime variable. The values of the ID variable are extrapolated for the forecast observations based on the value of the INTERVAL= option.

ALIGN=value

controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. The default is BEGINNING. The ALIGN= option is used to align the ID variable to the beginning, middle, or end of the time ID interval specified by the INTERVAL= option.

INTERVAL=value

specifies the time interval between observations. This option is required in the ID statement. The INTERVAL= option is used in conjunction with the ID variable to check that the input data are in order and have no missing periods. The INTERVAL= option is also used to extrapolate the ID values past the end of the input data when the OUTPUT statement is specified.

The following is an example of the ID statement:

```
proc varmax data=one;
  id date interval=qtr align=mid;
  model y1-y3 / p=1;
run;
```

MODEL Statement

MODEL *dependents* < = *regressors* >
 < , *dependents* < = *regressors* > ... >
 < / *options* > ;

The MODEL statement specifies dependent (endogenous) variables and independent (exogenous) variables for the VARMAX model. The multivariate model can have the same or different independent variables corresponding to the dependent variables. As a special case, the VARMAX procedure allows you to analyze one dependent variable. Only one MODEL statement is allowed.

For example, the following statements are equivalent ways of specifying the multivariate model for the vector (y_1, y_2, y_3) :

```
model y1 y2 y3 </options>;
model y1-y3 </options>;
```

The following statements are equivalent ways of specifying the multivariate model with independent variables, where y_1, y_2, y_3 , and y_4 are the dependent variables and x_1, x_2, x_3, x_4 , and x_5 are the independent variables:

```
model y1 y2 y3 y4 = x1 x2 x3 x4 x5 </options>;
model y1 y2 y3 y4 = x1-x5 </options>;
model y1 = x1-x5, y2 = x1-x5, y3 y4 = x1-x5 </options>;
model y1-y4 = x1-x5 </options>;
```

When the multivariate model has different independent variables that correspond to each of the dependent variables, equations are separated by commas (,) and the model can be specified as illustrated by the following MODEL statement:

```
model y1 = x1-x3, y2 = x3-x5, y3 y4 = x1-x5 </options>;
```

The following options can be used in the MODEL statement after a forward slash (/):

CENTER

centers the dependent (endogenous) variables by subtracting their means. Note that centering is done after differencing when the DIF= or DIFY= option is specified. If there are exogenous (independent) variables, this option is not applicable.

```
model y1 y2 / p=1 center;
```

DIF(variable (number-list) <... variable (number-list) >)

DIF=(variable (number-list) <... variable (number-list) >)

specifies the degrees of differencing to be applied to the specified dependent or independent variables. The *number-list* must contain one or more numbers, each of which should be greater than zero. The differencing can be the same for all variables, or it can vary among variables. For example, the DIF=($y_1(1,4)$ $y_3(1)$ $x_2(2)$) option specifies that the series y_1 is differenced at lag 1 and at lag 4, which is

$$(1 - B^4)(1 - B)y_{1t} = (y_{1t} - y_{1,t-1}) - (y_{1,t-4} - y_{1,t-5})$$

the series y_3 is differenced at lag 1, which is $(y_{3t} - y_{3,t-1})$; and the series x_2 is differenced at lag 2, which is $(x_{2t} - x_{2,t-2})$.

The following uses the data dy_1 , y_2 , x_1 , and dx_2 , where $dy_1 = (1 - B)y_{1t}$ and $dx_2 = (1 - B)^2x_{2t}$.

```
model y1 y2 = x1 x2 / p=1 dif=(y1(1) x2(2));
```

DIFX(number-list)**DIFX=(number-list)**

specifies the degrees of differencing to be applied to all independent variables. The *number-list* must contain one or more numbers, each of which should be greater than zero. For example, the DIFX=(1) option specifies that all of the independent series are differenced once at lag 1. The DIFX=(1,4) option specifies that all of the independent series are differenced at lag 1 and at lag 4. If independent variables are specified in the DIF= option, then the DIFX= option is ignored.

The following statement uses the data y_1 , y_2 , dx_1 , and dx_2 , where $dx_1 = (1 - B)x_{1t}$ and $dx_2 = (1 - B)x_{2t}$.

```
model y1 y2 = x1 x2 / p=1 difx(1);
```

DIFY(number-list)**DIFY=(number-list)**

specifies the degrees of differencing to be applied to all dependent (endogenous) variables. The *number-list* must contain one or more numbers, each of which should be greater than zero. For details, see the DIFX= option. If dependent variables are specified in the DIF= option, then the DIFY= option is ignored.

```
model y1 y2 / p=1 dify(1);
```

METHOD=value

requests the type of estimates to be computed. The possible values of the METHOD= option are as follows:

- | | |
|----|---|
| LS | specifies least squares estimates. |
| ML | specifies maximum likelihood estimates. |

When the ECM=, PRIOR=, and Q= options and the GARCH statement are specified, the default ML method is used regardless of the method given by the METHOD= option.

```
model y1 y2 / p=1 method=ml;
```

NOCURRENTX

suppresses the current values x_t of the independent variables. In general, the VARX(p, s) model is

$$y_t = \delta + \sum_{i=1}^p \Phi_i y_{t-i} + \sum_{i=0}^s \Theta_i^* x_{t-i} + \epsilon_t$$

where p is the number of lags of the dependent variables included in the model, and s is the number of lags of the independent variables included in the model, including the contemporaneous values of x_t .

A VARX(1,2) model can be specified as:

```
model y1 y2 = x1 x2 / p=1 xlag=2;
```

If the NOCURRENTX option is specified, it suppresses the current values \mathbf{x}_t and starts with \mathbf{x}_{t-1} . The VARX(p, s) model is redefined as:

$$y_t = \delta + \sum_{i=1}^p \Phi_i y_{t-i} + \sum_{i=1}^s \Theta_i^* x_{t-i} + \epsilon_t$$

This model with $p = 1$ and $s = 2$ can be specified as:

```
model y1 y2 = x1 x2 / p=1 xlag=2 nocurrentx;
```

NOINT

suppresses the intercept parameter δ .

```
model y1 y2 / p=1 noint;
```

NSEASON=*number*

specifies the number of seasonal periods. When the NSEASON=*number* option is specified, (*number* - 1) seasonal dummies are added to the regressors. If the NOINT option is specified, the NSEASON= option is not applicable.

```
model y1 y2 / p=1 nseason=4;
```

SCENTER

centers seasonal dummies specified by the NSEASON= option. The centered seasonal dummies are generated by $c - (1/s)$, where c is a seasonal dummy generated by the NSEASON= s option.

```
model y1 y2 / p=1 nseason=4 scenter;
```

TREND=*value*

specifies the degree of deterministic time trend included in the model. Valid values are as follows:

LINEAR includes a linear time trend as a regressor.

QUAD includes linear and quadratic time trends as regressors.

The TREND=QUAD option is not applicable for a cointegration analysis.

```
model y1 y2 / p=1 trend=linear;
```

VARDEF=*value*

corrects for the degrees of freedom of the denominator for computing an error covariance matrix for the METHOD=LS option. If the METHOD=ML option is specified, the VARDEF=N option is always used. Valid values are as follows:

DF	specifies that the number of nonmissing observation minus the number of regressors be used.
N	specifies that the number of nonmissing observation be used.

```
model y1 y2 / p=1 vardef=n;
```

Printing Control Options

LAGMAX=*number*

specifies the maximum number of lags for which results are computed and displayed by the PRINT=(CORRX CORRY COVX COVY IARR IMPULSE= IMPULSX= PARCOEF PCANCORR PCORR) options. This option is also used to limit the printed results for the cross covariances and cross-correlations of residuals. The default is LAGMAX=min(12, $T-2$), where T is the number of nonmissing observations.

```
model y1 y2 / p=1 lagmax=6;
```

NOPRINT

suppresses all printed output.

```
model y1 y2 / p=1 noprint;
```

PRINTALL

requests all printing control options. The options set by the option PRINTALL are DFTEST=, MINIC=, PRINTFORM=BOTH, and PRINT=(CORRB CORRX CORRY COVB COVE COVX COVY DECOMPOSE DYNAMIC IARR IMPULSE=(ALL) IMPULSX=(ALL) PARCOEF PCANCORR PCORR ROOTS YW).

You can also specify this option as the option ALL.

```
model y1 y2 / p=1 printall;
```

PRINTFORM=*value*

requests the printing format of the output generated by the PRINT= option and cross covariances and cross-correlations of residuals. Valid values are as follows:

BOTH	prints output in both MATRIX and UNIVARIATE forms.
MATRIX	prints output in matrix form. This is the default.
UNIVARIATE	prints output by variables.

```
model y1 y2 / p=1 print=(impulse) printform=univariate;
```

Printing Options

PRINT=(options)

The following options can be used in the PRINT=() option. The options are listed within parentheses. If a number in parentheses follows an option listed below, then the option prints the number of lags specified by *number* in parentheses. The default is the number of lags specified by the LAGMAX=*number* option.

CORRB

prints the estimated correlations of the parameter estimates.

CORRX

CORRX(number)

prints the cross-correlation matrices of exogenous (independent) variables. The *number* should be greater than zero.

CORRY

CORRY(number)

prints the cross-correlation matrices of dependent (endogenous) variables. The *number* should be greater than zero.

COVB

prints the estimated covariances of the parameter estimates.

COVPE

COVPE(number)

prints the covariance matrices of *number*-ahead prediction errors for the VARMAX(*p,q,s*) model. The *number* should be greater than zero. If the DIF= or DIFY= option is specified, the covariance matrices of multistep prediction errors are computed based on the differenced data. This option is not applicable when the PRIOR= option is specified. See the section “Forecasting” on page 2122 for details.

COVX

COVX(number)

prints the cross-covariance matrices of exogenous (independent) variables. The *number* should be greater than zero.

COVY

COVY(number)

prints the cross-covariance matrices of dependent (endogenous) variables. The *number* should be greater than zero.

DECOMPOSE

DECOMPOSE(number)

prints the decomposition of the prediction error covariances using up to the number of lags specified by *number* in parentheses for the VARMA(*p,q*) model. The *number* should be greater than zero. It can be interpreted as the contribution of innovations in one variable to the

mean squared error of the multistep forecast of another variable. The DECOMPOSE option also prints proportions of the forecast error variance.

If the DIF= or DIFY= option is specified, the covariance matrices of multistep prediction errors are computed based on the differenced data. This option is not applicable when the PRIOR= option is specified. See the section “[Forecasting](#)” on page 2122 for details.

DIAGNOSE

prints the residual diagnostics and model diagnostics.

DYNAMIC

prints the contemporaneous relationships among the components of the vector time series.

ESTIMATES

prints the coefficient estimates and a schematic representation of the significance and sign of the parameter estimates.

IARR

IARR(*number*)

prints the infinite order AR representation of a VARMA process. The *number* should be greater than zero. If the ECM= option and the COINTEG statement are specified, then the reparameterized AR coefficient matrices are printed.

IMPULSE

IMPULSE(*number*)

IMPULSE=(SIMPLE ACCUM ORTH STDERR ALL)

IMPULSE(*number*)=(SIMPLE ACCUM ORTH STDERR ALL)

prints the impulse response function. The *number* should be greater than zero. It investigates the response of one variable to an impulse in another variable in a system that involves a number of other variables as well. It is an infinite order MA representation of a VARMA process. See the section “[Impulse Response Function](#)” on page 2111 for details.

The following options can be used in the IMPULSE=() option. The options are specified within parentheses.

ACCUM	prints the accumulated impulse response function.
ALL	is equivalent to specifying all of SIMPLE, ACCUM, ORTH, and STDERR.
ORTH	prints the orthogonalized impulse response function.
SIMPLE	prints the impulse response function. This is the default.
STDERR	prints the standard errors of the impulse response function, the accumulated impulse response function, or the orthogonalized impulse response function.

If the exogenous variables are used to fit the model, then the STDERR option is ignored.

IMPULSX**IMPULSX(number)****IMPULSX=(SIMPLE ACCUM ALL)****IMPULSX(number)=(SIMPLE ACCUM ALL)**

prints the impulse response function related to exogenous (independent) variables. The *number* should be greater than zero. See the section “[Impulse Response Function](#)” on page 2111 for details.

The following options can be used in the IMPULSX=() option. The options are specified within parentheses.

ACCUM	prints the accumulated impulse response matrices for the transfer function.
ALL	is equivalent to specifying both SIMPLE and ACCUM.
SIMPLE	prints the impulse response matrices for the transfer function. This is the default.

PARCOEF**PARCOEF(number)**

prints the partial autoregression coefficient matrices, Φ_{mm} up to the lag *number*. The *number* should be greater than zero. With a VAR process, this option is useful for the identification of the order since the Φ_{mm} have the property that they equal zero for $m > p$ under the hypothetical assumption of a VAR(p) model. See the section “[Tentative Order Selection](#)” on page 2127 for details.

PCANCORR**PCANCORR(number)**

prints the partial canonical correlations of the process at lag m and the test for testing $\Phi_m=0$ for $m > p$ up to the lag *number*. The *number* should be greater than zero. The lag m partial canonical correlations are the canonical correlations between \mathbf{y}_t and \mathbf{y}_{t-m} , after adjustment for the dependence of these variables on the intervening values $\mathbf{y}_{t-1}, \dots, \mathbf{y}_{t-m+1}$. See the section “[Tentative Order Selection](#)” on page 2127 for details.

PCORR**PCORR(number)**

prints the partial correlation matrices. The *number* should be greater than zero. With a VAR process, this option is useful for a tentative order selection by the same property as the partial autoregression coefficient matrices, as described in the PRINT=(PARCOEF) option. See the section “[Tentative Order Selection](#)” on page 2127 for details.

ROOTS

prints the eigenvalues of the $kp \times kp$ companion matrix associated with the AR characteristic function $\Phi(B)$, where k is the number of dependent (endogenous) variables, and $\Phi(B)$ is the finite order matrix polynomial in the backshift operator B , such that $B^i \mathbf{y}_t = \mathbf{y}_{t-i}$. These eigenvalues indicate the stationary condition of the process since the stationary condition on the roots of $|\Phi(B)| = 0$ in the VAR(p) model is equivalent to the condition in the corresponding VAR(1) representation that all eigenvalues of the companion matrix be less than one in absolute value. Similarly, you can use this option to check the invertibility of the MA process. In

addition, when the GARCH statement is specified, this option prints the roots of the GARCH characteristic polynomials to check covariance stationarity for the GARCH process.

YW

prints Yule-Walker estimates of the preliminary autoregressive model for the dependent (endogenous) variables. The coefficient matrices are printed using the maximum order of the autoregressive process.

Some examples of the PRINT= option are as follows:

```
model y1 y2 / p=1 print=(covy(10) corry(10));
model y1 y2 / p=1 print=(parcoef pcancorr pcorr);
model y1 y2 / p=1 print=(impulse(8) decompose(6) covpe(6));
model y1 y2 / p=1 print=(dynamic roots yw);
```

Lag Specification Options

P=number

P=(number-list)

specifies the order of the vector autoregressive process. Subset models of vector autoregressive orders can be specified by listing the desired set of lags. For example, you can specify the P=(1,3,4) option. The P=3 option is equivalent to the P=(1,2,3) option. The default is P=0.

If P=0 and there are no exogenous (independent) variables, then the AR polynomial order is automatically determined by minimizing an information criterion. If P=0 and the PRIOR= or ECM= option or both are specified, then the AR polynomial order is determined automatically.

If the ECM= option is specified, then subset models of vector autoregressive orders are not allowed and the AR maximum order specified is used.

Examples illustrating the P= option follow:

```
model y1 y2 / p=3;
model y1 y2 / p=(1,3);
model y1 y2 / p=(1,3) prior;
```

Q=number

Q=(number-list)

specifies the order of the moving-average error process. Subset models of moving-average orders can be specified by listing the desired set of lags. For example, you can specify the Q=(1,5) option. The default is Q=0.

```
model y1 y2 / p=1 q=1;
model y1 y2 / q=(2);
```

XLAG=number**XLAG=(number-list)**

specifies the lags of exogenous (independent) variables. Subset models of distributed lags can be specified by listing the desired set of lags. For example, XLAG=(2) selects only a lag 2 of the exogenous variables. The default is XLAG=0. To exclude the present values of exogenous variables from the model, the NOCURRENTX option must be used.

```
model y1 y2 = x1-x3 / xlag=2 nocurrentx;
model y1 y2 = x1-x3 / p=1 xlag=(2);
```

Tentative Order Selection Options**MINIC****MINIC=(TYPE=value P=number Q=number PERROR=number)**

prints the information criterion for the appropriate AR and MA tentative order selection and for the diagnostic checks of the fitted model.

If the MINIC= option is not specified, all types of information criteria are printed for diagnostic checks of the fitted model.

The following options can be used in the MINIC=() option. The options are specified within parentheses.

P=number**P=($p_{min}:p_{max}$)**

specifies the range of AR orders to be considered in the tentative order selection. The default is P=(0:5). The P=3 option is equivalent to the P=(0:3) option.

PERROR=number**PERROR=($p_{\epsilon,min}:p_{\epsilon,max}$)**

specifies the range of AR orders for obtaining the error series. The default is PERROR=($p_{max} : p_{max} + q_{max}$).

Q=number**Q=($q_{min}:q_{max}$)**

specifies the range of MA orders to be considered in the tentative order selection. The default is Q=(0:5).

TYPE=value

specifies the criterion for the model order selection. Valid criteria are as follows:

AIC	specifies the Akaike information criterion.
AICC	specifies the corrected Akaike information criterion. This is the default criterion.
FPE	specifies the final prediction error criterion.
HQC	specifies the Hanna-Quinn criterion.

SBC specifies the Schwarz Bayesian criterion. You can also specify this value as TYPE=BIC.

```
model y1 y2 / minic;
model y1 y2 / minic=(type=aic p=5);
```

Cointegration Related Options

Two options are related to integrated time series; one is the DFTEST option to test for a unit root and the other is the COINTTEST option to test for cointegration.

DFTEST

DFTEST=(DLAG=*number*)

DFTEST=(DLAG=(*number*) ... (*number*))

prints the Dickey-Fuller unit root tests. The DLAG=(*number*) ... (*number*) option specifies the regular or seasonal unit root test. Supported values of *number* are in 1, 2, 4, 12. If the *number* is greater than one, a seasonal Dickey-Fuller test is performed. If the TREND= option is specified, the seasonal unit root test is not available. The default is DLAG=1.

For example, the DFTEST=(DLAG=(1)(12)) option produces two tables: the Dickey-Fuller regular unit root test and the seasonal unit root test.

Some examples of the DFTEST= option follow:

```
model y1 y2 / p=2 dfctest;
model y1 y2 / p=2 dfctest=(dlag=4);
model y1 y2 / p=2 dfctest=(dlag=(1)(12));
model y1 y2 / p=2 dfctest cointtest;
```

COINTTEST

COINTTEST=(JOHANSEN < (=options) > SW < (=options) > SIGLEVEL=*number*)

The following options can be used with the COINTTEST=() option. The options are specified within parentheses.

JOHANSEN

JOHANSEN=(TYPE=*value* IORDER=*number* NORMALIZE=*variable*)

prints the cointegration rank test for multivariate time series based on Johansen's method. This test is provided when the number of dependent (endogenous) variables is less than or equal to 11. See the section "Vector Error Correction Modeling" on page 2153 for details.

The VARX(*p,s*) model can be written as the error correction model

$$\Delta \mathbf{y}_t = \Pi \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + A D_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

where Π , Φ_i^* , A , and Θ_i^* are coefficient parameters; D_t is a deterministic term such as a constant, a linear trend, or seasonal dummies.

The $I(1)$ model is defined by one reduced-rank condition. If the cointegration rank is $r < k$, then there exist $k \times r$ matrices α and β of rank r such that $\Pi = \alpha\beta'$.

The $I(1)$ model is rewritten as the $I(2)$ model

$$\Delta^2 \mathbf{y}_t = \Pi \mathbf{y}_{t-1} - \Psi \Delta \mathbf{y}_{t-1} + \sum_{i=1}^{p-2} \Psi_i \Delta^2 \mathbf{y}_{t-i} + AD_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \epsilon_t$$

where $\Psi = I_k - \sum_{i=1}^{p-1} \Phi_i^*$ and $\Psi_i = -\sum_{j=i+1}^{p-1} \Phi_j^*$.

The $I(2)$ model is defined by two reduced-rank conditions. One is that $\Pi = \alpha\beta'$, where α and β are $k \times r$ matrices of full-rank r . The other is that $\alpha'_{\perp} \Psi \beta_{\perp} = \xi \eta'$ where ξ and η are $(k-r) \times s$ matrices with $s \leq k-r$; α_{\perp} and β_{\perp} are $k \times (k-r)$ matrices of full-rank $k-r$ such that $\alpha' \alpha_{\perp} = 0$ and $\beta' \beta_{\perp} = 0$.

The following options can be used in the JOHANSEN=() option. The options are specified within parentheses.

IORDER=*number* specifies the integrated order.

IORDER=1 prints the cointegration rank test for an integrated order 1 and prints the long-run parameter, β , and the adjustment coefficient, α . This is the default. If the IORDER=1 option is specified, then the AR order should be greater than or equal to 1. When the P=0 option, the value of P is set to 1 for the Johansen test.

IORDER=2 prints the cointegration rank test for integrated orders 1 and 2. If the IORDER=2 option is specified, then the AR order should be greater than or equal to 2. If the P=1 option with the IORDER=2 option, then the value of IORDER is set to 1; if the P=0 option with the IORDER=2 option, then the value of P is set to 2.

NORMALIZE=*variable* specifies the dependent (endogenous) variable name whose cointegration vectors are to be normalized. If the normalized variable is different from that specified in the ECM= option or the COINTEG statement, then the value specified in the COINTEG statement is used.

TYPE=*value* specifies the type of cointegration rank test to be printed. Valid values are as follows:

MAX prints the cointegration maximum eigenvalue test.

TRACE prints the cointegration trace test. This is the default.

If the NOINT option is not specified, the procedure prints two different cointegration rank tests in the presence of the unrestricted and restricted deterministic terms (constant or linear trend) models. If the IORDER=2 option is specified, the procedure automatically determines that the TYPE=TRACE option.

Some examples illustrating the COINTTEST= option follow:

```

model y1 y2 / p=2 cointtest=(johansen=(type=max normalize=y1));
model y1 y2 / p=2 cointtest=(johansen=(iorder=2 normalize=y1));

```

SIGLEVEL=*value*

sets the size of cointegration rank tests and common trends tests.

The SIGLEVEL=*value* can be set to 0.1, 0.05, or 0.01. The default is SIGLEVEL=0.05.

```

model y1 y2 / p=2 cointtest=(johansen siglevel=0.1);
model y1 y2 / p=2 cointtest=(sw siglevel=0.1);

```

SW**SW=(TYPE=*value* LAG=*number*)**

prints common trends tests for a multivariate time series based on the Stock-Watson method. This test is provided when the number of dependent (endogenous) variables is less than or equal to 6. See the section “Common Trends” on page 2150 for details.

The following options can be used in the SW=() option. The options are listed within parentheses.

LAG=*number* specifies the number of lags. The default is $LAG = \max(1, p)$ for the TYPE=FILTDIF or TYPE=FILTRES option, where p is the AR maximum order specified by the P= option; $LAG = T^{1/4}$ for the TYPE=KERNEL option, where T is the number of nonmissing observations. If the specified LAG=*number* exceeds the default, then it is replaced by the default.

TYPE=*value* specifies the type of common trends test to be printed. Valid values are as follows:

FILTDIF	prints the common trends test based on the filtering method applied to the differenced series. This is the default.
FILTRES	prints the common trends test based on the filtering method applied to the residual series.
KERNEL	prints the common trends test based on the kernel method.

```

model y1 y2 / p=2 cointtest=(sw);
model y1 y2 / p=2 cointtest=(sw=(type=kernel));
model y1 y2 / p=2 cointtest=(sw=(type=kernel lag=3));

```

Bayesian VARX Estimation Options**PRIOR****PRIOR=(*prior-options*)**

specifies the prior value of parameters for the BVARX(p, s) model. The BVARX model allows for a subset model specification. If the ECM= option is specified with the PRIOR option, the BVECMX(p, s) form is fitted. To compute the standard errors of the forecasts, a bootstrap

procedure is used. See the section “[Bayesian VAR and VARX Modeling](#)” on page 2139 for details.

The following options can be used with the PRIOR=(*prior-options*) option. The *prior-options* are listed within parentheses.

IVAR

IVAR=(*variables*)

specifies an integrated BVAR(p) model. The *variables* should be specified in the MODEL statement as dependent variables. If you use the IVAR option without *variables*, then it sets the overall prior mean of the first lag of each variable equal to one in its own equation and sets all other coefficients to zero. If *variables* are specified, it sets the prior mean of the first lag of the specified variables equal to one in its own equation and sets all other coefficients to zero. When the series $\mathbf{y}_t = (y_1, y_2)'$ follows a bivariate BVAR(2) process, the IVAR or IVAR=($y_1 \ y_2$) option is equivalent to specifying MEAN=(1 0 0 0 0 1 0 0).

If the PRIOR=(MEAN=) or ECM= option is specified, the IVAR= option is ignored.

LAMBDA=*value*

specifies the prior standard deviation of the AR coefficient parameter matrices. It should be a positive number. The default is LAMBDA=1. As the value of the LAMBDA= option is increased, the BVAR(p) model becomes closer to a VAR(p) model.

MEAN=(*vector*)

specifies the mean vector in the prior distribution for the AR coefficients. If the vector is not specified, the prior value is assumed to be a zero vector. See the section “[Bayesian VAR and VARX Modeling](#)” on page 2139 for details.

You can specify the mean vector by order of the equation. Let $(\delta, \Phi_1, \dots, \Phi_p)$ be the parameter sets to be estimated and $\Phi = (\Phi_1, \dots, \Phi_p)$ be the AR parameter sets. The mean vector is specified by row-wise from Φ ; that is, the MEAN=(vec(Φ')) option.

For the PRIOR=(mean) option in the BVAR(2),

$$\Phi = \begin{pmatrix} \phi_{1,11} & \phi_{1,12} & \phi_{2,11} & \phi_{2,12} \\ \phi_{1,21} & \phi_{1,22} & \phi_{2,21} & \phi_{2,22} \end{pmatrix} = \begin{pmatrix} 2 & 0.1 & 1 & 0 \\ 0.5 & 3 & 0 & -1 \end{pmatrix}$$

where $\phi_{l,ij}$ is an element of Φ , l is a lag, i is associated with the first dependent variable, and j is associated with the second dependent variable.

```
model y1 y2 / p=2 prior=(mean=(2 0.1 1 0 0.5 3 0 -1));
```

The deterministic terms and exogenous variables are considered to shrink toward zero; you must omit prior means of exogenous variables and deterministic terms such as a constant, seasonal dummies, or trends.

For a Bayesian error correction model estimated when both the ECM= and PRIOR= options are used, a mean vector for only lagged AR coefficients, Φ_i^* , in terms of regressors $\Delta \mathbf{y}_{t-i}$, for

$i = 1, \dots, (p - 1)$ is used in the VECM(p) representation. The diffused prior variance of α is used, since β is replaced by $\hat{\beta}$ estimated in a nonconstrained VECM(p) form.

$$\Delta \mathbf{y}_t = \alpha \mathbf{z}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + A D_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \epsilon_t$$

where $\mathbf{z}_t = \beta' \mathbf{y}_t$.

For example, in the case of a bivariate ($k = 2$) BVECM(2) form, the option

$$\text{MEAN} = (\phi_{1,11}^* \phi_{1,12}^* \phi_{1,21}^* \phi_{1,22}^*)$$

where $\phi_{1,ij}^*$ is the (i, j) th element of the matrix Φ_1^* .

NREP=number

specifies the number of periods to compute the measure of forecast accuracy. The default is NREP=0.5 T , where T is the number of observations.

THETA=value

specifies the prior standard deviation of the AR coefficient parameter matrices. The *value* is in the interval (0,1). The default is THETA=0.1. As the value of the THETA= option approaches 1, the specified BVAR(p) model approaches a VAR(p) model.

Some examples of the PRIOR= option follow:

```
model y1 y2 / p=2 prior;
model y1 y2 / p=2 prior=(theta=0.2 lambda=5);
model y1 y2 = x1 / p=2 prior=(theta=0.2 lambda=5);
model y1 y2 = x1 / p=2
    prior=(theta=0.2 lambda=5 mean=(2 0.1 1 0 0.5 3 0 -1));
```

See the section “Bayesian VAR and VARX Modeling” on page 2139 for details.

Vector Error Correction Model Options

ECM=(RANK=number NORMALIZE= emphvariable ECTREND)

specifies a vector error correction model.

The following options can be used in the ECM=() option. The options are specified within parentheses.

NORMALIZE=variable

specifies a single dependent variable name whose cointegrating vectors are normalized. If the variable name is different from that specified in the COINTEG statement, then the value specified in the COINTEG statement is used.

RANK=number

specifies the cointegration rank. This option is required in the ECM= option. The value of the RANK= option should be greater than zero and less than or equal to the number of dependent (endogenous) variables, k . If the rank is different from that specified in the COINTEG statement, then the value specified in the COINTEG statement is used.

ECTREND

specifies the restriction on the drift in the VECM(p) form.

- There is no separate drift in the VECM(p) form, but a constant enters only through the error correction term.

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha}(\boldsymbol{\beta}', \beta_0)(\mathbf{y}'_{t-1}, 1)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

An example of the ECTREND option follows:

```
model y1 y2 / p=2 ecm=(rank=1 ectrend);
```

- There is a separate drift and no separate linear trend in the VECM(p) form, but a linear trend enters only through the error correction term.

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha}(\boldsymbol{\beta}', \beta_1)(\mathbf{y}'_{t-1}, t)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\delta}_0 + \boldsymbol{\epsilon}_t$$

An example of the ECTREND option with the TREND= option follows:

```
model y1 y2 / p=2 ecm=(rank=1 ectrend) trend=linear;
```

If the NSEASON option is specified, then the NSEASON option is ignored; if the NOINT option is specified, then the ECTREND option is ignored.

Some examples of the ECM= option follow:

```
model y1 y2 / p=2 ecm=(rank=1 normalized=y1);
model y1 y2 / p=2 ecm=(rank=1 ectrend) trend=linear;
```

See the section “[Vector Error Correction Modeling](#)” on page 2153 for details.

GARCH Statement

GARCH options ;

The GARCH statement specifies a GARCH-type multivariate conditional heteroscedasticity model.

The following options can be used in the GARCH statement.

FORM=value

specifies the representation for a GARCH model. Valid values are as follows:

BEKK specifies a *BEKK* representation. This is the default.

CCC specifies a constant conditional correlation representation.

OUTHT=SAS-data-set

writes the conditional covariance matrix to an output data set.

P=number**P=(number-list)**

specifies the order of the process or the subset of GARCH terms to be fitted. For example, you can specify the P=(1,3) option. The P=3 option is equivalent to the P=(1,2,3) option. The default is P=0.

Q=number**Q=(number-list)**

specifies the order of the process or the subset of ARCH terms to be fitted. This option is required in the GARCH statement. For example, you can specify the Q=(2) option. The Q=2 option is equivalent to the Q=(1,2) option.

For the VAR(1)–ARCH(1) model,

```
model y1 y2 / p=1;
garch q=1 form=bekk;
```

For the multivariate GARCH(1,1) model,

```
model y1 y2;
garch q=1 p=1 form=ccc;
```

Other multivariate GARCH-type models are

```
model y1 y2 = x1 / xlag=1;
garch q=1;
```

```
model y1 y2 / q=1;
garch q=1 p=1;
```

See the section “[Multivariate GARCH Modeling](#)” on page 2172 for details.

NLOPTIONS Statement

NLOPTIONS *options* ;

The VARMAX procedure uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. For a list of all the options of the NLOPTIONS statement, see Chapter 6, “[Nonlinear Optimization Methods](#).”

An example of the NLOPTIONS statement follows:

```
proc varmax data=one;
  nloptions tech=qn;
  model y1 y2 / p=2;
run;
```

The VARMAX procedure uses the dual quasi-Newton optimization method by default when no NLOPTIONS statement is specified. However, it uses Newton-Raphson ridge optimization when the NLOPTIONS statement is specified.

The following example uses the TECH=QUANEW by default.

```
proc varmax data=one;
  model y1 y2 / p=2 method=ml;
run;
```

The next example uses the TECH=NRRIDG by default.

```
proc varmax data=one;
  nloptions maxiter=500 maxfunc=5000;
  model y1 y2 / p=2 method=ml;
run;
```

OUTPUT Statement

OUTPUT < options > ;

The OUTPUT statement generates and prints forecasts based on the model estimated in the previous MODEL statement and, optionally, creates an output SAS data set that contains these forecasts.

When the GARCH model is estimated, the upper and lower confidence limits of forecasts are calculated by assuming that the error covariance has homoscedastic conditional covariance.

ALPHA=number

sets the forecast confidence limit size, where *number* is between 0 and 1. When you specify the ALPHA=*number* option, the upper and lower confidence limits define the $100(1 - \alpha)\%$ confidence interval. The default is ALPHA=0.05, which produces 95% confidence intervals.

BACK=number

specifies the number of observations before the end of the data at which the multistep forecasts begin. The BACK= option value must be less than or equal to the number of observations minus the number of lagged regressors in the model. The default is BACK=0, which means that the forecasts start at the end of the available data.

LEAD=number

specifies the number of multistep forecast values to compute. The default is LEAD=12.

NOPRINT

suppresses the printed forecast values of each dependent (endogenous) variable.

OUT=SAS-data-set

writes the forecast values to an output data set.

Some examples of the OUTPUT statements follow:

```

proc varmax data=one;
  model y1 y2 / p=2;
  output lead=6 back=2;
run;

proc varmax data=one;
  model y1 y2 / p=2;
  output out=for noprint;
run;

```

RESTRICT Statement

RESTRICT *restriction, . . . , restriction* ;

The RESTRICT statement restricts the specified parameters to the specified values. Only one RESTRICT statement is allowed, but multiple restrictions can be specified in one RESTRICT statement.

The *restriction*'s form is *parameter=value* and each restriction is separated by commas. Parameters are referred by the following keywords:

- CONST(*i*) is the intercept parameter of the *i*th time series y_{it}
- AR(*l, i, j*) is the autoregressive parameter of the lag *l* value of the *j*th dependent (endogenous) variable, $y_{j,t-l}$, to the *i*th dependent variable at time *t*, y_{it}
- MA(*l, i, j*) is the moving-average parameter of the lag *l* value of the *j*th error process, $\epsilon_{j,t-l}$, to the *i*th dependent variable at time *t*, y_{it}
- XL(*l, i, j*) is the exogenous parameter of the lag *l* value of the *j*th exogenous (independent) variable, $x_{j,t-l}$, to the *i*th dependent variable at time *t*, y_{it}
- SDUMMY(*i, j*) is the *j*th seasonal dummy of the *i*th time series at time *t*, y_{it} , where $j = 1, \dots, (nseason - 1)$, where *nseason* is based on the NSEASON= option in the MODEL statement
- LTREND(*i*) is the linear trend parameter of the current value *i*th time series y_{it}
- QTREND(*i*) is the quadratic trend parameter of the current value *i*th time series y_{it}

The following keywords are for the fitted GARCH model. The indexes *i* and *j* refer to the position of the element in the coefficient matrix.

- GCHC(*i, j*) is the constant parameter of the covariance matrix, H_t , and (*i, j*) is $1 \leq i = j \leq k$ for CCC representation and $1 \leq i \leq j \leq k$ for BEKK representations, where *k* is the number of dependent variables
- ACH(*l, i, j*) is the ARCH parameter of the lag *l* value of $\epsilon_t \epsilon_t'$, where $i, j = 1, \dots, k$ for BEKK representation and $i = j = 1, \dots, k$ for CCC representation

- $GCH(l,i,j)$ is the GARCH parameter of the lag l value of covariance matrix, H_t , where $i, j = 1, \dots, k$ for *BEKK* representation and $i = j = 1, \dots, k$ for *CCC* representation
- $CCC(i,j)$ is the constant conditional correlation parameter for only the *CCC* representation; (i,j) is $1 \leq i < j \leq k$

To use the **RESTRICT** statement, you need to know the form of the model. If the **P=**, **Q=**, and **XLAG=** options are not specified, then the **RESTRICT** statement is not applicable.

Restricted parameter estimates are computed by introducing a Lagrangian parameter for each restriction (Pringle and Rayner 1971). The Lagrangian parameter measures the sensitivity of the sum of square errors to the restriction. The estimates of these Lagrangian parameters and their significance are printed in the restriction results table.

The following are examples of the **RESTRICT** statement. The first example shows a bivariate ($k=2$) VAR(2) model,

```
proc varmax data=one;
  model y1 y2 / p=2;
  restrict AR(1,1,2)=0, AR(2,1,2)=0.3;
run;
```

The AR(1,1,2) and AR(2,1,2) parameters are fixed as AR(1,1,2)=0 and AR(2,1,2)=0.3, respectively, and other parameters are to be estimated.

The following shows a bivariate ($k=2$) VARX(1,1) model with three exogenous variables,

```
proc varmax data=two;
  model y1 = x1 x2, y2 = x2 x3 / p=1 xlag=1;
  restrict XL(0,1,1)=-1.2, XL(1,2,3)=0;
run;
```

The XL(0,1,1) and XL(1,2,3) parameters are fixed as XL(0,1,1)=-1.2 and XL(1,2,3)=0, respectively, and other parameters are to be estimated.

TEST Statement

TEST *restriction, ..., restriction* ;

The **TEST** statement performs the Wald test for the joint hypothesis specified in the statement. The *restriction*'s form is *parameter=value*, and each restriction is separated by commas. The *restrictions* are specified in the same manner as in the **RESTRICT** statement. See the **RESTRICT** statement for description of model parameter naming conventions used by the **RESTRICT** and **TEST** statements. Any number of **TEST** statements can be specified.

To use the **TEST** statement, you need to know the form of the model. If the **P=**, **Q=**, and **XLAG=** options are not specified, then the **TEST** statement is not applicable.

See the section “Granger Causality Test” on page 2136 for the Wald test.

The following is an example of the TEST statement. In the case of a bivariate ($k=2$) VAR(2) model,

```
proc varmax data=one;
  model y1 y2 / p=2;
  test AR(1,1,2)=0, AR(2,1,2)=0;
run;
```

After estimating the parameters, the TEST statement tests the null hypothesis that $AR(1,1,2)=0$ and $AR(2,1,2)=0$.

Details: VARMAX Procedure

Missing Values

The VARMAX procedure currently does not support missing values. The procedure uses the first contiguous group of observations with no missing values for any of the MODEL statement variables. Observations at the beginning of the data set with missing values for any MODEL statement variables are not used or included in the output data set. At the end of the data set, observations can have dependent (endogenous) variables with missing values and independent (exogenous) variables with nonmissing values.

VARMAX Model

The vector autoregressive moving-average model with exogenous variables is called the VARMAX(p,q,s) model. The form of the model can be written as

$$\mathbf{y}_t = \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t - \sum_{i=1}^q \Theta_i \boldsymbol{\epsilon}_{t-i}$$

where the output variables of interest, $\mathbf{y}_t = (y_{1t}, \dots, y_{kt})'$, can be influenced by other input variables, $\mathbf{x}_t = (x_{1t}, \dots, x_{rt})'$, which are determined outside of the system of interest. The variables \mathbf{y}_t are referred to as dependent, response, or endogenous variables, and the variables \mathbf{x}_t are referred to as independent, input, predictor, regressor, or exogenous variables. The unobserved noise variables, $\boldsymbol{\epsilon}_t = (\epsilon_{1t}, \dots, \epsilon_{kt})'$, are a vector white noise process.

The VARMAX(p,q,s) model can be written

$$\Phi(B)\mathbf{y}_t = \Theta^*(B)\mathbf{x}_t + \Theta(B)\boldsymbol{\epsilon}_t$$

where

$$\begin{aligned} \Phi(B) &= I_k - \Phi_1 B - \dots - \Phi_p B^p \\ \Theta^*(B) &= \Theta_0^* + \Theta_1^* B + \dots + \Theta_s^* B^s \\ \Theta(B) &= I_k - \Theta_1 B - \dots - \Theta_q B^q \end{aligned}$$

are matrix polynomials in B in the backshift operator, such that $B^i \mathbf{y}_t = \mathbf{y}_{t-i}$, the Φ_i and Θ_i are $k \times k$ matrices, and the Θ_i^* are $k \times r$ matrices.

The following assumptions are made:

- $E(\epsilon_t) = 0$, $E(\epsilon_t \epsilon_t') = \Sigma$, which is positive-definite, and $E(\epsilon_t \epsilon_s') = 0$ for $t \neq s$.
- For stationarity and invertibility of the VARMAX process, the roots of $|\Phi(z)| = 0$ and $|\Theta(z)| = 0$ are outside the unit circle.
- The exogenous (independent) variables \mathbf{x}_t are not correlated with residuals ϵ_t , $E(\mathbf{x}_t \epsilon_t') = 0$. The exogenous variables can be stochastic or nonstochastic. When the exogenous variables are stochastic and their future values are unknown, forecasts of these future values are needed to forecast the future values of the endogenous (dependent) variables. On occasion, future values of the exogenous variables can be assumed to be known because they are deterministic variables. The VARMAX procedure assumes that the exogenous variables are nonstochastic if future values are available in the input data set. Otherwise, the exogenous variables are assumed to be stochastic and their future values are forecasted by assuming that they follow the VARMA(p,q) model, prior to forecasting the endogenous variables, where p and q are the same as in the VARMAX(p,q,s) model.

State-Space Representation

Another representation of the VARMAX(p,q,s) model is in the form of a state-variable or a state-space model, which consists of a state equation

$$\mathbf{z}_t = F \mathbf{z}_{t-1} + K \mathbf{x}_t + G \epsilon_t$$

and an observation equation

$$\mathbf{y}_t = H \mathbf{z}_t$$

where

$$\mathbf{z}_t = \begin{bmatrix} \mathbf{y}_t \\ \vdots \\ \mathbf{y}_{t-p+1} \\ \mathbf{x}_t \\ \vdots \\ \mathbf{x}_{t-s+1} \\ \epsilon_t \\ \vdots \\ \epsilon_{t-q+1} \end{bmatrix}, \quad K = \begin{bmatrix} \Theta_0^* \\ 0_{k \times r} \\ \vdots \\ 0_{k \times r} \\ I_r \\ 0_{r \times r} \\ \vdots \\ 0_{r \times r} \\ 0_{k \times r} \\ \vdots \\ 0_{k \times r} \end{bmatrix}, \quad G = \begin{bmatrix} I_k \\ 0_{k \times k} \\ \vdots \\ 0_{k \times k} \\ 0_{r \times k} \\ \vdots \\ 0_{r \times k} \\ I_{k \times k} \\ 0_{k \times k} \\ \vdots \\ 0_{k \times k} \end{bmatrix}$$

$$F = \begin{bmatrix} \Phi_1 & \cdots & \Phi_{p-1} & \Phi_p & \Theta_1^* & \cdots & \Theta_{s-1}^* & \Theta_s^* & -\Theta_1 & \cdots & -\Theta_{q-1} & -\Theta_q \\ I_k & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & I_k & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & I_r & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 & 0 & \cdots & I_r & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & I_k & 0 \end{bmatrix}$$

and

$$H = [I_k, 0_{k \times k}, \dots, 0_{k \times k}, 0_{k \times r}, \dots, 0_{k \times r}, 0_{k \times k}, \dots, 0_{k \times k}]$$

On the other hand, it is assumed that \mathbf{x}_t follows a VARMA(p, q) model

$$\mathbf{x}_t = \sum_{i=1}^p A_i \mathbf{x}_{t-i} + \mathbf{a}_t - \sum_{i=1}^q C_i \mathbf{a}_{t-i}$$

The model can also be expressed as

$$A(B)\mathbf{x}_t = C(B)\mathbf{a}_t$$

where $A(B) = I_r - A_1 B - \dots - A_p B^p$ and $C(B) = I_r - C_1 B - \dots - C_q B^q$ are matrix polynomials in B , and the A_i and C_i are $r \times r$ matrices. Without loss of generality, the AR and MA orders can be taken to be the same as the VARMAX(p, q, s) model, and \mathbf{a}_t and $\boldsymbol{\epsilon}_t$ are independent white noise processes.

Under suitable conditions such as stationarity, \mathbf{x}_t is represented by an infinite order moving-average process

$$\mathbf{x}_t = A(B)^{-1} C(B) \mathbf{a}_t = \Psi^x(B) \mathbf{a}_t = \sum_{j=0}^{\infty} \Psi_j^x \mathbf{a}_{t-j}$$

where $\Psi^x(B) = A(B)^{-1} C(B) = \sum_{j=0}^{\infty} \Psi_j^x B^j$.

The optimal minimum mean squared error (minimum MSE) i -step-ahead forecast of \mathbf{x}_{t+i} is

$$\begin{aligned} \mathbf{x}_{t+i|t} &= \sum_{j=i}^{\infty} \Psi_j^x \mathbf{a}_{t+i-j} \\ \mathbf{x}_{t+i|t+1} &= \mathbf{x}_{t+i|t} + \Psi_{i-1}^x \mathbf{a}_{t+1} \end{aligned}$$

For $i > q$,

$$\mathbf{x}_{t+i|t} = \sum_{j=1}^p A_j \mathbf{x}_{t+i-j|t}$$

The VARMAX(p, q, s) model has an absolutely convergent representation as

$$\begin{aligned} \mathbf{y}_t &= \Phi(B)^{-1}\Theta^*(B)\mathbf{x}_t + \Phi(B)^{-1}\Theta(B)\boldsymbol{\epsilon}_t \\ &= \Psi^*(B)\Psi^x(B)\mathbf{a}_t + \Phi(B)^{-1}\Theta(B)\boldsymbol{\epsilon}_t \\ &= V(B)\mathbf{a}_t + \Psi(B)\boldsymbol{\epsilon}_t \end{aligned}$$

or

$$\mathbf{y}_t = \sum_{j=0}^{\infty} V_j \mathbf{a}_{t-j} + \sum_{j=0}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t-j}$$

where $\Psi(B) = \Phi(B)^{-1}\Theta(B) = \sum_{j=0}^{\infty} \Psi_j B^j$, $\Psi^*(B) = \Phi(B)^{-1}\Theta^*(B)$, and $V(B) = \Psi^*(B)\Psi^x(B) = \sum_{j=0}^{\infty} V_j B^j$.

The optimal (minimum MSE) i -step-ahead forecast of \mathbf{y}_{t+i} is

$$\begin{aligned} \mathbf{y}_{t+i|t} &= \sum_{j=i}^{\infty} V_j \mathbf{a}_{t+i-j} + \sum_{j=i}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t+i-j} \\ \mathbf{y}_{t+i|t+1} &= \mathbf{y}_{t+i|t} + V_{i-1} \mathbf{a}_{t+1} + \Psi_{i-1} \boldsymbol{\epsilon}_{t+1} \end{aligned}$$

for $i = 1, \dots, v$ with $v = \max(p, q + 1)$. For $i > q$,

$$\begin{aligned} \mathbf{y}_{t+i|t} &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+i-j|t} + \sum_{j=0}^s \Theta_j^* \mathbf{x}_{t+i-j|t} \\ &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+i-j|t} + \Theta_0^* \mathbf{x}_{t+i|t} + \sum_{j=1}^s \Theta_j^* \mathbf{x}_{t+i-j|t} \\ &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+i-j|t} + \Theta_0^* \sum_{j=1}^p A_j \mathbf{x}_{t+i-j|t} + \sum_{j=1}^s \Theta_j^* \mathbf{x}_{t+i-j|t} \\ &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+i-j|t} + \sum_{j=1}^u (\Theta_0^* A_j + \Theta_j^*) \mathbf{x}_{t+i-j|t} \end{aligned}$$

where $u = \max(p, s)$.

Define $\Pi_j = \Theta_0^* A_j + \Theta_j^*$. For $i = v > q$ with $v = \max(p, q + 1)$, you obtain

$$\begin{aligned} \mathbf{y}_{t+v|t} &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+v-j|t} + \sum_{j=1}^u \Pi_j \mathbf{x}_{t+v-j|t} \quad \text{for } u \leq v \\ \mathbf{y}_{t+v|t} &= \sum_{j=1}^p \Phi_j \mathbf{y}_{t+v-j|t} + \sum_{j=1}^r \Pi_j \mathbf{x}_{t+v-j|t} \quad \text{for } u > v \end{aligned}$$

From the preceding relations, a state equation is

$$\mathbf{z}_{t+1} = F\mathbf{z}_t + K\mathbf{x}_t^* + G\mathbf{e}_{t+1}$$

and an observation equation is

$$\mathbf{y}_t = H\mathbf{z}_t$$

where

$$\mathbf{z}_t = \begin{bmatrix} \mathbf{y}_t \\ \mathbf{y}_{t+1|t} \\ \vdots \\ \mathbf{y}_{t+v-1|t} \\ \mathbf{x}_t \\ \mathbf{x}_{t+1|t} \\ \vdots \\ \mathbf{x}_{t+v-1|t} \end{bmatrix}, \quad \mathbf{x}_t^* = \begin{bmatrix} \mathbf{x}_{t+v-u} \\ \mathbf{x}_{t+v-u+1} \\ \vdots \\ \mathbf{x}_{t-1} \end{bmatrix}, \quad \mathbf{e}_{t+1} = \begin{bmatrix} \mathbf{a}_{t+1} \\ \boldsymbol{\epsilon}_{t+1} \end{bmatrix}$$

$$F = \begin{bmatrix} 0 & I_k & 0 & \cdots & 0 & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & I_k & \cdots & 0 & 0 & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ \Phi_v & \Phi_{v-1} & \Phi_{v-2} & \cdots & \Phi_1 & \Pi_v & \Pi_{v-1} & \Pi_{v-2} & \cdots & \Pi_1 \\ 0 & 0 & 0 & \cdots & 0 & 0 & I_r & 0 & \cdots & 0 \\ 0 & 0 & 0 & \cdots & 0 & 0 & 0 & I_r & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & A_v & A_{v-1} & A_{v-2} & \cdots & A_1 \end{bmatrix}$$

$$K = \begin{bmatrix} 0 & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ \Pi_u & \Pi_{u-1} & \cdots & \Pi_{v+1} \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{bmatrix}, \quad G = \begin{bmatrix} V_0 & I_k \\ V_1 & \Psi_1 \\ \vdots & \vdots \\ V_{v-1} & \Psi_{v-1} \\ I_r & 0_{r \times k} \\ \Psi_1^x & 0_{r \times k} \\ \vdots & \vdots \\ \Psi_{v-1}^x & 0_{r \times k} \end{bmatrix}$$

and

$$H = [I_k, 0_{k \times k}, \dots, 0_{k \times k}, 0_{k \times r}, \dots, 0_{k \times r}]$$

Note that the matrix K and the input vector \mathbf{x}_t^* are defined only when $u > v$.

Dynamic Simultaneous Equations Modeling

In the econometrics literature, the VARMAX(p, q, s) model is sometimes written in a form that is slightly different than the one shown in the previous section. This alternative form is referred to as a *dynamic simultaneous equations* model or a *dynamic structural equations* model.

Since $E(\epsilon_t \epsilon_t') = \Sigma$ is assumed to be positive-definite, there exists a lower triangular matrix A_0 with ones on the diagonals such that $A_0 \Sigma A_0' = \Sigma^d$, where Σ^d is a diagonal matrix with positive diagonal elements.

$$A_0 \mathbf{y}_t = \sum_{i=1}^p A_i \mathbf{y}_{t-i} + \sum_{i=0}^s C_i^* \mathbf{x}_{t-i} + C_0 \epsilon_t - \sum_{i=1}^q C_i \epsilon_{t-i}$$

where $A_i = A_0 \Phi_i$, $C_i^* = A_0 \Theta_i^*$, $C_0 = A_0$, and $C_i = A_0 \Theta_i$.

As an alternative form,

$$A_0 \mathbf{y}_t = \sum_{i=1}^p A_i \mathbf{y}_{t-i} + \sum_{i=0}^s C_i^* \mathbf{x}_{t-i} + \mathbf{a}_t - \sum_{i=1}^q C_i \mathbf{a}_{t-i}$$

where $A_i = A_0 \Phi_i$, $C_i^* = A_0 \Theta_i^*$, $C_i = A_0 \Theta_i A_0^{-1}$, and $\mathbf{a}_t = C_0 \epsilon_t$ has a diagonal covariance matrix Σ^d . The PRINT=(DYNAMIC) option returns the parameter estimates that result from estimating the model in this form.

A dynamic simultaneous equations model involves a leading (lower triangular) coefficient matrix for \mathbf{y}_t at lag 0 or a leading coefficient matrix for ϵ_t at lag 0. Such a representation of the VARMAX(p, q, s) model can be more useful in certain circumstances than the standard representation. From the linear combination of the dependent variables obtained by $A_0 \mathbf{y}_t$, you can easily see the relationship between the dependent variables in the current time.

The following statements provide the dynamic simultaneous equations of the VAR(1) model.

```
proc iml;
  sig = {1.0 0.5, 0.5 1.25};
  phi = {1.2 -0.5, 0.6 0.3};
  /* simulate the vector time series */
  call varmasim(y, phi) sigma = sig n = 100 seed = 34657;
  cn = {'y1' 'y2'};
  create simull from y[colname=cn];
  append from y;
quit;

data simull;
  set simull;
  date = intnx('year', '01jan1900'd, _n_-1);
  format date year4.;
run;

proc varmax data=simull;
  model y1 y2 / p=1 noint print=(dynamic);
run;
```

This is the same data set and model used in the section “Getting Started: VARMAX Procedure” on page 2050. You can compare the results of the VARMA model form and the dynamic simultaneous equations model form.

Figure 32.25 Dynamic Simultaneous Equations (DYNAMIC Option)

y1	AR1_1_1	1.15977	0.05508	21.06	0.0001	y1(t-1)
	AR1_1_2	-0.51058	0.07140	-7.15	0.0001	y2(t-1)
y2	AR0_2_1	0.30845				y1(t)
	AR1_2_1	0.18861	0.05779	3.26	0.0015	y1(t-1)
	AR1_2_2	0.54247	0.07491	7.24	0.0001	y2(t-1)

In Figure 32.4 in the section “Getting Started: VARMAX Procedure” on page 2050, the covariance of ϵ_t estimated from the VARMAX model form is

$$\Sigma_{\epsilon} = \begin{pmatrix} 1.28875 & 0.39751 \\ 0.39751 & 1.41839 \end{pmatrix}$$

Figure 32.25 shows the results from estimating the model as a dynamic simultaneous equations model. By the decomposition of Σ_{ϵ} , you get a diagonal matrix (Σ_a) and a lower triangular matrix (A_0) such as $\Sigma_a = A_0 \Sigma_{\epsilon} A_0'$ where

$$\Sigma_a = \begin{pmatrix} 1.28875 & 0 \\ 0 & 1.29578 \end{pmatrix} \text{ and } A_0 = \begin{pmatrix} 1 & 0 \\ -0.30845 & 1 \end{pmatrix}$$

The lower triangular matrix (A_0) is shown in the left side of the simultaneous equations model. The parameter estimates in equations system are shown in the right side of the two-equations system.

The simultaneous equations model is written as

$$\begin{pmatrix} 1 & 0 \\ -0.30845 & 1 \end{pmatrix} \mathbf{y}_t = \begin{pmatrix} 1.15977 & -0.51058 \\ 0.18861 & 0.54247 \end{pmatrix} \mathbf{y}_{t-1} + \mathbf{a}_t$$

The resulting two-equation system can be written as

$$\begin{aligned} y_{1t} &= 1.15977y_{1,t-1} - 0.51058y_{2,t-1} + a_{1t} \\ y_{2t} &= 0.30845y_{1t} + 0.18861y_{1,t-1} + 0.54247y_{2,t-1} + a_{2t} \end{aligned}$$

Impulse Response Function

Simple Impulse Response Function (IMPULSE=SIMPLE Option)

The VARMAX(p, q, s) model has a convergent representation

$$\mathbf{y}_t = \Psi^*(B)\mathbf{x}_t + \Psi(B)\boldsymbol{\epsilon}_t$$

where $\Psi^*(B) = \Phi(B)^{-1}\Theta^*(B) = \sum_{j=0}^{\infty} \Psi_j^* B^j$ and $\Psi(B) = \Phi(B)^{-1}\Theta(B) = \sum_{j=0}^{\infty} \Psi_j B^j$.

The elements of the matrices Ψ_j from the operator $\Psi(B)$, called the impulse response, can be interpreted as the impact that a shock in one variable has on another variable. Let $\psi_{j,in}$ be the in^{th} element of Ψ_j at lag j , where i is the index for the impulse variable, and n is the index for the response variable (impulse \rightarrow response). For instance, $\psi_{j,11}$ is an impulse response to $y_{1t} \rightarrow y_{1t}$, and $\psi_{j,12}$ is an impulse response to $y_{1t} \rightarrow y_{2t}$.

Accumulated Impulse Response Function (IMPULSE=ACCUM Option)

The accumulated impulse response function is the cumulative sum of the impulse response function, $\Psi_l^a = \sum_{j=0}^l \Psi_j$.

Orthogonalized Impulse Response Function (IMPULSE=ORTH Option)

The MA representation of a VARMA(p, q) model with a standardized white noise innovation process offers another way to interpret a VARMA(p, q) model. Since Σ is positive-definite, there is a lower triangular matrix P such that $\Sigma = PP'$. The alternate MA representation of a VARMA(p, q) model is written as

$$\mathbf{y}_t = \Psi^o(B)\mathbf{u}_t$$

where $\Psi^o(B) = \sum_{j=0}^{\infty} \Psi_j^o B^j$, $\Psi_j^o = \Psi_j P$, and $\mathbf{u}_t = P^{-1}\boldsymbol{\epsilon}_t$.

The elements of the matrices Ψ_j^o , called the *orthogonal impulse response*, can be interpreted as the effects of the components of the standardized shock process \mathbf{u}_t on the process \mathbf{y}_t at lag j .

Impulse Response of Transfer Function (IMPULSX=SIMPLE Option)

The coefficient matrix Ψ_j^* from the transfer function operator $\Psi^*(B)$ can be interpreted as the effects that changes in the exogenous variables \mathbf{x}_t have on the output variable \mathbf{y}_t at lag j ; it is called an impulse response matrix in the transfer function.

Impulse Response of Transfer Function (IMPULSX=ACCUM Option)

The accumulated impulse response in the transfer function is the cumulative sum of the impulse response in the transfer function, $\Psi_t^{*a} = \sum_{j=0}^t \Psi_j^*$.

The asymptotic distributions of the impulse functions can be seen in the section “VAR and VARX Modeling” on page 2133.

The following statements provide the impulse response and the accumulated impulse response in the transfer function for a VARX(1,0) model.

```
proc varmax data=grunfeld plot=impulse;
  model y1-y3 = x1 x2 / p=1 lagmax=5
          printform=univariate
          print=(impulsx=(all) estimates);
run;
```

In Figure 32.26, the variables x_1 and x_2 are impulses and the variables y_1 , y_2 , and y_3 are responses. You can read the table matching the pairs of *impulse* \rightarrow *response* such as $x_1 \rightarrow y_1$, $x_1 \rightarrow y_2$, $x_1 \rightarrow y_3$, $x_2 \rightarrow y_1$, $x_2 \rightarrow y_2$, and $x_2 \rightarrow y_3$. In the pair of $x_1 \rightarrow y_1$, you can see the long-run responses of y_1 to an impulse in x_1 (the values are 1.69281, 0.35399, 0.09090, and so on for lag 0, lag 1, lag 2, and so on, respectively).

Figure 32.29 shows the accumulated responses of y_1 , y_2 , and y_3 to a forecast error impulse in x_1 .

Figure 32.29 Plot of Accumulated Impulse Response in Transfer Function

The following statements provide the impulse response function, the accumulated impulse response function, and the orthogonalized impulse response function with their standard errors for a VAR(1) model. Parts of the VARMAX procedure output are shown in Figure 32.30, Figure 32.32, and Figure 32.34.

```
proc varmax data=simul1 plot=impulse;
  model y1 y2 / p=1 noint lagmax=5
          print=(impulse=(all))
          printform=univariate;
run;
```

Figure 32.30 is the output in a univariate format associated with the PRINT=(IMPULSE=) option for the impulse response function. The keyword STD stands for the standard errors of the elements. The matrix in terms of the lag 0 does not print since it is the identity. In Figure 32.30, the variables y_1 and y_2 of the first row are impulses, and the variables y_1 and y_2 of the first column are responses. You can read the table matching the *impulse* \rightarrow *response* pairs, such as $y_1 \rightarrow y_1$, $y_1 \rightarrow y_2$, $y_2 \rightarrow y_1$, and $y_2 \rightarrow y_2$. For example, in the pair of $y_1 \rightarrow y_1$ at lag 3, the response is 0.8055. This represents the impact on y_1 of one-unit change in y_1 after 3 periods. As the lag gets higher, you can see the long-run responses of y_1 to an impulse in itself.

In Figure 32.4, there is a positive correlation between ε_{1t} and ε_{2t} . Therefore, shock in $y1$ can be accompanied by a shock in $y2$ in the same period. For example, in the pair of $y1_innovation \rightarrow y2$, you can see the long-run responses of $y2$ to an impulse in $y1_innovation$.

Figure 32.35 shows the orthogonalized responses of y_1 and y_2 to a forecast error impulse in y_1 with two standard errors.

Figure 32.35 Plot of Orthogonalized Impulse Response

Forecasting

The optimal (minimum MSE) l -step-ahead forecast of \mathbf{y}_{t+l} is

$$\mathbf{y}_{t+l|t} = \sum_{j=1}^p \Phi_j \mathbf{y}_{t+l-j|t} + \sum_{j=0}^s \Theta_j^* \mathbf{x}_{t+l-j|t} - \sum_{j=l}^q \Theta_j \boldsymbol{\epsilon}_{t+l-j}, \quad l \leq q$$

$$\mathbf{y}_{t+l|t} = \sum_{j=1}^p \Phi_j \mathbf{y}_{t+l-j|t} + \sum_{j=0}^s \Theta_j^* \mathbf{x}_{t+l-j|t}, \quad l > q$$

with $\mathbf{y}_{t+l-j|t} = \mathbf{y}_{t+l-j}$ and $\mathbf{x}_{t+l-j|t} = \mathbf{x}_{t+l-j}$ for $l \leq j$. For the forecasts $\mathbf{x}_{t+l-j|t}$, see the section “State-Space Representation” on page 2105.

Covariance Matrices of Prediction Errors without Exogenous (Independent) Variables

Under the stationarity assumption, the optimal (minimum MSE) l -step-ahead forecast of \mathbf{y}_{t+l} has an infinite moving-average form, $\mathbf{y}_{t+l|t} = \sum_{j=l}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$. The prediction error of the optimal l -step-ahead forecast is $\mathbf{e}_{t+l|t} = \mathbf{y}_{t+l} - \mathbf{y}_{t+l|t} = \sum_{j=0}^{l-1} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$, with zero mean and covariance matrix,

$$\Sigma(l) = \text{Cov}(\mathbf{e}_{t+l|t}) = \sum_{j=0}^{l-1} \Psi_j \Sigma \Psi_j' = \sum_{j=0}^{l-1} \Psi_j^o \Psi_j^{o'}$$

where $\Psi_j^o = \Psi_j P$ with a lower triangular matrix P such that $\Sigma = PP'$. Under the assumption of normality of the $\boldsymbol{\epsilon}_t$, the l -step-ahead prediction error $\mathbf{e}_{t+l|t}$ is also normally distributed as multivariate $N(0, \Sigma(l))$. Hence, it follows that the diagonal elements $\sigma_{ii}^2(l)$ of $\Sigma(l)$ can be used, together with the point forecasts $y_{i,t+l|t}$, to construct l -step-ahead prediction intervals of the future values of the component series, $y_{i,t+l}$.

The following statements use the COVPE option to compute the covariance matrices of the prediction errors for a VAR(1) model. The parts of the VARMAX procedure output are shown in Figure 32.36 and Figure 32.37.

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=5
    printform=both
    print=(decompose(5) impulse=(all) covpe(5));
run;
```

Figure 32.36 is the output in a matrix format associated with the COVPE option for the prediction error covariance matrices.

Figure 32.36 Covariances of Prediction Errors (COVPE Option)

The VARMAX Procedure

	5	3.85346	5.07010

Covariance Matrices of Prediction Errors in the Presence of Exogenous (Independent) Variables

Exogenous variables can be both stochastic and nonstochastic (deterministic) variables. Considering the forecasts in the VARMAX(p, q, s) model, there are two cases.

When exogenous (independent) variables are stochastic (future values not specified):

As defined in the section “State-Space Representation” on page 2105, $\mathbf{y}_{t+l|t}$ has the representation

$$\mathbf{y}_{t+l|t} = \sum_{j=l}^{\infty} V_j \mathbf{a}_{t+l-j} + \sum_{j=l}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$$

and hence

$$\mathbf{e}_{t+l|t} = \sum_{j=0}^{l-1} V_j \mathbf{a}_{t+l-j} + \sum_{j=0}^{l-1} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$$

Therefore, the covariance matrix of the l -step-ahead prediction error is given as

$$\Sigma(l) = \text{Cov}(\mathbf{e}_{t+l|t}) = \sum_{j=0}^{l-1} V_j \Sigma_a V_j' + \sum_{j=0}^{l-1} \Psi_j \Sigma_{\epsilon} \Psi_j'$$

where Σ_a is the covariance of the white noise series \mathbf{a}_t , and \mathbf{a}_t is the white noise series for the VARMA(p, q) model of exogenous (independent) variables, which is assumed not to be correlated with $\boldsymbol{\epsilon}_t$ or its lags.

When future exogenous (independent) variables are specified:

The optimal forecast $\mathbf{y}_{t+l|t}$ of \mathbf{y}_t conditioned on the past information and also on known future values $\mathbf{x}_{t+1}, \dots, \mathbf{x}_{t+l}$ can be represented as

$$\mathbf{y}_{t+l|t} = \sum_{j=0}^{\infty} \Psi_j^* \mathbf{x}_{t+l-j} + \sum_{j=l}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$$

and the forecast error is

$$\mathbf{e}_{t+l|t} = \sum_{j=0}^{l-1} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$$

Thus, the covariance matrix of the l -step-ahead prediction error is given as

$$\Sigma(l) = \text{Cov}(\mathbf{e}_{t+l|t}) = \sum_{j=0}^{l-1} \Psi_j \Sigma_{\epsilon} \Psi_j'$$

Decomposition of Prediction Error Covariances

In the relation $\Sigma(l) = \sum_{j=0}^{l-1} \Psi_j^o \Psi_j^{o'}$, the diagonal elements can be interpreted as providing a decomposition of the l -step-ahead prediction error covariance $\sigma_{ii}^2(l)$ for each component series y_{it} into contributions from the components of the standardized innovations $\boldsymbol{\epsilon}_t$.

If you denote the (i, n) th element of Ψ_j^o by $\psi_{j,in}$, the MSE of $y_{i,t+h|t}$ is

$$\text{MSE}(y_{i,t+h|t}) = \text{E}(y_{i,t+h} - y_{i,t+h|t})^2 = \sum_{j=0}^{l-1} \sum_{n=1}^k \psi_{j,in}^2$$

Note that $\sum_{j=0}^{l-1} \psi_{j,in}^2$ is interpreted as the contribution of innovations in variable n to the prediction error covariance of the l -step-ahead forecast of variable i .

The proportion, $\omega_{l,in}$, of the l -step-ahead forecast error covariance of variable i accounting for the innovations in variable n is

$$\omega_{l,in} = \sum_{j=0}^{l-1} \psi_{j,in}^2 / \text{MSE}(y_{i,t+h|t})$$

The following statements use the DECOMPOSE option to compute the decomposition of prediction error covariances and their proportions for a VAR(1) model:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint print=(decompose(15))
          printform=univariate;
run;
```

The proportions of decomposition of prediction error covariances of two variables are given in Figure 32.38. The output explains that about 91.356% of the one-step-ahead prediction error covariances of the variable y_{2t} is accounted for by its own innovations and about 8.644% is accounted for by y_{1t} innovations.

Figure 32.38 Decomposition of Prediction Error Covariances (DECOMPOSE Option)

Proportions of Prediction Error Covariances by Variable

	5	0.53549	0.46451

Forecasting of the Centered Series

If the CENTER option is specified, the sample mean vector is added to the forecast.

Forecasting of the Differenced Series

If dependent (endogenous) variables are differenced, the final forecasts and their prediction error covariances are produced by integrating those of the differenced series. However, if the PRIOR option is specified, the forecasts and their prediction error variances of the differenced series are produced.

Let \mathbf{z}_t be the original series with some appended zero values that correspond to the unobserved past observations. Let $\Delta(B)$ be the $k \times k$ matrix polynomial in the backshift operator that corresponds to the differencing specified by the MODEL statement. The off-diagonal elements of Δ_i are zero, and the diagonal elements can be different. Then $\mathbf{y}_t = \Delta(B)\mathbf{z}_t$.

This gives the relationship

$$\mathbf{z}_t = \Delta^{-1}(B)\mathbf{y}_t = \sum_{j=0}^{\infty} \Lambda_j \mathbf{y}_{t-j}$$

where $\Delta^{-1}(B) = \sum_{j=0}^{\infty} \Lambda_j B^j$ and $\Lambda_0 = I_k$.

The l -step-ahead prediction of \mathbf{z}_{t+l} is

$$\mathbf{z}_{t+l|t} = \sum_{j=0}^{l-1} \Lambda_j \mathbf{y}_{t+l-j|t} + \sum_{j=l}^{\infty} \Lambda_j \mathbf{y}_{t+l-j}$$

The l -step-ahead prediction error of \mathbf{z}_{t+l} is

$$\sum_{j=0}^{l-1} \Lambda_j (\mathbf{y}_{t+l-j} - \mathbf{y}_{t+l-j|t}) = \sum_{j=0}^{l-1} \left(\sum_{u=0}^j \Lambda_u \Psi_{j-u} \right) \boldsymbol{\epsilon}_{t+l-j}$$

Letting $\Sigma_{\mathbf{z}}(0) = 0$, the covariance matrix of the l -step-ahead prediction error of \mathbf{z}_{t+l} , $\Sigma_{\mathbf{z}}(l)$, is

$$\begin{aligned} \Sigma_{\mathbf{z}}(l) &= \sum_{j=0}^{l-1} \left(\sum_{u=0}^j \Lambda_u \Psi_{j-u} \right) \Sigma_{\boldsymbol{\epsilon}} \left(\sum_{u=0}^j \Lambda_u \Psi_{j-u} \right)' \\ &= \Sigma_{\mathbf{z}}(l-1) + \left(\sum_{j=0}^{l-1} \Lambda_j \Psi_{l-1-j} \right) \Sigma_{\boldsymbol{\epsilon}} \left(\sum_{j=0}^{l-1} \Lambda_j \Psi_{l-1-j} \right)' \end{aligned}$$

If there are stochastic exogenous (independent) variables, the covariance matrix of the l -step-ahead prediction error of \mathbf{z}_{t+l} , $\Sigma_{\mathbf{z}}(l)$, is

$$\begin{aligned} \Sigma_{\mathbf{z}}(l) &= \Sigma_{\mathbf{z}}(l-1) + \left(\sum_{j=0}^{l-1} \Lambda_j \Psi_{l-1-j} \right) \Sigma_{\boldsymbol{\epsilon}} \left(\sum_{j=0}^{l-1} \Lambda_j \Psi_{l-1-j} \right)' \\ &\quad + \left(\sum_{j=0}^{l-1} \Lambda_j V_{l-1-j} \right) \Sigma_a \left(\sum_{j=0}^{l-1} \Lambda_j V_{l-1-j} \right)' \end{aligned}$$

Tentative Order Selection

Sample Cross-Covariance and Cross-Correlation Matrices

Given a stationary multivariate time series \mathbf{y}_t , cross-covariance matrices are

$$\Gamma(l) = E[(\mathbf{y}_t - \boldsymbol{\mu})(\mathbf{y}_{t+l} - \boldsymbol{\mu})']$$

where $\boldsymbol{\mu} = E(\mathbf{y}_t)$, and cross-correlation matrices are

$$\rho(l) = D^{-1} \Gamma(l) D^{-1}$$

where D is a diagonal matrix with the standard deviations of the components of \mathbf{y}_t on the diagonal.

The sample cross-covariance matrix at lag l , denoted as $C(l)$, is computed as

$$\hat{\Gamma}(l) = C(l) = \frac{1}{T} \sum_{t=1}^{T-l} \tilde{\mathbf{y}}_t \tilde{\mathbf{y}}_{t+l}'$$

where \tilde{y}_t is the centered data and T is the number of nonmissing observations. Thus, $\hat{\Gamma}(l)$ has (i, j) th element $\hat{\gamma}_{ij}(l) = c_{ij}(l)$. The sample cross-correlation matrix at lag l is computed as

$$\hat{\rho}_{ij}(l) = c_{ij}(l)/[c_{ii}(0)c_{jj}(0)]^{1/2}, \quad i, j = 1, \dots, k$$

The following statements use the CORRY option to compute the sample cross-correlation matrices and their summary indicator plots in terms of +, −, and ·, where + indicates significant positive cross-correlations, − indicates significant negative cross-correlations, and · indicates insignificant cross-correlations.

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=3 print=(corry)
             printform=univariate;
run;
```

Figure 32.39 shows the sample cross-correlation matrices of y_{1t} and y_{2t} . As shown, the sample autocorrelation functions for each variable decay quickly, but are significant with respect to two standard errors.

Figure 32.39 Cross-Correlations (CORRY Option)

Partial Autoregressive Matrices

For each $m = 1, 2, \dots, p$ you can define a sequence of matrices Φ_{mm} , which is called the partial autoregression matrices of lag m , as the solution for Φ_{mm} to the Yule-Walker equations of order m ,

$$\Gamma(l) = \sum_{i=1}^m \Gamma(l-i) \Phi'_{im}, \quad l = 1, 2, \dots, m$$

The sequence of the partial autoregression matrices Φ_{mm} of order m has the characteristic property that if the process follows the $AR(p)$, then $\Phi_{pp} = \Phi_p$ and $\Phi_{mm} = 0$ for $m > p$. Hence, the matrices Φ_{mm} have the cutoff property for a $VAR(p)$ model, and so they can be useful in the identification of the order of a pure VAR model.

The following statements use the PARCOEF option to compute the partial autoregression matrices:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=3
    printform=univariate
    print=(corry parcoef pcorr
           pcancorr roots);
run;
```

Figure 32.40 shows that the model can be obtained by an AR order $m = 1$ since partial autoregression matrices are insignificant after lag 1 with respect to two standard errors. The matrix for lag 1 is the same as the Yule-Walker autoregressive matrix.

Figure 32.40 Partial Autoregression Matrices (PARCOEF Option)

Partial Correlation Matrices

Define the forward autoregression

$$\mathbf{y}_t = \sum_{i=1}^{m-1} \Phi_{i,m-1} \mathbf{y}_{t-i} + \mathbf{u}_{m,t}$$

and the backward autoregression

$$\mathbf{y}_{t-m} = \sum_{i=1}^{m-1} \Phi_{i,m-1}^* \mathbf{y}_{t-m+i} + \mathbf{u}_{m,t-m}^*$$

The matrices $P(m)$ defined by Ansley and Newbold (1979) are given by

$$P(m) = \Sigma_{m-1}^{*1/2} \Phi_{mm}' \Sigma_{m-1}^{-1/2}$$

where

$$\Sigma_{m-1} = \text{Cov}(\mathbf{u}_{m,t}) = \Gamma(0) - \sum_{i=1}^{m-1} \Gamma(-i) \Phi_{i,m-1}'$$

and

$$\Sigma_{m-1}^* = \text{Cov}(\mathbf{u}_{m,t-m}^*) = \Gamma(0) - \sum_{i=1}^{m-1} \Gamma(m-i) \Phi_{m-i,m-1}^{*'}$$

$P(m)$ are the partial cross-correlation matrices at lag m between the elements of \mathbf{y}_t and \mathbf{y}_{t-m} , given $\mathbf{y}_{t-1}, \dots, \mathbf{y}_{t-m+1}$. The matrices $P(m)$ have the cutoff property for a VAR(p) model, and so they can be useful in the identification of the order of a pure VAR structure.

The following statements use the PCORR option to compute the partial cross-correlation matrices:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=3
          print=(pcorr)
          printform=univariate;
run;
```

The partial cross-correlation matrices in [Figure 32.41](#) are insignificant after lag 1 with respect to two standard errors. This indicates that an AR order of $m = 1$ can be an appropriate choice.

Figure 32.41 Partial Correlations (PCORR Option)

Partial Canonical Correlation Matrices

The partial canonical correlations at lag m between the vectors \mathbf{y}_t and \mathbf{y}_{t-m} , given $\mathbf{y}_{t-1}, \dots, \mathbf{y}_{t-m+1}$, are $1 \geq \rho_1(m) \geq \rho_2(m) \geq \dots \geq \rho_k(m)$. The partial canonical correlations are the canonical correlations between the residual series $\mathbf{u}_{m,t}$ and $\mathbf{u}_{m,t-m}^*$, where $\mathbf{u}_{m,t}$ and $\mathbf{u}_{m,t-m}^*$ are defined in the previous section. Thus, the squared partial canonical correlations $\rho_i^2(m)$ are the eigenvalues of the matrix

$$\{\text{Cov}(\mathbf{u}_{m,t})\}^{-1} \text{E}(\mathbf{u}_{m,t} \mathbf{u}_{m,t-m}^{*\prime}) \{\text{Cov}(\mathbf{u}_{m,t-m}^*)\}^{-1} \text{E}(\mathbf{u}_{m,t-m}^* \mathbf{u}_{m,t}^{\prime}) = \Phi_{mm}^{*\prime} \Phi_{mm}^{\prime}$$

It follows that the test statistic to test for $\Phi_m = 0$ in the VAR model of order $m > p$ is approximately

$$(T - m) \text{tr} \{\Phi_{mm}^{*\prime} \Phi_{mm}^{\prime}\} \approx (T - m) \sum_{i=1}^k \rho_i^2(m)$$

and has an asymptotic chi-square distribution with k^2 degrees of freedom for $m > p$.

The following statements use the PCANCORR option to compute the partial canonical correlations:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=3 print=(pcancorr);
run;
```

Figure 32.42 shows that the partial canonical correlations $\rho_i(m)$ between \mathbf{y}_t and \mathbf{y}_{t-m} are {0.918, 0.773}, {0.092, 0.018}, and {0.109, 0.011} for lags $m = 1$ to 3. After lag $m = 1$, the partial canonical correlations are insignificant with respect to the 0.05 significance level, indicating that an AR order of $m = 1$ can be an appropriate choice.

Figure 32.42 Partial Canonical Correlations (PCANCORR Option)

The VARMAX Procedure					
Partial Canonical Correlations					
Lag	Correlation1	Correlation2	DF	Chi-Square	Pr > ChiSq
1	0.91783	0.77335	4	142.61	<.0001
2	0.09171	0.01816	4	0.86	0.9307
3	0.10861	0.01078	4	1.16	0.8854

The Minimum Information Criterion (MINIC) Method

The minimum information criterion (MINIC) method can tentatively identify the orders of a VARMA(p, q) process. Note that Spliid (1983), Koreisha and Pukkila (1989), and Quinn (1980) proposed this method. The first step of this method is to obtain estimates of the innovations series, ϵ_t , from the VAR(p_ϵ), where p_ϵ is chosen sufficiently large. The choice of the autoregressive order, p_ϵ , is determined by use of a selection criterion. From the selected VAR(p_ϵ) model, you obtain estimates of residual series

$$\tilde{\epsilon}_t = \mathbf{y}_t - \sum_{i=1}^{p_\epsilon} \hat{\Phi}_i^{p_\epsilon} \mathbf{y}_{t-i} - \hat{\delta}^{p_\epsilon}, \quad t = p_\epsilon + 1, \dots, T$$

In the second step, you select the order (p, q) of the VARMA model for p in ($p_{min} : p_{max}$) and q in ($q_{min} : q_{max}$)

$$\mathbf{y}_t = \delta + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} - \sum_{i=1}^q \Theta_i \tilde{\epsilon}_{t-i} + \epsilon_t$$

which minimizes a selection criterion like SBC or HQ.

The following statements use the MINIC= option to compute a table that contains the information criterion associated with various AR and MA orders:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint minic=(p=3 q=3);
run;
```

Figure 32.43 shows the output associated with the MINIC= option. The criterion takes the smallest value at AR order 1.

Figure 32.43 MINIC= Option

The VARMAX Procedure				
Minimum Information Criterion Based on AICC				
Lag	MA 0	MA 1	MA 2	MA 3
AR 0	3.3574947	3.0331352	2.7080996	2.3049869
AR 1	0.5544431	0.6146887	0.6771732	0.7517968
AR 2	0.6369334	0.6729736	0.7610413	0.8481559
AR 3	0.7235629	0.7551756	0.8053765	0.8654079

VAR and VARX Modeling

The p th-order VAR process is written as

$$\mathbf{y}_t - \boldsymbol{\mu} = \sum_{i=1}^p \Phi_i (\mathbf{y}_{t-i} - \boldsymbol{\mu}) + \boldsymbol{\epsilon}_t \quad \text{or} \quad \Phi(B)(\mathbf{y}_t - \boldsymbol{\mu}) = \boldsymbol{\epsilon}_t$$

with $\Phi(B) = I_k - \sum_{i=1}^p \Phi_i B^i$.

Equivalently, it can be written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t \quad \text{or} \quad \Phi(B)\mathbf{y}_t = \boldsymbol{\delta} + \boldsymbol{\epsilon}_t$$

with $\boldsymbol{\delta} = (I_k - \sum_{i=1}^p \Phi_i)\boldsymbol{\mu}$.

Stationarity

For stationarity, the VAR process must be expressible in the convergent causal infinite MA form as

$$\mathbf{y}_t = \boldsymbol{\mu} + \sum_{j=0}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t-j}$$

where $\Psi(B) = \Phi(B)^{-1} = \sum_{j=0}^{\infty} \Psi_j B^j$ with $\sum_{j=0}^{\infty} \|\Psi_j\| < \infty$, where $\|A\|$ denotes a norm for the matrix A such as $\|A\|^2 = \text{tr}\{A'A\}$. The matrix Ψ_j can be recursively obtained from the relation $\Phi(B)\Psi(B) = I$; it is

$$\Psi_j = \Phi_1 \Psi_{j-1} + \Phi_2 \Psi_{j-2} + \cdots + \Phi_p \Psi_{j-p}$$

where $\Psi_0 = I_k$ and $\Psi_j = 0$ for $j < 0$.

The stationarity condition is satisfied if all roots of $|\Phi(z)| = 0$ are outside of the unit circle. The stationarity condition is equivalent to the condition in the corresponding VAR(1) representation, $\mathbf{Y}_t = \Phi \mathbf{Y}_{t-1} + \boldsymbol{\varepsilon}_t$, that all eigenvalues of the $kp \times kp$ companion matrix Φ be less than one in absolute value, where $\mathbf{Y}_t = (\mathbf{y}'_t, \dots, \mathbf{y}'_{t-p+1})'$, $\boldsymbol{\varepsilon}_t = (\boldsymbol{\varepsilon}'_t, 0', \dots, 0)'$, and

$$\Phi = \begin{bmatrix} \Phi_1 & \Phi_2 & \cdots & \Phi_{p-1} & \Phi_p \\ I_k & 0 & \cdots & 0 & 0 \\ 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & I_k & 0 \end{bmatrix}$$

If the stationarity condition is not satisfied, a nonstationary model (a differenced model or an error correction model) might be more appropriate.

The following statements estimate a VAR(1) model and use the ROOTS option to compute the characteristic polynomial roots:

```
proc varmax data=simul1;
  model y1 y2 / p=1 noint print=(roots);
run;
```

Figure 32.44 shows the output associated with the ROOTS option, which indicates that the series is stationary since the modulus of the eigenvalue is less than one.

Figure 32.44 Stationarity (ROOTS Option)

The VARMAX Procedure					
Roots of AR Characteristic Polynomial					
Index	Real	Imaginary	Modulus	Radian	Degree
1	0.77238	0.35899	0.8517	0.4351	24.9284
2	0.77238	-0.35899	0.8517	-0.4351	-24.9284

Parameter Estimation

Consider the stationary VAR(p) model

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \boldsymbol{\varepsilon}_t$$

where $\mathbf{y}_{-p+1}, \dots, \mathbf{y}_0$ are assumed to be available (for convenience of notation). This can be represented by the general form of the multivariate linear model,

$$Y = XB + E \quad \text{or} \quad \mathbf{y} = (X \otimes I_k)\boldsymbol{\beta} + \mathbf{e}$$

where

$$\begin{aligned}
 Y &= (\mathbf{y}_1, \dots, \mathbf{y}_T)' \\
 B &= (\boldsymbol{\delta}, \Phi_1, \dots, \Phi_p)' \\
 X &= (X_0, \dots, X_{T-1})' \\
 X_t &= (1, \mathbf{y}'_t, \dots, \mathbf{y}'_{t-p+1})' \\
 E &= (\boldsymbol{\epsilon}_1, \dots, \boldsymbol{\epsilon}_T)' \\
 \mathbf{y} &= \text{vec}(Y') \\
 \boldsymbol{\beta} &= \text{vec}(B') \\
 \mathbf{e} &= \text{vec}(E')
 \end{aligned}$$

with vec denoting the column stacking operator.

The conditional least squares estimator of $\boldsymbol{\beta}$ is

$$\hat{\boldsymbol{\beta}} = ((X'X)^{-1}X' \otimes I_k)\mathbf{y}$$

and the estimate of Σ is

$$\hat{\Sigma} = (T - (kp + 1))^{-1} \sum_{t=1}^T \hat{\boldsymbol{\epsilon}}_t \hat{\boldsymbol{\epsilon}}_t'$$

where $\hat{\boldsymbol{\epsilon}}_t$ is the residual vectors. Consistency and asymptotic normality of the LS estimator are that

$$\sqrt{T}(\hat{\boldsymbol{\beta}} - \boldsymbol{\beta}) \xrightarrow{d} N(0, \Gamma_p^{-1} \otimes \Sigma)$$

where $X'X/T$ converges in probability to Γ_p and \xrightarrow{d} denotes convergence in distribution.

The (conditional) maximum likelihood estimator in the VAR(p) model is equal to the (conditional) least squares estimator on the assumption of normality of the error vectors.

Asymptotic Distributions of Impulse Response Functions

As before, vec denotes the column stacking operator and vech is the corresponding operator that stacks the elements on and below the diagonal. For any $k \times k$ matrix A , the commutation matrix K_k is defined as $K_k \text{vec}(A) = \text{vec}(A')$; the duplication matrix D_k is defined as $D_k \text{vech}(A) = \text{vec}(A)$; the elimination matrix L_k is defined as $L_k \text{vec}(A) = \text{vech}(A)$.

The asymptotic distribution of the impulse response function (Lütkepohl 1993) is

$$\sqrt{T} \text{vec}(\hat{\Psi}_j - \Psi_j) \xrightarrow{d} N(0, G_j \Sigma_{\boldsymbol{\beta}} G_j') \quad j = 1, 2, \dots$$

where $\Sigma_{\boldsymbol{\beta}} = \Gamma_p^{-1} \otimes \Sigma$ and

$$G_j = \frac{\partial \text{vec}(\Psi_j)}{\partial \boldsymbol{\beta}'} = \sum_{i=0}^{j-1} \mathbf{J}(\boldsymbol{\Phi}')^{j-1-i} \otimes \Psi_i$$

where $\mathbf{J} = [I_k, 0, \dots, 0]$ is a $k \times kp$ matrix and $\boldsymbol{\Phi}$ is a $kp \times kp$ companion matrix.

The asymptotic distribution of the accumulated impulse response function is

$$\sqrt{T} \text{vec}(\hat{\Psi}_l^a - \Psi_l^a) \xrightarrow{d} N(0, F_l \Sigma_{\beta} F_l') \quad l = 1, 2, \dots$$

where $F_l = \sum_{j=1}^l G_j$.

The asymptotic distribution of the orthogonalized impulse response function is

$$\sqrt{T} \text{vec}(\hat{\Psi}_j^o - \Psi_j^o) \xrightarrow{d} N(0, C_j \Sigma_{\beta} C_j' + \bar{C}_j \Sigma_{\sigma} \bar{C}_j') \quad j = 0, 1, 2, \dots$$

where $C_0 = 0$, $C_j = (\Psi_0^{o'} \otimes I_k) G_j$, $\bar{C}_j = (I_k \otimes \Psi_j) H$,

$$H = \frac{\partial \text{vec}(\Psi_0^o)}{\partial \sigma'} = L_k' \{L_k (I_{k^2} + K_k) (\Psi_0^o \otimes I_k) L_k'\}^{-1}$$

and $\Sigma_{\sigma} = 2D_k^+ (\Sigma \otimes \Sigma) D_k^{+'}$ with $D_k^+ = (D_k' D_k)^{-1} D_k'$ and $\sigma = \text{vech}(\mathbb{E})$.

Granger Causality Test

Let \mathbf{y}_t be arranged and partitioned in subgroups \mathbf{y}_{1t} and \mathbf{y}_{2t} with dimensions k_1 and k_2 , respectively ($k = k_1 + k_2$); that is, $\mathbf{y}_t = (\mathbf{y}'_{1t}, \mathbf{y}'_{2t})'$ with the corresponding white noise process $\boldsymbol{\epsilon}_t = (\boldsymbol{\epsilon}'_{1t}, \boldsymbol{\epsilon}'_{2t})'$. Consider the VAR(p) model with partitioned coefficients $\Phi_{ij}(B)$ for $i, j = 1, 2$ as follows:

$$\begin{bmatrix} \Phi_{11}(B) & \Phi_{12}(B) \\ \Phi_{21}(B) & \Phi_{22}(B) \end{bmatrix} \begin{bmatrix} \mathbf{y}_{1t} \\ \mathbf{y}_{2t} \end{bmatrix} = \begin{bmatrix} \boldsymbol{\delta}_1 \\ \boldsymbol{\delta}_2 \end{bmatrix} + \begin{bmatrix} \boldsymbol{\epsilon}_{1t} \\ \boldsymbol{\epsilon}_{2t} \end{bmatrix}$$

The variables \mathbf{y}_{1t} are said to cause \mathbf{y}_{2t} , but \mathbf{y}_{2t} do not cause \mathbf{y}_{1t} if $\Phi_{12}(B) = 0$. The implication of this model structure is that future values of the process \mathbf{y}_{1t} are influenced only by its own past and not by the past of \mathbf{y}_{2t} , where future values of \mathbf{y}_{2t} are influenced by the past of both \mathbf{y}_{1t} and \mathbf{y}_{2t} . If the future \mathbf{y}_{1t} are not influenced by the past values of \mathbf{y}_{2t} , then it can be better to model \mathbf{y}_{1t} separately from \mathbf{y}_{2t} .

Consider testing $H_0: C\boldsymbol{\beta} = c$, where C is a $s \times (k^2 p + k)$ matrix of rank s and c is an s -dimensional vector where $s = k_1 k_2 p$. Assuming that

$$\sqrt{T}(\hat{\boldsymbol{\beta}} - \boldsymbol{\beta}) \xrightarrow{d} N(0, \Gamma_p^{-1} \otimes \Sigma)$$

you get the Wald statistic

$$T(C\hat{\boldsymbol{\beta}} - c)'[C(\hat{\Gamma}_p^{-1} \otimes \hat{\Sigma})C']^{-1}(C\hat{\boldsymbol{\beta}} - c) \xrightarrow{d} \chi^2(s)$$

For the Granger causality test, the matrix C consists of zeros or ones and c is the zero vector. See Lütkepohl(1993) for more details of the Granger causality test.

VARX Modeling

The vector autoregressive model with exogenous variables is called the VARX(p,s) model. The form of the VARX(p,s) model can be written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

The parameter estimates can be obtained by representing the general form of the multivariate linear model,

$$Y = XB + E \text{ or } \mathbf{y} = (X \otimes I_k)\boldsymbol{\beta} + \mathbf{e}$$

where

$$\begin{aligned} Y &= (\mathbf{y}_1, \dots, \mathbf{y}_T)' \\ B &= (\boldsymbol{\delta}, \Phi_1, \dots, \Phi_p, \Theta_0^*, \dots, \Theta_s^*)' \\ X &= (X_0, \dots, X_{T-1})' \\ X_t &= (1, \mathbf{y}'_t, \dots, \mathbf{y}'_{t-p+1}, \mathbf{x}'_{t+1}, \dots, \mathbf{x}'_{t-s+1})' \\ E &= (\boldsymbol{\epsilon}_1, \dots, \boldsymbol{\epsilon}_T)' \\ \mathbf{y} &= \text{vec}(Y') \\ \boldsymbol{\beta} &= \text{vec}(B') \\ \mathbf{e} &= \text{vec}(E') \end{aligned}$$

The conditional least squares estimator of $\boldsymbol{\beta}$ can be obtained by using the same method in a VAR(p) modeling. If the multivariate linear model has different independent variables that correspond to dependent variables, the SUR (seemingly unrelated regression) method is used to improve the regression estimates.

The following example fits the ordinary regression model:

```
proc varmax data=one;
  model y1-y3 = x1-x5;
run;
```

This is equivalent to the REG procedure in the SAS/STAT software:

```
proc reg data=one;
  model y1 = x1-x5;
  model y2 = x1-x5;
  model y3 = x1-x5;
run;
```

The following example fits the second-order lagged regression model:

```
proc varmax data=two;
  model y1 y2 = x / xlag=2;
run;
```

This is equivalent to the REG procedure in the SAS/STAT software:

```
data three;
  set two;
  xlag1 = lag1(x);
  xlag2 = lag2(x);
run;

proc reg data=three;
  model y1 = x xlag1 xlag2;
  model y2 = x xlag1 xlag2;
run;
```

The following example fits the ordinary regression model with different regressors:

```
proc varmax data=one;
  model y1 = x1-x3, y2 = x2 x3;
run;
```

This is equivalent to the following SYSLIN procedure statements:

```
proc syslin data=one vardef=df sur;
  endogenous y1 y2;
  model y1 = x1-x3;
  model y2 = x2 x3;
run;
```

From the output in [Figure 32.20](#) in the section “Getting Started: VARMAX Procedure” on page 2050, you can see that the parameters, XL0_1_2, XL0_2_1, XL0_3_1, and XL0_3_2 associated with the exogenous variables, are not significant. The following example fits the VARX(1,0) model with different regressors:

```
proc varmax data=grunfeld;
  model y1 = x1, y2 = x2, y3 / p=1 print=(estimates);
run;
```

Figure 32.45 Parameter Estimates for the VARX(1, 0) Model

The VARMAX Procedure				
XLAG				
Lag	Variable	x1	x2	
0	y1	1.83231	—	
	y2	—	2.42110	
	y3	—	—	

As you can see in Figure 32.45, the symbol ‘_’ in the elements of matrix corresponds to endogenous variables that do not take the denoted exogenous variables.

Bayesian VAR and VARX Modeling

Consider the VAR(p) model

$$\mathbf{y}_t = \boldsymbol{\delta} + \Phi_1 \mathbf{y}_{t-1} + \cdots + \Phi_p \mathbf{y}_{t-p} + \boldsymbol{\epsilon}_t$$

or

$$\mathbf{y} = (X \otimes I_k) \boldsymbol{\beta} + \mathbf{e}$$

When the parameter vector $\boldsymbol{\beta}$ has a prior multivariate normal distribution with known mean $\boldsymbol{\beta}^*$ and covariance matrix V_β , the prior density is written as

$$f(\boldsymbol{\beta}) = \left(\frac{1}{2\pi}\right)^{k^2 p/2} |V_\beta|^{-1/2} \exp\left[-\frac{1}{2}(\boldsymbol{\beta} - \boldsymbol{\beta}^*)' V_\beta^{-1} (\boldsymbol{\beta} - \boldsymbol{\beta}^*)\right]$$

The likelihood function for the Gaussian process becomes

$$\begin{aligned} \ell(\boldsymbol{\beta}|\mathbf{y}) &= \left(\frac{1}{2\pi}\right)^{kT/2} |I_T \otimes \Sigma|^{-1/2} \times \\ &\quad \exp\left[-\frac{1}{2}(\mathbf{y} - (X \otimes I_k)\boldsymbol{\beta})' (I_T \otimes \Sigma^{-1})(\mathbf{y} - (X \otimes I_k)\boldsymbol{\beta})\right] \end{aligned}$$

Therefore, the posterior density is derived as

$$f(\boldsymbol{\beta}|\mathbf{y}) \propto \exp\left[-\frac{1}{2}(\boldsymbol{\beta} - \bar{\boldsymbol{\beta}})' \bar{\Sigma}_\beta^{-1} (\boldsymbol{\beta} - \bar{\boldsymbol{\beta}})\right]$$

where the posterior mean is

$$\bar{\boldsymbol{\beta}} = [V_\beta^{-1} + (X'X \otimes \Sigma^{-1})]^{-1} [V_\beta^{-1} \boldsymbol{\beta}^* + (X' \otimes \Sigma^{-1})\mathbf{y}]$$

and the posterior covariance matrix is

$$\bar{\Sigma}_\beta = [V_\beta^{-1} + (X'X \otimes \Sigma^{-1})]^{-1}$$

In practice, the prior mean $\boldsymbol{\beta}^*$ and the prior variance V_β need to be specified. If all the parameters are considered to shrink toward zero, the null prior mean should be specified. According to Litterman (1986), the prior variance can be given by

$$v_{ij}(l) = \begin{cases} (\lambda/l)^2 & \text{if } i = j \\ (\lambda\theta\sigma_{ii}/l\sigma_{jj})^2 & \text{if } i \neq j \end{cases}$$

where $v_{ij}(l)$ is the prior variance of the (i, j) th element of Φ_l , λ is the prior standard deviation of the diagonal elements of Φ_l , θ is a constant in the interval $(0, 1)$, and σ_{ii}^2 is the i th diagonal element of Σ . The deterministic terms have diffused prior variance. In practice, you replace the σ_{ii}^2 by the diagonal element of the ML estimator of Σ in the nonconstrained model.

For example, for a bivariate BVAR(2) model,

$$\begin{aligned} y_{1t} &= 0 + \phi_{1,11}y_{1,t-1} + \phi_{1,12}y_{2,t-1} + \phi_{2,11}y_{1,t-2} + \phi_{2,12}y_{2,t-2} + \epsilon_{1t} \\ y_{2t} &= 0 + \phi_{1,21}y_{1,t-1} + \phi_{1,22}y_{2,t-1} + \phi_{2,21}y_{1,t-2} + \phi_{2,22}y_{2,t-2} + \epsilon_{2t} \end{aligned}$$

with the prior covariance matrix

$$V_{\beta} = \text{Diag} \left(\begin{array}{cccc} \infty, \lambda^2, (\lambda\theta\sigma_1/\sigma_2)^2, (\lambda/2)^2, (\lambda\theta\sigma_1/2\sigma_2)^2, \\ \infty, (\lambda\theta\sigma_2/\sigma_1)^2, \lambda^2, (\lambda\theta\sigma_2/2\sigma_1)^2, (\lambda/2)^2 \end{array} \right)$$

For the Bayesian estimation of integrated systems, the prior mean is set to the first lag of each variable equal to one in its own equation and all other coefficients at zero. For example, for a bivariate BVAR(2) model,

$$\begin{aligned} y_{1t} &= 0 + 1 y_{1,t-1} + 0 y_{2,t-1} + 0 y_{1,t-2} + 0 y_{2,t-2} + \epsilon_{1t} \\ y_{2t} &= 0 + 0 y_{1,t-1} + 1 y_{2,t-1} + 0 y_{1,t-2} + 0 y_{2,t-2} + \epsilon_{2t} \end{aligned}$$

Forecasting of BVAR Modeling

The mean squared error is used to measure forecast accuracy (Litterman 1986). The MSE of the forecast is

$$MSE = \frac{1}{T} \sum_{t=1}^T (A_t - F_t^s)^2$$

where A_t is the actual value at time t and F_t^s is the forecast made s periods earlier.

Bayesian VARX Modeling

The Bayesian vector autoregressive model with exogenous variables is called the BVARX(p, s) model. The form of the BVARX(p, s) model can be written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

The parameter estimates can be obtained by representing the general form of the multivariate linear model,

$$\mathbf{y} = (\mathbf{X} \otimes \mathbf{I}_k) \boldsymbol{\beta} + \mathbf{e}$$

The prior means for the AR coefficients are the same as those specified in $BVAR(p)$. The prior means for the exogenous coefficients are set to zero.

Some examples of the Bayesian VARX model are as follows:

```
model y1 y2 = x1 / p=1 xlag=1 prior;
```

```
model y1 y2 = x1 / p=(1 3) xlag=1 nocurrentx
                prior=(lambda=0.9 theta=0.1);
```

VARMA and VARMAX Modeling

A VARMA(p, q) process is written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t - \sum_{i=1}^q \Theta_i \boldsymbol{\epsilon}_{t-i}$$

or

$$\Phi(B)\mathbf{y}_t = \boldsymbol{\delta} + \Theta(B)\boldsymbol{\epsilon}_t$$

where $\Phi(B) = I_k - \sum_{i=1}^p \Phi_i B^i$ and $\Theta(B) = I_k - \sum_{i=1}^q \Theta_i B^i$.

Stationarity and Invertibility

For stationarity and invertibility of the VARMA process, the roots of $|\Phi(z)| = 0$ and $|\Theta(z)| = 0$ are outside the unit circle.

Parameter Estimation

Under the assumption of normality of the $\boldsymbol{\epsilon}_t$ with mean vector zero and nonsingular covariance matrix Σ , consider the conditional (approximate) log-likelihood function of a VARMA(p, q) model with mean zero.

Define $Y = (\mathbf{y}_1, \dots, \mathbf{y}_T)'$ and $E = (\boldsymbol{\epsilon}_1, \dots, \boldsymbol{\epsilon}_T)'$ with $B^i Y = (\mathbf{y}_{1-i}, \dots, \mathbf{y}_{T-i})'$ and $B^i E = (\boldsymbol{\epsilon}_{1-i}, \dots, \boldsymbol{\epsilon}_{T-i})'$; define $\mathbf{y} = \text{vec}(Y')$ and $\mathbf{e} = \text{vec}(E')$. Then

$$\mathbf{y} - \sum_{i=1}^p (I_T \otimes \Phi_i) B^i \mathbf{y} = \mathbf{e} - \sum_{i=1}^q (I_T \otimes \Theta_i) B^i \mathbf{e}$$

where $B^i \mathbf{y} = \text{vec}[(B^i Y)']$ and $B^i \mathbf{e} = \text{vec}[(B^i E)']$.

Then, the conditional (approximate) log-likelihood function can be written as follows (Reinsel 1997):

$$\begin{aligned}\ell &= -\frac{T}{2} \log |\Sigma| - \frac{1}{2} \sum_{t=1}^T \boldsymbol{\epsilon}_t' \Sigma^{-1} \boldsymbol{\epsilon}_t \\ &= -\frac{T}{2} \log |\Sigma| - \frac{1}{2} \mathbf{w}' \Theta^{-1} (I_T \otimes \Sigma^{-1}) \Theta^{-1} \mathbf{w}\end{aligned}$$

where $\mathbf{w} = \mathbf{y} - \sum_{i=1}^p (I_T \otimes \Phi_i) B^i \mathbf{y}$, and Θ is such that $\mathbf{e} - \sum_{i=1}^q (I_T \otimes \Theta_i) B^i \mathbf{e} = \Theta \mathbf{e}$.

For the exact log-likelihood function of a VARMA(p, q) model, the Kalman filtering method is used transforming the VARMA process into the state-space form (Reinsel 1997).

The state-space form of the VARMA(p, q) model consists of a state equation

$$\mathbf{z}_t = F \mathbf{z}_{t-1} + G \boldsymbol{\epsilon}_t$$

and an observation equation

$$\mathbf{y}_t = H \mathbf{z}_t$$

where for $v = \max(p, q + 1)$

$$\begin{aligned}\mathbf{z}_t &= (\mathbf{y}'_t, \mathbf{y}'_{t+1|t}, \dots, \mathbf{y}'_{t+v-1|t})' \\ F &= \begin{bmatrix} 0 & I_k & 0 & \cdots & 0 \\ 0 & 0 & I_k & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \Phi_v & \Phi_{v-1} & \Phi_{v-2} & \cdots & \Phi_1 \end{bmatrix}, \quad G = \begin{bmatrix} I_k \\ \Psi_1 \\ \vdots \\ \Psi_{v-1} \end{bmatrix}\end{aligned}$$

and

$$H = [I_k, 0, \dots, 0]$$

The Kalman filtering approach is used for evaluation of the likelihood function. The updating equation is

$$\hat{\mathbf{z}}_t|t = \hat{\mathbf{z}}_t|t-1 + K_t \boldsymbol{\epsilon}_t|t-1$$

with

$$K_t = P_t|t-1 H' [H P_t|t-1 H']^{-1}$$

and the prediction equation is

$$\hat{\mathbf{z}}_t|t-1 = F \hat{\mathbf{z}}_{t-1|t-1}, \quad P_t|t-1 = F P_{t-1|t-1} F' + G \Sigma G'$$

with $P_t|t = [I - K_t H] P_t|t-1$ for $t = 1, 2, \dots, n$.

The log-likelihood function can be expressed as

$$\ell = -\frac{1}{2} \sum_{t=1}^T [\log |\Sigma_{t|t-1}| - (\mathbf{y}_t - \hat{\mathbf{y}}_t|t-1)' \Sigma_{t|t-1}^{-1} (\mathbf{y}_t - \hat{\mathbf{y}}_t|t-1)]$$

where $\hat{\mathbf{y}}_{t|t-1}$ and $\Sigma_{t|t-1}$ are determined recursively from the Kalman filter procedure. To construct the likelihood function from Kalman filtering, you obtain $\hat{\mathbf{y}}_{t|t-1} = H\hat{\mathbf{z}}_{t|t-1}$, $\hat{\boldsymbol{\epsilon}}_{t|t-1} = \mathbf{y}_t - \hat{\mathbf{y}}_{t|t-1}$, and $\Sigma_{t|t-1} = HP_{t|t-1}H'$.

Define the vector $\boldsymbol{\beta}$

$$\boldsymbol{\beta} = (\phi'_1, \dots, \phi'_p, \theta'_1, \dots, \theta'_q, \text{vech}(\Sigma))'$$

where $\phi_i = \text{vec}(\Phi_i)$ and $\theta_i = \text{vec}(\Theta_i)$.

The log-likelihood equations are solved by iterative numerical procedures such as the quasi-Newton optimization. The starting values for the AR and MA parameters are obtained from the least squares estimates.

Asymptotic Distribution of the Parameter Estimates

Under the assumptions of stationarity and invertibility for the VARMA model and the assumption that $\boldsymbol{\epsilon}_t$ is a white noise process, $\hat{\boldsymbol{\beta}}$ is a consistent estimator for $\boldsymbol{\beta}$ and $\sqrt{T}(\hat{\boldsymbol{\beta}} - \boldsymbol{\beta})$ converges in distribution to the multivariate normal $N(0, V^{-1})$ as $T \rightarrow \infty$, where V is the asymptotic information matrix of $\boldsymbol{\beta}$.

Asymptotic Distributions of Impulse Response Functions

Defining the vector $\boldsymbol{\beta}$

$$\boldsymbol{\beta} = (\phi'_1, \dots, \phi'_p, \theta'_1, \dots, \theta'_q)'$$

the asymptotic distribution of the impulse response function for a VARMA(p, q) model is

$$\sqrt{T} \text{vec}(\hat{\Psi}_j - \Psi_j) \xrightarrow{d} N(0, G_j \Sigma_{\boldsymbol{\beta}} G'_j) \quad j = 1, 2, \dots$$

where $\Sigma_{\boldsymbol{\beta}}$ is the covariance matrix of the parameter estimates and

$$G_j = \frac{\partial \text{vec}(\Psi_j)}{\partial \boldsymbol{\beta}'} = \sum_{i=0}^{j-1} \mathbf{H}'(\mathbf{A}')^{j-1-i} \otimes \mathbf{J} \mathbf{A}^i \mathbf{J}'$$

where $\mathbf{H} = [I_k, 0, \dots, 0, I_k, 0, \dots, 0]'$ is a $k(p+q) \times k$ matrix with the second I_k following after p block matrices; $\mathbf{J} = [I_k, 0, \dots, 0]$ is a $k \times k(p+q)$ matrix; \mathbf{A} is a $k(p+q) \times k(p+q)$ matrix,

$$\mathbf{A} = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$$

where

$$A_{11} = \begin{bmatrix} \Phi_1 & \Phi_2 & \cdots & \Phi_{p-1} & \Phi_p \\ I_k & 0 & \cdots & 0 & 0 \\ 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & I_k & 0 \end{bmatrix} \quad A_{12} = \begin{bmatrix} -\Theta_1 & \cdots & -\Theta_{q-1} & -\Theta_q \\ 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 \end{bmatrix}$$

A_{21} is a $kq \times kp$ zero matrix, and

$$A_{22} = \begin{bmatrix} 0 & 0 & \cdots & 0 & 0 \\ I_k & 0 & \cdots & 0 & 0 \\ 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & I_k & 0 \end{bmatrix}$$

An Example of a VARMA(1,1) Model

Consider a VARMA(1,1) model with mean zero

$$\mathbf{y}_t = \Phi_1 \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t - \Theta_1 \boldsymbol{\epsilon}_{t-1}$$

where $\boldsymbol{\epsilon}_t$ is the white noise process with a mean zero vector and the positive-definite covariance matrix Σ .

The following IML procedure statements simulate a bivariate vector time series from this model to provide test data for the VARMAX procedure:

```
proc iml;
  sig = {1.0 0.5, 0.5 1.25};
  phi = {1.2 -0.5, 0.6 0.3};
  theta = {0.5 -0.2, 0.1 0.3};
  /* to simulate the vector time series */
  call varmasim(y,phi,theta) sigma=sig n=100 seed=34657;
  cn = {'y1' 'y2'};
  create simul3 from y[colname=cn];
  append from y;
run;
```

The following statements fit a VARMA(1,1) model to the simulated data. You specify the order of the autoregressive model with the P= option and the order of moving-average model with the Q= option. You specify the quasi-Newton optimization in the NLOPTIONS statement as an optimization method.

```
proc varmax data=simul3;
  nloptions tech=qn;
  model y1 y2 / p=1 q=1 noint print=(estimates);
run;
```

Figure 32.46 shows the initial values of parameters. The initial values were estimated using the least squares method.

VARMAX Modeling

A VARMAX(p, q, s) process is written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t - \sum_{i=1}^q \Theta_i \boldsymbol{\epsilon}_{t-i}$$

or

$$\Phi(B)\mathbf{y}_t = \boldsymbol{\delta} + \Theta^*(B)\mathbf{x}_t + \Theta(B)\boldsymbol{\epsilon}_t$$

where $\Phi(B) = I_k - \sum_{i=1}^p \Phi_i B^i$, $\Theta^*(B) = \Theta_0^* + \Theta_1^* B + \dots + \Theta_s^* B^s$, and $\Theta(B) = I_k - \sum_{i=1}^q \Theta_i B^i$.

The dimension of the state-space vector of the Kalman filtering method for the parameter estimation of the VARMAX(p, q, s) model is large, which takes time and memory for computing. For convenience, the parameter estimation of the VARMAX(p, q, s) model uses the two-stage estimation method, which first estimates the deterministic terms and exogenous parameters, and then maximizes the log-likelihood function of a VARMA(p, q) model.

Some examples of VARMAX modeling are as follows:

```
model y1 y2 = x1 / q=1;
nloptions tech=qn;
```

```
model y1 y2 = x1 / p=1 q=1 xlag=1 nocurrentx;
nloptions tech=qn;
```

Model Diagnostic Checks

Multivariate Model Diagnostic Checks

- Information Criterion After fitting some candidate models to the data, various model selection criteria (normalized by T) can be used to choose the appropriate model. The following list includes the Akaike information criterion (AIC), the corrected Akaike information criterion

(AICC), the final prediction error criterion (FPE), the Hannan-Quinn criterion (HQC), and the Schwarz Bayesian criterion (SBC, also referred to as BIC):

$$\begin{aligned} \text{AIC} &= \log(|\tilde{\Sigma}|) + 2r/T \\ \text{AICC} &= \log(|\tilde{\Sigma}|) + 2r/(T - r/k) \\ \text{FPE} &= \left(\frac{T + r/k}{T - r/k}\right)^k |\tilde{\Sigma}| \\ \text{HQC} &= \log(|\tilde{\Sigma}|) + 2r \log(\log(T))/T \\ \text{SBC} &= \log(|\tilde{\Sigma}|) + r \log(T)/T \end{aligned}$$

where r denotes the number of parameters estimated, k is the number of dependent variables, T is the number of observations used to estimate the model, and $\tilde{\Sigma}$ is the maximum likelihood estimate of Σ . When comparing models, choose the model with the smallest criterion values.

An example of the output was displayed in [Figure 32.4](#).

- **Portmanteau Q_s statistic** The Portmanteau Q_s statistic is used to test whether correlation remains on the model residuals. The null hypothesis is that the residuals are uncorrelated. Let $C_\epsilon(l)$ be the residual cross-covariance matrices, $\hat{\rho}_\epsilon(l)$ be the residual cross-correlation matrices as

$$C_\epsilon(l) = T^{-1} \sum_{t=1}^{T-l} \epsilon_t \epsilon'_{t+l}$$

and

$$\hat{\rho}_\epsilon(l) = \hat{V}_\epsilon^{-1/2} C_\epsilon(l) \hat{V}_\epsilon^{-1/2} \quad \text{and} \quad \hat{\rho}_\epsilon(-l) = \hat{\rho}_\epsilon(l)'$$

where $\hat{V}_\epsilon = \text{Diag}(\hat{\sigma}_{11}^2, \dots, \hat{\sigma}_{kk}^2)$ and $\hat{\sigma}_{ii}^2$ are the diagonal elements of $\hat{\Sigma}$. The multivariate portmanteau test defined in Hosking (1980) is

$$Q_s = T^2 \sum_{l=1}^s (T-l)^{-1} \text{tr}\{\hat{\rho}_\epsilon(l) \Sigma^{-1} \hat{\rho}_\epsilon(-l) \Sigma^{-1}\}$$

The statistic Q_s has approximately the chi-square distribution with $k^2(s - p - q)$ degrees of freedom. An example of the output is displayed in [Figure 32.7](#).

Univariate Model Diagnostic Checks

There are various ways to perform diagnostic checks for a univariate model. For details, see the section “Testing for Nonlinear Dependence: Heteroscedasticity Tests” on page 402 in Chapter 8, “The AUTOREG Procedure.” An example of the output is displayed in [Figure 32.8](#) and [Figure 32.9](#).

- **Durbin-Watson (DW) statistics:** The DW test statistics test for the first order autocorrelation in the residuals.

- Jarque-Bera normality test: This test is helpful in determining whether the model residuals represent a white noise process. This tests the null hypothesis that the residuals have normality.
- F tests for autoregressive conditional heteroscedastic (ARCH) disturbances: F test statistics test for the heteroscedastic disturbances in the residuals. This tests the null hypothesis that the residuals have equal covariances
- F tests for AR disturbance: These test statistics are computed from the residuals of the univariate AR(1), AR(1,2), AR(1,2,3) and AR(1,2,3,4) models to test the null hypothesis that the residuals are uncorrelated.

Cointegration

This section briefly introduces the concepts of cointegration (Johansen 1995b).

Definition 1. (Engle and Granger 1987): *If a series y_t with no deterministic components can be represented by a stationary and invertible ARMA process after differencing d times, the series is integrated of order d , that is, $y_t \sim I(d)$.*

Definition 2. (Engle and Granger 1987): *If all elements of the vector \mathbf{y}_t are $I(d)$ and there exists a cointegrating vector $\boldsymbol{\beta} \neq 0$ such that $\boldsymbol{\beta}'\mathbf{y}_t \sim I(d - b)$ for any $b > 0$, the vector process is said to be cointegrated $CI(d, b)$.*

A simple example of a cointegrated process is the following bivariate system:

$$\begin{aligned} y_{1t} &= \gamma y_{2t} + \epsilon_{1t} \\ y_{2t} &= y_{2,t-1} + \epsilon_{2t} \end{aligned}$$

with ϵ_{1t} and ϵ_{2t} being uncorrelated white noise processes. In the second equation, y_{2t} is a random walk, $\Delta y_{2t} = \epsilon_{2t}$, $\Delta \equiv 1 - B$. Differencing the first equation results in

$$\Delta y_{1t} = \gamma \Delta y_{2t} + \Delta \epsilon_{1t} = \gamma \epsilon_{2t} + \epsilon_{1t} - \epsilon_{1,t-1}$$

Thus, both y_{1t} and y_{2t} are $I(1)$ processes, but the linear combination $y_{1t} - \gamma y_{2t}$ is stationary. Hence $\mathbf{y}_t = (y_{1t}, y_{2t})'$ is cointegrated with a cointegrating vector $\boldsymbol{\beta} = (1, -\gamma)'$.

In general, if the vector process \mathbf{y}_t has k components, then there can be more than one cointegrating vector $\boldsymbol{\beta}'$. It is assumed that there are r linearly independent cointegrating vectors with $r < k$, which make the $k \times r$ matrix $\boldsymbol{\beta}$. The rank of matrix $\boldsymbol{\beta}$ is r , which is called the *cointegration rank* of \mathbf{y}_t .

Common Trends

This section briefly discusses the implication of cointegration for the moving-average representation. Let \mathbf{y}_t be cointegrated $CI(1, 1)$, then $\Delta \mathbf{y}_t$ has the Wold representation:

$$\Delta \mathbf{y}_t = \boldsymbol{\delta} + \Psi(B)\boldsymbol{\epsilon}_t$$

where ϵ_t is $iid(0, \Sigma)$, $\Psi(B) = \sum_{j=0}^{\infty} \Psi_j B^j$ with $\Psi_0 = I_k$, and $\sum_{j=0}^{\infty} j |\Psi_j| < \infty$.

Assume that $\epsilon_t = 0$ if $t \leq 0$ and \mathbf{y}_0 is a nonrandom initial value. Then the difference equation implies that

$$\mathbf{y}_t = \mathbf{y}_0 + \delta t + \Psi(1) \sum_{i=0}^t \epsilon_i + \Psi^*(B) \epsilon_t$$

where $\Psi^*(B) = (1 - B)^{-1}(\Psi(B) - \Psi(1))$ and $\Psi^*(B)$ is absolutely summable.

Assume that the rank of $\Psi(1)$ is $m = k - r$. When the process \mathbf{y}_t is cointegrated, there is a cointegrating $k \times r$ matrix β such that $\beta' \mathbf{y}_t$ is stationary.

Premultiplying \mathbf{y}_t by β' results in

$$\beta' \mathbf{y}_t = \beta' \mathbf{y}_0 + \beta' \Psi^*(B) \epsilon_t$$

because $\beta' \Psi(1) = 0$ and $\beta' \delta = 0$.

Stock and Watson (1988) showed that the cointegrated process \mathbf{y}_t has a common trends representation derived from the moving-average representation. Since the rank of $\Psi(1)$ is $m = k - r$, there is a $k \times r$ matrix H_1 with rank r such that $\Psi(1)H_1 = 0$. Let H_2 be a $k \times m$ matrix with rank m such that $H_2' H_1 = 0$; then $A = C(1)H_2$ has rank m . The $H = (H_1, H_2)$ has rank k . By construction of H ,

$$\Psi(1)H = [0, A] = AS_m$$

where $S_m = (0_{m \times r}, I_m)$. Since $\beta' \Psi(1) = 0$ and $\beta' \delta = 0$, δ lies in the column space of $\Psi(1)$ and can be written

$$\delta = C(1)\tilde{\delta}$$

where $\tilde{\delta}$ is a k -dimensional vector. The common trends representation is written as

$$\begin{aligned} \mathbf{y}_t &= \mathbf{y}_0 + \Psi(1)[\tilde{\delta}t + \sum_{i=0}^t \epsilon_i] + \Psi^*(B)\epsilon_t \\ &= \mathbf{y}_0 + \Psi(1)H[H^{-1}\tilde{\delta}t + H^{-1}\sum_{i=0}^t \epsilon_i] + \mathbf{a}_t \\ &= \mathbf{y}_0 + A\tau_t + \mathbf{a}_t \end{aligned}$$

and

$$\tau_t = \pi + \tau_{t-1} + \mathbf{v}_t$$

where $\mathbf{a}_t = \Psi^*(B)\epsilon_t$, $\pi = S_m H^{-1}\tilde{\delta}$, $\tau_t = S_m[H^{-1}\tilde{\delta}t + H^{-1}\sum_{i=0}^t \epsilon_i]$, and $\mathbf{v}_t = S_m H^{-1}\epsilon_t$.

Stock and Watson showed that the common trends representation expresses \mathbf{y}_t as a linear combination of m random walks (τ_t) with drift π plus $I(0)$ components (\mathbf{a}_t).

Test for the Common Trends

Stock and Watson (1988) proposed statistics for common trends testing. The null hypothesis is that the k -dimensional time series \mathbf{y}_t has m common stochastic trends, where $m \leq k$ and the alternative is that it has s common trends, where $s < m$. The test procedure of m versus s common stochastic trends is performed based on the first-order serial correlation matrix of \mathbf{y}_t . Let β_{\perp} be a $k \times m$ matrix orthogonal to the cointegrating matrix such that $\beta_{\perp}'\beta = 0$ and $\beta_{\perp}\beta_{\perp}' = I_m$. Let $\mathbf{z}_t = \beta'\mathbf{y}_t$ and $\mathbf{w}_t = \beta_{\perp}'\mathbf{y}_t$. Then

$$\mathbf{w}_t = \beta_{\perp}'\mathbf{y}_0 + \beta_{\perp}'\delta t + \beta_{\perp}'\Psi(1) \sum_{i=0}^t \epsilon_i + \beta_{\perp}'\Psi^*(B)\epsilon_t$$

Combining the expression of \mathbf{z}_t and \mathbf{w}_t ,

$$\begin{bmatrix} \mathbf{z}_t \\ \mathbf{w}_t \end{bmatrix} = \begin{bmatrix} \beta'\mathbf{y}_0 \\ \beta_{\perp}'\mathbf{y}_0 \end{bmatrix} + \begin{bmatrix} 0 \\ \beta_{\perp}'\delta \end{bmatrix} t + \begin{bmatrix} 0 \\ \beta_{\perp}'\Psi(1) \end{bmatrix} \sum_{i=1}^t \epsilon_i + \begin{bmatrix} \beta'\Psi^*(B) \\ \beta_{\perp}'\Psi^*(B) \end{bmatrix} \epsilon_t$$

The Stock-Watson common trends test is performed based on the component \mathbf{w}_t by testing whether $\beta_{\perp}'\Psi(1)$ has rank m against rank s .

The following statements perform the Stock-Watson test for common trends:

```
proc iml;
  sig = 100*i(2);
  phi = {-0.2 0.1, 0.5 0.2, 0.8 0.7, -0.4 0.6};
  call varmasim(y,phi) sigma=sig n=100 initial=0
              seed=45876;

  cn = {'y1' 'y2'};
  create simul2 from y[colname=cn];
  append from y;
quit;

data simul2;
  set simul2;
  date = intnx('year', '01jan1900'd, _n_-1);
  format date year4. ;
run;

proc varmax data=simul2;
  model y1 y2 / p=2 cointtest=(sw);
run;
```

In Figure 32.51, the first column is the null hypothesis that \mathbf{y}_t has $m \leq k$ common trends; the second column is the alternative hypothesis that \mathbf{y}_t has $s < m$ common trends; the third column contains the eigenvalues used for the test statistics; the fourth column contains the test statistics using $AR(p)$ filtering of the data. The table shows the output of the case $p = 2$.

Figure 32.51 Common Trends Test (COINTTEST=(SW) Option)

The VARMAX Procedure						
Common Trend Test						
H0:	H1:	Eigenvalue	Filter	5% Critical Value	Lag	
Rank=m	Rank=s					
1	0	1.000906	0.09	-14.10	2	
2	0	0.996763	-0.32	-8.80		
	1	0.648908	-35.11	-23.00		

The test statistic for testing for 2 versus 1 common trends is more negative (-35.1) than the critical value (-23.0). Therefore, the test rejects the null hypothesis, which means that the series has a single common trend.

Vector Error Correction Modeling

This section discusses the implication of cointegration for the autoregressive representation. Assume that the cointegrated series can be represented by a vector error correction model according to the Granger representation theorem (Engle and Granger 1987). Consider the vector autoregressive process with Gaussian errors defined by

$$\mathbf{y}_t = \sum_{i=1}^p \Phi_i \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

or

$$\Phi(B)\mathbf{y}_t = \boldsymbol{\epsilon}_t$$

where the initial values, $\mathbf{y}_{-p+1}, \dots, \mathbf{y}_0$, are fixed and $\boldsymbol{\epsilon}_t \sim N(0, \Sigma)$. Since the AR operator $\Phi(B)$ can be re-expressed as $\Phi(B) = \Phi^*(B)(1 - B) + \Phi(1)B$, where $\Phi^*(B) = I_k - \sum_{i=1}^{p-1} \Phi_i^* B^i$ with $\Phi_i^* = -\sum_{j=i+1}^p \Phi_j$, the vector error correction model is

$$\Phi^*(B)(1 - B)\mathbf{y}_t = \boldsymbol{\alpha}\boldsymbol{\beta}'\mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

or

$$\Delta\mathbf{y}_t = \boldsymbol{\alpha}\boldsymbol{\beta}'\mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta\mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

where $\boldsymbol{\alpha}\boldsymbol{\beta}' = -\Phi(1) = -I_k + \Phi_1 + \Phi_2 + \dots + \Phi_p$.

One motivation for the $VECM(p)$ form is to consider the relation $\beta' \mathbf{y}_t = \mathbf{c}$ as defining the underlying economic relations and assume that the agents react to the disequilibrium error $\beta' \mathbf{y}_t - \mathbf{c}$ through the adjustment coefficient α to restore equilibrium; that is, they satisfy the economic relations. The cointegrating vector, β is sometimes called the *long-run parameters*.

You can consider a vector error correction model with a deterministic term. The deterministic term D_t can contain a constant, a linear trend, and seasonal dummy variables. Exogenous variables can also be included in the model.

$$\Delta \mathbf{y}_t = \Pi \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + AD_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \epsilon_t$$

where $\Pi = \alpha \beta'$.

The alternative vector error correction representation considers the error correction term at lag $t - p$ and is written as

$$\Delta \mathbf{y}_t = \sum_{i=1}^{p-1} \Phi_i^\# \Delta \mathbf{y}_{t-i} + \Pi^\# \mathbf{y}_{t-p} + AD_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \epsilon_t$$

If the matrix Π has a full-rank ($r = k$), all components of \mathbf{y}_t are $I(0)$. On the other hand, \mathbf{y}_t are stationary in difference if $\text{rank}(\Pi) = 0$. When the rank of the matrix Π is $r < k$, there are $k - r$ linear combinations that are nonstationary and r stationary cointegrating relations. Note that the linearly independent vector $\mathbf{z}_t = \beta' \mathbf{y}_t$ is stationary and this transformation is not unique unless $r = 1$. There does not exist a unique cointegrating matrix β since the coefficient matrix Π can also be decomposed as

$$\Pi = \alpha M M^{-1} \beta' = \alpha^* \beta^{*'}$$

where M is an $r \times r$ nonsingular matrix.

Test for the Cointegration

The cointegration rank test determines the linearly independent columns of Π . Johansen (1988, 1995a) and Johansen and Juselius (1990) proposed the cointegration rank test by using the reduced rank regression.

Different Specifications of Deterministic Trends

When you construct the $VECM(p)$ form from the $VAR(p)$ model, the deterministic terms in the $VECM(p)$ form can differ from those in the $VAR(p)$ model. When there are deterministic cointegrated relationships among variables, deterministic terms in the $VAR(p)$ model are not present in the $VECM(p)$ form. On the other hand, if there are stochastic cointegrated relationships in the $VAR(p)$ model, deterministic terms appear in the $VECM(p)$ form via the error correction term or as an independent term in the $VECM(p)$ form. There are five different specifications of deterministic trends in the $VECM(p)$ form.

- **Case 1:** There is no separate drift in the VECM(p) form.

$$\Delta \mathbf{y}_t = \alpha \beta' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \epsilon_t$$

- **Case 2:** There is no separate drift in the VECM(p) form, but a constant enters only via the error correction term.

$$\Delta \mathbf{y}_t = \alpha (\beta', \beta_0) (\mathbf{y}'_{t-1}, 1)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \epsilon_t$$

- **Case 3:** There is a separate drift and no separate linear trend in the VECM(p) form.

$$\Delta \mathbf{y}_t = \alpha \beta' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \delta_0 + \epsilon_t$$

- **Case 4:** There is a separate drift and no separate linear trend in the VECM(p) form, but a linear trend enters only via the error correction term.

$$\Delta \mathbf{y}_t = \alpha (\beta', \beta_1) (\mathbf{y}'_{t-1}, t)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \delta_0 + \epsilon_t$$

- **Case 5:** There is a separate linear trend in the VECM(p) form.

$$\Delta \mathbf{y}_t = \alpha \beta' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \delta_0 + \delta_1 t + \epsilon_t$$

First, focus on Cases 1, 3, and 5 to test the null hypothesis that there are at most r cointegrating vectors. Let

$$\begin{aligned} Z_{0t} &= \Delta \mathbf{y}_t \\ Z_{1t} &= \mathbf{y}_{t-1} \\ Z_{2t} &= [\Delta \mathbf{y}'_{t-1}, \dots, \Delta \mathbf{y}'_{t-p+1}, D_t]' \\ Z_0 &= [Z_{01}, \dots, Z_{0T}]' \\ Z_1 &= [Z_{11}, \dots, Z_{1T}]' \\ Z_2 &= [Z_{21}, \dots, Z_{2T}]' \end{aligned}$$

where D_t can be empty for Case 1, 1 for Case 3, and $(1, t)$ for Case 5.

In Case 2, Z_{1t} and Z_{2t} are defined as

$$\begin{aligned} Z_{1t} &= [\mathbf{y}'_{t-1}, 1]' \\ Z_{2t} &= [\Delta \mathbf{y}'_{t-1}, \dots, \Delta \mathbf{y}'_{t-p+1}]' \end{aligned}$$

In Case 4, Z_{1t} and Z_{2t} are defined as

$$\begin{aligned} Z_{1t} &= [\mathbf{y}'_{t-1}, t]' \\ Z_{2t} &= [\Delta \mathbf{y}'_{t-1}, \dots, \Delta \mathbf{y}'_{t-p+1}, 1]' \end{aligned}$$

Let Ψ be the matrix of parameters consisting of $\Phi_1^*, \dots, \Phi_{p-1}^*$, A , and $\Theta_0^*, \dots, \Theta_s^*$, where parameters A corresponds to regressors D_t . Then the VECM(p) form is rewritten in these variables as

$$Z_{0t} = \alpha \beta' Z_{1t} + \Psi Z_{2t} + \epsilon_t$$

The log-likelihood function is given by

$$\begin{aligned} \ell &= -\frac{kT}{2} \log 2\pi - \frac{T}{2} \log |\Sigma| \\ &\quad - \frac{1}{2} \sum_{t=1}^T (Z_{0t} - \alpha \beta' Z_{1t} - \Psi Z_{2t})' \Sigma^{-1} (Z_{0t} - \alpha \beta' Z_{1t} - \Psi Z_{2t}) \end{aligned}$$

The residuals, R_{0t} and R_{1t} , are obtained by regressing Z_{0t} and Z_{1t} on Z_{2t} , respectively. The regression equation of residuals is

$$R_{0t} = \alpha \beta' R_{1t} + \hat{\epsilon}_t$$

The crossproducts matrices are computed

$$S_{ij} = \frac{1}{T} \sum_{t=1}^T R_{it} R'_{jt}, \quad i, j = 0, 1$$

Then the maximum likelihood estimator for β is obtained from the eigenvectors that correspond to the r largest eigenvalues of the following equation:

$$|\lambda S_{11} - S_{10} S_{00}^{-1} S_{01}| = 0$$

The eigenvalues of the preceding equation are squared canonical correlations between R_{0t} and R_{1t} , and the eigenvectors that correspond to the r largest eigenvalues are the r linear combinations of \mathbf{y}_{t-1} , which have the largest squared partial correlations with the stationary process $\Delta \mathbf{y}_t$ after correcting for lags and deterministic terms. Such an analysis calls for a reduced rank regression of $\Delta \mathbf{y}_t$ on \mathbf{y}_{t-1} corrected for $(\Delta \mathbf{y}_{t-1}, \dots, \Delta \mathbf{y}_{t-p+1}, D_t)$, as discussed by Anderson (1951). Johansen (1988) suggests two test statistics to test the null hypothesis that there are at most r cointegrating vectors

$$H_0 : \lambda_i = 0 \text{ for } i = r + 1, \dots, k$$

Trace Test

The trace statistic for testing the null hypothesis that there are at most r cointegrating vectors is as follows:

$$\lambda_{trace} = -T \sum_{i=r+1}^k \log(1 - \lambda_i)$$

The asymptotic distribution of this statistic is given by

$$tr \left\{ \int_0^1 (dW) \tilde{W}' \left(\int_0^1 \tilde{W} \tilde{W}' dr \right)^{-1} \int_0^1 \tilde{W} (dW)' \right\}$$

where $tr(A)$ is the trace of a matrix A , W is the $k - r$ dimensional Brownian motion, and \tilde{W} is the Brownian motion itself, or the demeaned or detrended Brownian motion according to the different specifications of deterministic trends in the vector error correction model.

Maximum Eigenvalue Test

The maximum eigenvalue statistic for testing the null hypothesis that there are at most r cointegrating vectors is as follows:

$$\lambda_{max} = -T \log(1 - \lambda_{r+1})$$

The asymptotic distribution of this statistic is given by

$$max \left\{ \int_0^1 (dW) \tilde{W}' \left(\int_0^1 \tilde{W} \tilde{W}' dr \right)^{-1} \int_0^1 \tilde{W} (dW)' \right\}$$

where $max(A)$ is the maximum eigenvalue of a matrix A . Osterwald-Lenum (1992) provided detailed tables of the critical values of these statistics.

The following statements use the JOHANSEN option to compute the Johansen cointegration rank trace test of integrated order 1:

```
proc varmax data=simul2;
  model y1 y2 / p=2 cointtest=(johansen=(normalize=y1));
run;
```

Figure 32.52 shows the output based on the model specified in the MODEL statement, an intercept term is assumed. In the “Cointegration Rank Test Using Trace” table, the column Drift In ECM means there is no separate drift in the error correction model and the column Drift In Process means the process has a constant drift before differencing. The “Cointegration Rank Test Using Trace” table shows the trace statistics based on Case 3 and the “Cointegration Rank Test Using Trace under Restriction” table shows the trace statistics based on Case 2. The output indicates that the series are cointegrated with rank 1 because the trace statistics are smaller than the critical values in both Case 2 and Case 3.

Figure 32.52 Cointegration Rank Test (COINTTEST=(JOHANSEN=) Option)

The VARMAX Procedure						
Cointegration Rank Test Using Trace						
H0:	H1:	Eigenvalue	Trace	5%	Drift in ECM	Drift in Process
Rank=r	Rank>r			Critical Value		
0	0	0.4644	61.7522	15.34	Constant	Linear
1	1	0.0056	0.5552	3.84		

Cointegration Rank Test Using Trace Under Restriction						
H0:	H1:	Eigenvalue	Trace	5%	Drift in ECM	Drift in Process
Rank=r	Rank>r			Critical Value		
0	0	0.5209	76.3788	19.99	Constant	Constant
1	1	0.0426	4.2680	9.13		

Figure 32.53 shows which result, either Case 2 (the hypothesis H0) or Case 3 (the hypothesis H1), is appropriate depending on the significance level. Since the cointegration rank is chosen to be 1 by the result in Figure 32.52, look at the last row that corresponds to rank=1. Since the p -value is 0.054, the Case 2 cannot be rejected at the significance level 5%, but it can be rejected at the significance level 10%. For modeling of the two Case 2 and Case 3, see Figure 32.56 and Figure 32.57.

Figure 32.53 Cointegration Rank Test Continued

Variable	1	2
y1	1.00000	1.00000
y2	-2.04366	-2.75773
1	6.75919	101.37051
Alpha Under Restriction		
Variable	1	2
y1	-0.48015	0.01091
y2	0.12538	0.03722

Considering that the cointegration rank is 1, the long-run relationship of the series is

$$\begin{aligned}\beta' y_t &= \begin{bmatrix} 1 & -2.04366 & 6.75919 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ 1 \end{bmatrix} \\ &= y_{1t} - 2.04366 y_{2t} + 6.75919 \\ y_{1t} &= 2.04366 y_{2t} - 6.75919\end{aligned}$$

Estimation of Vector Error Correction Model

The preceding log-likelihood function is maximized for

$$\begin{aligned}\hat{\beta} &= S_{11}^{-1/2} [v_1, \dots, v_r] \\ \hat{\alpha} &= S_{01} \hat{\beta} (\hat{\beta}' S_{11} \hat{\beta})^{-1} \\ \hat{\Pi} &= \hat{\alpha} \hat{\beta}' \\ \hat{\Psi}' &= (Z_2' Z_2)^{-1} Z_2' (Z_0 - Z_1 \hat{\Pi}') \\ \hat{\Sigma} &= (Z_0 - Z_2 \hat{\Psi}' - Z_1 \hat{\Pi}')' (Z_0 - Z_2 \hat{\Psi}' - Z_1 \hat{\Pi}') / T\end{aligned}$$

The estimators of the orthogonal complements of α and β are

$$\hat{\beta}_\perp = S_{11} [v_{r+1}, \dots, v_k]$$

and

$$\hat{\alpha}_\perp = S_{00}^{-1} S_{01} [v_{r+1}, \dots, v_k]$$

The ML estimators have the following asymptotic properties:

$$\sqrt{T} \text{vec}([\hat{\Pi}, \hat{\Psi}] - [\Pi, \Psi]) \xrightarrow{d} N(0, \Sigma_{co})$$

where

$$\Sigma_{co} = \Sigma \otimes \left(\begin{bmatrix} \beta & 0 \\ 0 & I_k \end{bmatrix} \Omega^{-1} \begin{bmatrix} \beta' & 0 \\ 0 & I_k \end{bmatrix} \right)$$

and

$$\Omega = \text{plim} \frac{1}{T} \begin{bmatrix} \beta' Z_1' Z_1 \beta & \beta' Z_1' Z_2 \\ Z_2' Z_1 \beta & Z_2' Z_2 \end{bmatrix}$$

The following statements are examples of fitting the five different cases of the vector error correction models mentioned in the previous section.

For fitting Case 1,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1) noint;
```

For fitting Case 2,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1 ectrend);
```

For fitting Case 3,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1);
```

For fitting Case 4,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1 ectrend)
trend=linear;
```

For fitting Case 5,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1) trend=linear;
```

From [Figure 32.53](#) that uses the COINTTEST=(JOHANSEN) option, you can fit the model by using either Case 2 or Case 3 because the test was not significant at the 0.05 level, but was significant at the 0.10 level. Here both models are fitted to show the difference in output display. [Figure 32.56](#) is for Case 2, and [Figure 32.57](#) is for Case 3.

For Case 2,

```
proc varmax data=simul2;
  model y1 y2 / p=2 ecm=(rank=1 normalize=y1 ectrend)
    print=(estimates);
run;
```

Test for the Linear Restriction on the Parameters

Consider the example with the variables m_t log real money, y_t log real income, i_t^d deposit interest rate, and i_t^b bond interest rate. It seems a natural hypothesis that in the long-run relation, money and income have equal coefficients with opposite signs. This can be formulated as the hypothesis that the cointegrated relation contains only m_t and y_t through $m_t - y_t$. For the analysis, you can express these restrictions in the parameterization of H such that $\boldsymbol{\beta} = H\boldsymbol{\phi}$, where H is a known $k \times s$ matrix

and ψ is the $s \times r$ ($r \leq s < k$) parameter matrix to be estimated. For this example, H is given by

$$H = \begin{bmatrix} 1 & 0 & 0 \\ -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Restriction $H_0: \beta = H\phi$

When the linear restriction $\beta = H\phi$ is given, it implies that the same restrictions are imposed on all cointegrating vectors. You obtain the maximum likelihood estimator of β by reduced rank regression of $\Delta \mathbf{y}_t$ on $H \mathbf{y}_{t-1}$ corrected for $(\Delta \mathbf{y}_{t-1}, \dots, \Delta \mathbf{y}_{t-p+1}, D_t)$, solving the following equation

$$|\rho H' S_{11} H - H' S_{10} S_{00}^{-1} S_{01} H| = 0$$

for the eigenvalues $1 > \rho_1 > \dots > \rho_s > 0$ and eigenvectors (v_1, \dots, v_s) , S_{ij} given in the preceding section. Then choose $\hat{\phi} = (v_1, \dots, v_r)$ that corresponds to the r largest eigenvalues, and the $\hat{\beta}$ is $H\hat{\phi}$.

The test statistic for $H_0: \beta = H\phi$ is given by

$$T \sum_{i=1}^r \log\{(1 - \rho_i)/(1 - \lambda_i)\} \xrightarrow{d} \chi_{r(k-s)}^2$$

If the series has no deterministic trend, the constant term should be restricted by $\alpha'_1 \delta_0 = 0$ as in Case 2. Then H is given by

$$H = \begin{bmatrix} 1 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

The following statements test that $2\beta_1 + \beta_2 = 0$:

```
proc varmax data=simul2;
  model y1 y2 / p=2 ecm=(rank=1 normalize=y1);
  cointeg rank=1 h=(1,-2);
run;
```

Figure 32.58 shows the results of testing $H_0: 2\beta_1 + \beta_2 = 0$. The input H matrix is $H = (1 - 2)'$. The adjustment coefficient is reestimated under the restriction, and the test indicates that you cannot reject the null hypothesis.

Test for the Weak Exogeneity and Restrictions of Alpha

Consider a vector error correction model:

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha} \boldsymbol{\beta}' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + A D_t + \boldsymbol{\epsilon}_t$$

Divide the process \mathbf{y}_t into $(\mathbf{y}'_{1t}, \mathbf{y}'_{2t})'$ with dimension k_1 and k_2 and the Σ into

$$\Sigma = \begin{bmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix}$$

Similarly, the parameters can be decomposed as follows:

$$\boldsymbol{\alpha} = \begin{bmatrix} \boldsymbol{\alpha}_1 \\ \boldsymbol{\alpha}_2 \end{bmatrix} \quad \Phi_i^* = \begin{bmatrix} \Phi_{1i}^* \\ \Phi_{2i}^* \end{bmatrix} \quad A = \begin{bmatrix} A_1 \\ A_2 \end{bmatrix}$$

Then the VECM(p) form can be rewritten by using the decomposed parameters and processes:

$$\begin{bmatrix} \Delta \mathbf{y}_{1t} \\ \Delta \mathbf{y}_{2t} \end{bmatrix} = \begin{bmatrix} \boldsymbol{\alpha}_1 \\ \boldsymbol{\alpha}_2 \end{bmatrix} \boldsymbol{\beta}' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \begin{bmatrix} \Phi_{1i}^* \\ \Phi_{2i}^* \end{bmatrix} \Delta \mathbf{y}_{t-i} + \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} D_t + \begin{bmatrix} \boldsymbol{\epsilon}_{1t} \\ \boldsymbol{\epsilon}_{2t} \end{bmatrix}$$

The conditional model for \mathbf{y}_{1t} given \mathbf{y}_{2t} is

$$\begin{aligned}\Delta \mathbf{y}_{1t} &= \omega \Delta \mathbf{y}_{2t} + (\alpha_1 - \omega \alpha_2) \boldsymbol{\beta}' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} (\Phi_{1i}^* - \omega \Phi_{2i}^*) \Delta \mathbf{y}_{t-i} \\ &\quad + (A_1 - \omega A_2) D_t + \boldsymbol{\epsilon}_{1t} - \omega \boldsymbol{\epsilon}_{2t}\end{aligned}$$

and the marginal model of \mathbf{y}_{2t} is

$$\Delta \mathbf{y}_{2t} = \alpha_2 \boldsymbol{\beta}' \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_{2i}^* \Delta \mathbf{y}_{t-i} + A_2 D_t + \boldsymbol{\epsilon}_{2t}$$

where $\omega = \Sigma_{12} \Sigma_{22}^{-1}$.

The test of weak exogeneity of \mathbf{y}_{2t} for the parameters $(\alpha_1, \boldsymbol{\beta})$ determines whether $\alpha_2 = 0$. Weak exogeneity means that there is no information about $\boldsymbol{\beta}$ in the marginal model or that the variables \mathbf{y}_{2t} do not react to a disequilibrium.

Restriction $H_0: \boldsymbol{\alpha} = J\boldsymbol{\psi}$

Consider the null hypothesis $H_0: \boldsymbol{\alpha} = J\boldsymbol{\psi}$, where J is a $k \times m$ matrix with $r \leq m < k$.

From the previous residual regression equation

$$R_{0t} = \boldsymbol{\alpha} \boldsymbol{\beta}' R_{1t} + \hat{\boldsymbol{\epsilon}}_t = J\boldsymbol{\psi} \boldsymbol{\beta}' R_{1t} + \hat{\boldsymbol{\epsilon}}_t$$

you can obtain

$$\begin{aligned}\bar{J}' R_{0t} &= \boldsymbol{\psi} \boldsymbol{\beta}' R_{1t} + \bar{J}' \hat{\boldsymbol{\epsilon}}_t \\ J_{\perp}' R_{0t} &= J_{\perp}' \hat{\boldsymbol{\epsilon}}_t\end{aligned}$$

where $\bar{J} = J(J'J)^{-1}$ and J_{\perp} is orthogonal to J such that $J_{\perp}'J = 0$.

Define

$$\Sigma_{JJ_{\perp}} = \bar{J}' \Sigma J_{\perp} \text{ and } \Sigma_{J_{\perp}J_{\perp}} = J_{\perp}' \Sigma J_{\perp}$$

and let $\omega = \Sigma_{JJ_{\perp}} \Sigma_{J_{\perp}J_{\perp}}^{-1}$. Then $\bar{J}' R_{0t}$ can be written as

$$\bar{J}' R_{0t} = \boldsymbol{\psi} \boldsymbol{\beta}' R_{1t} + \omega J_{\perp}' R_{0t} + \bar{J}' \hat{\boldsymbol{\epsilon}}_t - \omega J_{\perp}' \hat{\boldsymbol{\epsilon}}_t$$

Using the marginal distribution of $J_{\perp}' R_{0t}$ and the conditional distribution of $\bar{J}' R_{0t}$, the new residuals are computed as

$$\begin{aligned}\tilde{R}_{Jt} &= \bar{J}' R_{0t} - S_{JJ_{\perp}} S_{J_{\perp}J_{\perp}}^{-1} J_{\perp}' R_{0t} \\ \tilde{R}_{1t} &= R_{1t} - S_{1J_{\perp}} S_{J_{\perp}J_{\perp}}^{-1} J_{\perp}' R_{0t}\end{aligned}$$

where

$$S_{JJ_{\perp}} = \bar{J}' S_{00} J_{\perp}, \quad S_{J_{\perp} J_{\perp}} = J'_{\perp} S_{00} J_{\perp}, \quad \text{and} \quad S_{J_{\perp} 1} = J'_{\perp} S_{01}$$

In terms of \tilde{R}_{Jt} and \tilde{R}_{1t} , the MLE of β is computed by using the reduced rank regression. Let

$$S_{ij.J_{\perp}} = \frac{1}{T} \sum_{t=1}^T \tilde{R}_{it} \tilde{R}'_{jt}, \quad \text{for } i, j = 1, J$$

Under the null hypothesis $H_0: \alpha = J\psi$, the MLE $\tilde{\beta}$ is computed by solving the equation

$$|\rho S_{11.J_{\perp}} - S_{1J.J_{\perp}} S_{JJ.J_{\perp}}^{-1} S_{J1.J_{\perp}}| = 0$$

Then $\tilde{\beta} = (v_1, \dots, v_r)$, where the eigenvectors correspond to the r largest eigenvalues. The likelihood ratio test for $H_0: \alpha = J\psi$ is

$$T \sum_{i=1}^r \log\{(1 - \rho_i)/(1 - \lambda_i)\} \xrightarrow{d} \chi^2_{r(k-m)}$$

The test of weak exogeneity of y_{2t} is a special case of the test $\alpha = J\psi$, considering $J = (I_{k_1}, 0)'$. Consider the previous example with four variables (m_t, y_t, i_t^b, i_t^d) . If $r = 1$, you formulate the weak exogeneity of (y_t, i_t^b, i_t^d) for m_t as $J = [1, 0, 0, 0]'$ and the weak exogeneity of i_t^d for (m_t, y_t, i_t^b) as $J = [I_3, 0]'$.

The following statements test the weak exogeneity of other variables, assuming $r = 1$:

```
proc varmax data=simul2;
  model y1 y2 / p=2 ecm=(rank=1 normalize=y1);
  cointeg rank=1 exogeneity;
run;

proc varmax data=simul2;
  model y1 y2 / p=2 ecm=(rank=1 normalize=y1);
  cointeg rank=1 j=exogeneity;
run;
```

Figure 32.59 shows that each variable is not the weak exogeneity of other variable.

Figure 32.59 Testing of Weak Exogeneity (EXOGENEITY Option)

The VARMAX Procedure			
Testing Weak Exogeneity of Each Variables			
Variable	DF	Chi-Square	Pr > ChiSq
y1	1	53.46	<.0001
y2	1	8.76	0.0031

Forecasting of the VECM

Consider the cointegrated moving-average representation of the differenced process of \mathbf{y}_t

$$\Delta \mathbf{y}_t = \boldsymbol{\delta} + \Psi(B)\boldsymbol{\epsilon}_t$$

Assume that $\mathbf{y}_0 = 0$. The linear process \mathbf{y}_t can be written as

$$\mathbf{y}_t = \boldsymbol{\delta}t + \sum_{i=1}^t \sum_{j=0}^{t-i} \Psi_j \boldsymbol{\epsilon}_i$$

Therefore, for any $l > 0$,

$$\mathbf{y}_{t+l} = \boldsymbol{\delta}(t+l) + \sum_{i=1}^t \sum_{j=0}^{t+l-i} \Psi_j \boldsymbol{\epsilon}_i + \sum_{i=1}^l \sum_{j=0}^{l-i} \Psi_j \boldsymbol{\epsilon}_{t+i}$$

The l -step-ahead forecast is derived from the preceding equation:

$$\mathbf{y}_{t+l|t} = (t+l)\boldsymbol{\delta} + \sum_{i=1}^t \sum_{j=0}^{t+l-i} \Psi_j \boldsymbol{\epsilon}_i$$

Note that

$$\lim_{l \rightarrow \infty} \boldsymbol{\beta}' \mathbf{y}_{t+l|t} = 0$$

since $\lim_{l \rightarrow \infty} \sum_{j=0}^{t+l-i} \Psi_j = \Psi(1)$ and $\boldsymbol{\beta}'\Psi(1) = 0$. The long-run forecast of the cointegrated system shows that the cointegrated relationship holds, although there might exist some deviations from the equilibrium status in the short-run. The covariance matrix of the predict error $\mathbf{e}_{t+l|t} = \mathbf{y}_{t+l} - \mathbf{y}_{t+l|t}$ is

$$\Sigma(l) = \sum_{i=1}^l [(\sum_{j=0}^{l-i} \Psi_j) \Sigma (\sum_{j=0}^{l-i} \Psi_j)']$$

When the linear process is represented as a VECM(p) model, you can obtain

$$\Delta \mathbf{y}_t = \Pi \mathbf{y}_{t-1} + \sum_{j=1}^{p-1} \Phi_j^* \Delta \mathbf{y}_{t-j} + \boldsymbol{\delta} + \boldsymbol{\epsilon}_t$$

The transition equation is defined as

$$\mathbf{z}_t = F \mathbf{z}_{t-1} + \mathbf{e}_t$$

where $\mathbf{z}_t = (\mathbf{y}'_{t-1}, \Delta \mathbf{y}'_t, \Delta \mathbf{y}'_{t-1}, \dots, \Delta \mathbf{y}'_{t-p+2})'$ is a state vector and the transition matrix is

$$F = \begin{bmatrix} I_k & I_k & 0 & \cdots & 0 \\ \Pi & (\Pi + \Phi_1^*) & \Phi_2^* & \cdots & \Phi_{p-1}^* \\ 0 & I_k & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & I_k & 0 \end{bmatrix}$$

where 0 is a $k \times k$ zero matrix. The observation equation can be written

$$\mathbf{y}_t = \boldsymbol{\delta}t + H\mathbf{z}_t$$

where $H = [I_k, I_k, 0, \dots, 0]$.

The l -step-ahead forecast is computed as

$$\mathbf{y}_{t+l|t} = \boldsymbol{\delta}(t+l) + HF^l \mathbf{z}_t$$

Cointegration with Exogenous Variables

The error correction model with exogenous variables can be written as follows:

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha}\boldsymbol{\beta}'\mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + AD_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

The following statements demonstrate how to fit VECMX(p, s), where $p = 2$ and $s = 1$ from the P=2 and XLAG=1 options:

```
proc varmax data=simul3;
  model y1 y2 = x1 / p=2 xlag=1 ecm=(rank=1);
run;
```

The following statements demonstrate how to BVECMX(2,1):

```
proc varmax data=simul3;
  model y1 y2 = x1 / p=2 xlag=1 ecm=(rank=1)
  prior=(lambda=0.9 theta=0.1);
run;
```

I(2) Model

The VARX(p, s) model can be written in the error correction form:

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha}\boldsymbol{\beta}'\mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + AD_t + \sum_{i=0}^s \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

Let $\Phi^* = I_k - \sum_{i=1}^{p-1} \Phi_i^*$.

If α and β have full-rank r , and $\text{rank}(\alpha'_\perp \Phi^* \beta_\perp) = k - r$, then y_t is an $I(1)$ process.

If the condition $\text{rank}(\alpha'_\perp \Phi^* \beta_\perp) = k - r$ fails and $\alpha'_\perp \Phi^* \beta_\perp$ has reduced-rank $\alpha'_\perp \Phi^* \beta_\perp = \xi \eta'$ where ξ and η are $(k - r) \times s$ matrices with $s \leq k - r$, then α_\perp and β_\perp are defined as $k \times (k - r)$ matrices of full rank such that $\alpha' \alpha_\perp = 0$ and $\beta' \beta_\perp = 0$.

If ξ and η have full-rank s , then the process y_t is $I(2)$, which has the implication of $I(2)$ model for the moving-average representation.

$$y_t = B_0 + B_1 t + C_2 \sum_{j=1}^t \sum_{i=1}^j \epsilon_i + C_1 \sum_{i=1}^t \epsilon_i + C_0(B) \epsilon_t$$

The matrices C_1 , C_2 , and $C_0(B)$ are determined by the cointegration properties of the process, and B_0 and B_1 are determined by the initial values. For details, see Johansen (1995a).

The implication of the $I(2)$ model for the autoregressive representation is given by

$$\Delta^2 y_t = \Pi y_{t-1} - \Phi^* \Delta y_{t-1} + \sum_{i=1}^{p-2} \Psi_i \Delta^2 y_{t-i} + A D_t + \sum_{i=0}^s \Theta_i^* x_{t-i} + \epsilon_t$$

where $\Psi_i = -\sum_{j=i+1}^{p-1} \Phi_j^*$ and $\Phi^* = I_k - \sum_{i=1}^{p-1} \Phi_i^*$.

Test for I(2)

The $I(2)$ cointegrated model is given by the following parameter restrictions:

$$H_{r,s}: \Pi = \alpha \beta' \text{ and } \alpha'_\perp \Phi^* \beta_\perp = \xi \eta'$$

where ξ and η are $(k - r) \times s$ matrices with $0 \leq s \leq k - r$. Let H_r^0 represent the $I(1)$ model where α and β have full-rank r , let $H_{r,s}^0$ represent the $I(2)$ model where ξ and η have full-rank s , and let $H_{r,s}$ represent the $I(2)$ model where ξ and η have rank $\leq s$. The following table shows the relation between the $I(1)$ models and the $I(2)$ models.

Table 32.2 Relation between the $I(1)$ and $I(2)$ Models

		$I(2)$				$I(1)$					
$r \setminus k - r - s$	k	$k-1$...	1							
0	H_{00}	\subset	H_{01}	\subset	...	\subset	$H_{0,k-1}$	\subset	H_{0k}	$=$	H_0^0
1			H_{10}	\subset	...	\subset	$H_{1,k-2}$	\subset	$H_{1,k-1}$	$=$	H_1^0
⋮							⋮		⋮		⋮
$k-1$							$H_{k-1,0}$	\subset	$H_{k-1,1}$	$=$	H_{k-1}^0

Johansen (1995a) proposed the two-step procedure to analyze the $I(2)$ model. In the first step, the values of (r, α, β) are estimated using the reduced rank regression analysis, performing the regression analysis $\Delta^2 \mathbf{y}_t, \Delta \mathbf{y}_{t-1}$, and \mathbf{y}_{t-1} on $\Delta^2 \mathbf{y}_{t-1}, \dots, \Delta^2 \mathbf{y}_{t-p+2}$, and D_t . This gives residuals R_{0t}, R_{1t} , and R_{2t} , and residual product moment matrices

$$M_{ij} = \frac{1}{T} \sum_{t=1}^T R_{it} R'_{jt} \text{ for } i, j = 0, 1, 2$$

Perform the reduced rank regression analysis $\Delta^2 \mathbf{y}_t$ on \mathbf{y}_{t-1} corrected for $\Delta \mathbf{y}_{t-1}, \Delta^2 \mathbf{y}_{t-1}, \dots, \Delta^2 \mathbf{y}_{t-p+2}$, and D_t , and solve the eigenvalue problem of the equation

$$|\lambda M_{22.1} - M_{20.1} M_{00.1}^{-1} M_{02.1}| = 0$$

where $M_{ij.1} = M_{ij} - M_{i1} M_{11}^{-1} M_{1j}$ for $i, j = 0, 2$.

In the second step, if (r, α, β) are known, the values of (s, ξ, η) are determined using the reduced rank regression analysis, regressing $\hat{\alpha}'_{\perp} \Delta^2 \mathbf{y}_t$ on $\hat{\beta}'_{\perp} \Delta \mathbf{y}_{t-1}$ corrected for $\Delta^2 \mathbf{y}_{t-1}, \dots, \Delta^2 \mathbf{y}_{t-p+2}, D_t$, and $\hat{\beta}'_{\perp} \Delta \mathbf{y}_{t-1}$.

The reduced rank regression analysis reduces to the solution of an eigenvalue problem for the equation

$$|\rho M_{\beta_{\perp} \beta_{\perp} \cdot \beta} - M_{\beta_{\perp} \alpha_{\perp} \cdot \beta} M_{\alpha_{\perp} \alpha_{\perp} \cdot \beta}^{-1} M_{\alpha_{\perp} \beta_{\perp} \cdot \beta}| = 0$$

where

$$\begin{aligned} M_{\beta_{\perp} \beta_{\perp} \cdot \beta} &= \beta'_{\perp} (M_{11} - M_{11} \beta (\beta' M_{11} \beta)^{-1} \beta' M_{11}) \beta_{\perp} \\ M'_{\beta_{\perp} \alpha_{\perp} \cdot \beta} &= M_{\alpha_{\perp} \beta_{\perp} \cdot \beta} = \bar{\alpha}'_{\perp} (M_{01} - M_{01} \beta (\beta' M_{11} \beta)^{-1} \beta' M_{11}) \beta_{\perp} \\ M_{\alpha_{\perp} \alpha_{\perp} \cdot \beta} &= \bar{\alpha}'_{\perp} (M_{00} - M_{01} \beta (\beta' M_{11} \beta)^{-1} \beta' M_{10}) \bar{\alpha}_{\perp} \end{aligned}$$

where $\bar{\alpha} = \alpha (\alpha' \alpha)^{-1}$.

The solution gives eigenvalues $1 > \rho_1 > \dots > \rho_s > 0$ and eigenvectors (v_1, \dots, v_s) . Then, the ML estimators are

$$\begin{aligned} \hat{\eta} &= (v_1, \dots, v_s) \\ \hat{\xi} &= M_{\alpha_{\perp} \beta_{\perp} \cdot \beta} \hat{\eta} \end{aligned}$$

The likelihood ratio test for the reduced rank model $H_{r,s}$ with rank $\leq s$ in the model $H_{r,k-r} = H_r^0$ is given by

$$Q_{r,s} = -T \sum_{i=s+1}^{k-r} \log(1 - \rho_i), \quad s = 0, \dots, k - r - 1$$

The following statements compute the rank test to test for cointegrated order 2:

```
proc varmax data=simul2;
  model y1 y2 / p=2 cointtest=(johansen=(iorder=2));
run;
```

The last two columns in Figure 32.60 explain the cointegration rank test with integrated order 1. The results indicate that there is the cointegrated relationship with the cointegration rank 1 with respect to the 0.05 significance level because the test statistic of 0.5552 is smaller than the critical value of 3.84. Now, look at the row associated with $r = 1$. Compare the test statistic value, 211.84512, to the critical value, 3.84, for the cointegrated order 2. There is no evidence that the series are integrated order 2 at the 0.05 significance level.

5% CV I(2)	15.34000	3.84000		

Multivariate GARCH Modeling

Stochastic volatility modeling is important in many areas, particularly in finance. To study the volatility of time series, GARCH models are widely used because they provide a good approach to conditional variance modeling.

BEKK Representation

Engle and Kroner (1995) propose a general multivariate GARCH model and call it a *BEKK* representation. Let $\mathcal{F}(t-1)$ be the sigma field generated by the past values of ϵ_t , and let H_t be the conditional covariance matrix of the k -dimensional random vector ϵ_t . Let H_t be measurable with respect to $\mathcal{F}(t-1)$; then the multivariate GARCH model can be written as

$$\epsilon_t | \mathcal{F}(t-1) \sim N(0, H_t)$$

$$H_t = C + \sum_{i=1}^q A_i' \epsilon_{t-i} \epsilon_{t-i}' A_i + \sum_{i=1}^p G_i' H_{t-i} G_i$$

where C , A_i and G_i are $k \times k$ parameter matrices.

Consider a bivariate GARCH(1,1) model as follows:

$$H_t = \begin{bmatrix} c_{11} & c_{12} \\ c_{12} & c_{22} \end{bmatrix} + \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}' \begin{bmatrix} \epsilon_{1,t-1}^2 & \epsilon_{1,t-1}\epsilon_{2,t-1} \\ \epsilon_{2,t-1}\epsilon_{1,t-1} & \epsilon_{2,t-1}^2 \end{bmatrix} \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \\ + \begin{bmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{bmatrix}' H_{t-1} \begin{bmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{bmatrix}$$

or, representing the univariate model,

$$h_{11,t} = c_{11} + a_{11}^2 \epsilon_{1,t-1}^2 + 2a_{11}a_{21}\epsilon_{1,t-1}\epsilon_{2,t-1} + a_{21}^2 \epsilon_{2,t-1}^2 \\ + g_{11}^2 h_{11,t-1} + 2g_{11}g_{21}h_{12,t-1} + g_{21}^2 h_{22,t-1} \\ h_{12,t} = c_{12} + a_{11}a_{12}\epsilon_{1,t-1}^2 + (a_{21}a_{12} + a_{11}a_{22})\epsilon_{1,t-1}\epsilon_{2,t-1} + a_{21}a_{22}\epsilon_{2,t-1}^2 \\ + g_{11}g_{12}h_{11,t-1} + (g_{21}g_{12} + g_{11}g_{22})h_{12,t-1} + g_{21}g_{22}h_{22,t-1} \\ h_{22,t} = c_{22} + a_{12}^2 \epsilon_{1,t-1}^2 + 2a_{12}a_{22}\epsilon_{1,t-1}\epsilon_{2,t-1} + a_{22}^2 \epsilon_{2,t-1}^2 \\ + g_{12}^2 h_{11,t-1} + 2g_{12}g_{22}h_{12,t-1} + g_{22}^2 h_{22,t-1}$$

For the *BEKK* representation of the bivariate GARCH(1,1) model, the SAS statements are:

```
model y1 y2;
garch q=1 p=1 form=bekk;
```

CCC Representation

Bollerslev (1990) propose a multivariate GARCH model with time-varying conditional variances and covariances but constant conditional correlations.

The conditional covariance matrix H_t consists of

$$H_t = D_t \Gamma D_t$$

where D_t is a $k \times k$ stochastic diagonal matrix with element σ_{it} and Γ is a $k \times k$ time-invariant matrix with the typical element ρ_{ij} .

The elements of H_t are

$$h_{ii,t} = c_i + \sum_{l=1}^q a_{ii,l} \epsilon_{i,t-l}^2 + \sum_{l=1}^p g_{ii,l} h_{ii,t-l} \quad i, j = 1, \dots, k \\ h_{ij,t} = \rho_{ij} (h_{ii,t} h_{jj,t})^{1/2} \quad i \neq j$$

Estimation of GARCH Model

The log-likelihood function of the multivariate GARCH model is written without a constant term

$$\ell = -\frac{1}{2} \sum_{t=1}^T [\log |H_t| + \boldsymbol{\epsilon}_t' H_t^{-1} \boldsymbol{\epsilon}_t]$$

The log-likelihood function is maximized by an iterative numerical method such as quasi-Newton optimization. The starting values for the regression parameters are obtained from the least squares estimates. The covariance of $\boldsymbol{\epsilon}_t$ is used as the starting values for the GARCH constant parameters, and the starting value used for the other GARCH parameters is either 10^{-6} or 10^{-3} depending on the GARCH models representation. For the identification of the parameters of a *BEKK* representation GARCH model, the diagonal elements of the GARCH constant, the ARCH, and the GARCH parameters are restricted to be positive.

Covariance Stationarity

Define the multivariate GARCH process as

$$\mathbf{h}_t = \sum_{i=1}^{\infty} G(B)^{i-1} [\mathbf{c} + A(B)\boldsymbol{\eta}_t]$$

where $\mathbf{h}_t = \text{vec}(H_t)$, $\mathbf{c} = \text{vec}(C_0)$, and $\boldsymbol{\eta}_t = \text{vec}(\boldsymbol{\epsilon}_t \boldsymbol{\epsilon}_t')$. This representation is equivalent to a GARCH(p, q) model by the following algebra:

$$\begin{aligned} \mathbf{h}_t &= \mathbf{c} + A(B)\boldsymbol{\eta}_t + \sum_{i=2}^{\infty} G(B)^{i-1} [\mathbf{c} + A(B)\boldsymbol{\eta}_t] \\ &= \mathbf{c} + A(B)\boldsymbol{\eta}_t + G(B) \sum_{i=1}^{\infty} G(B)^{i-1} [\mathbf{c} + A(B)\boldsymbol{\eta}_t] \\ &= \mathbf{c} + A(B)\boldsymbol{\eta}_t + G(B)\mathbf{h}_t \end{aligned}$$

Defining $A(B) = \sum_{i=1}^q (A_i \otimes A_i)' B^i$ and $G(B) = \sum_{i=1}^p (G_i \otimes G_i)' B^i$ gives a *BEKK* representation.

The necessary and sufficient conditions for covariance stationarity of the multivariate GARCH process is that all the eigenvalues of $A(1) + G(1)$ are less than one in modulus.

An Example of a VAR(1)–ARCH(1) Model

The following DATA step simulates a bivariate vector time series to provide test data for the multivariate GARCH model:

```
data garch;
  retain seed 16587;
  esq1 = 0; esq2 = 0;
  ly1 = 0; ly2 = 0;
  do i = 1 to 1000;
    ht = 6.25 + 0.5*esq1;
    call rannor(seed, ehat);
    e1 = sqrt(ht)*ehat;
    ht = 1.25 + 0.7*esq2;
    call rannor(seed, ehat);
    e2 = sqrt(ht)*ehat;
    y1 = 2 + 1.2*ly1 - 0.5*ly2 + e1;
    y2 = 4 + 0.6*ly1 + 0.3*ly2 + e2;
    if i>500 then output;
    esq1 = e1*e1; esq2 = e2*e2;
    ly1 = y1; ly2 = y2;
  end;
  keep y1 y2;
run;
```

The following statements fit a VAR(1)–ARCH(1) model to the data. For a VAR-ARCH model, you specify the order of the autoregressive model with the P=1 option in the MODEL statement and the Q=1 option in the GARCH statement. In order to produce the initial and final values of parameters, the TECH=QN option is specified in the NLOPTIONS statement.

```
proc varmax data=garch;
  model y1 y2 / p=1
    print=(roots estimates diagnose);
  garch q=1;
  nloptions tech=qn;
run;
```

Figure 32.61 through Figure 32.65 show the details of this example. Figure 32.61 shows the initial values of parameters.

Output Data Sets

The VARMAX procedure can create the OUT=, OUTEST=, OUTHT=, and OUTSTAT= data sets. In general, if processing fails, the output is not recorded or is set to missing in the relevant output data set, and appropriate error and/or warning messages are recorded in the log.

OUT= Data Set

The OUT= data set contains the forecast values produced by the OUTPUT statement. The following output variables can be created:

- the BY variables
- the ID variable
- the MODEL statement dependent (endogenous) variables. These variables contain the actual values from the input data set.
- FOR_i , numeric variables that contain the forecasts. The FOR_i variables contain the forecasts for the i th endogenous variable in the MODEL statement list. Forecasts are one-step-ahead predictions until the end of the data or until the observation specified by the BACK= option. Multistep forecasts can be computed after that point based on the LEAD= option.
- RES_i , numeric variables that contain the residual for the forecast of the i th endogenous variable in the MODEL statement list. For multistep forecast observations, the actual values are missing and the RES_i variables contain missing values.
- STD_i , numeric variables that contain the standard deviation for the forecast of the i th endogenous variable in the MODEL statement list. The values of the STD_i variables can be used to construct univariate confidence limits for the corresponding forecasts.
- LCI_i , numeric variables that contain the lower confidence limits for the corresponding forecasts of the i th endogenous variable in the MODEL statement list.
- UCI_i , numeric variables that contain the upper confidence limits for the corresponding forecasts of the i th endogenous variable in the MODEL statement list.

The OUT= data set contains the values shown in Table 32.3 and Table 32.4 for a bivariate case.

Table 32.3 OUT= Data Set

Obs	ID variable	y1	FOR1	RES1	STD1	LCI1	UCI1

OUTEST= Data Set

The OUTEST= data set contains estimation results of the fitted model produced by the VARMAX statement. The following output variables can be created:

- the BY variables
- NAME, a character variable that contains the name of endogenous (dependent) variables or the name of the parameters for the covariance of the matrix of the parameter estimates if the OUTCOV option is specified
- TYPE, a character variable that contains the value EST for parameter estimates, the value STD for standard error of parameter estimates, and the value COV for the covariance of the matrix of the parameter estimates if the OUTCOV option is specified

- CONST, a numeric variable that contains the estimates of constant parameters and their standard errors
- SEASON_ *i*, a numeric variable that contains the estimates of seasonal dummy parameters and their standard errors, where $i = 1, \dots, (nseason - 1)$, and *nseason* is based on the NSEASON= option
- LTREND, a numeric variable that contains the estimates of linear trend parameters and their standard errors
- QTREND, a numeric variable that contains the estimates of quadratic trend parameters and their standard errors
- XLL_ *i*, numeric variables that contain the estimates of exogenous parameters and their standard errors, where *l* is the lag *l*th coefficient matrix and $i = 1, \dots, r$, where *r* is the number of exogenous variables
- ARl_ *i*, numeric variables that contain the estimates of autoregressive parameters and their standard errors, where *l* is the lag *l*th coefficient matrix and $i = 1, \dots, k$, where *k* is the number of endogenous variables
- MAl_ *i*, numeric variables that contain the estimates of moving-average parameters and their standard errors, where *l* is the lag *l*th coefficient matrix and $i = 1, \dots, k$, where *k* is the number of endogenous variables
- ACHl_ *i* are numeric variables that contain the estimates of the ARCH parameters of the covariance matrix and their standard errors, where *l* is the lag *l*th coefficient matrix and $i = 1, \dots, k$ for BEKK and CCC representations, where *k* is the number of endogenous variables.
- GCHl_ *i* are numeric variables that contain the estimates of the GARCH parameters of the covariance matrix and their standard errors, where *l* is the lag *l*th coefficient matrix and $i = 1, \dots, k$ for BEKK and CCC representations, where *k* is the number of endogenous variables.
- GCHC_ *i* are numeric variables that contain the estimates of the constant parameters of the covariance matrix and their standard errors, where $i = 1, \dots, k$ for BEKK representation, *k* is the number of endogenous variables, and $i = 1$ for CCC representation.
- CCC_ *i* are numeric variables that contain the estimates of the conditional constant correlation parameters for CCC representation where $i = 2, \dots, k$.

The OUTEST= data set contains the values shown Table 32.5 for a bivariate case.

Table 32.5 OUTEST= Data Set

Obs	NAME	TYPE	CONST	AR1_1	AR1_2	AR2_1	AR2_2
1	y1	EST	δ_1	$\phi_{1,11}$	$\phi_{1,12}$	$\phi_{2,11}$	$\phi_{2,12}$

OUTHT= Data Set

The OUTHT= data set contains prediction of the fitted GARCH model produced by the GARCH statement. The following output variables can be created.

- the BY variables
- H_{i_j} , numeric variables that contain the prediction of covariance, where $1 \leq i < j \leq k$, where k is the number of dependent variables

The OUTHT= data set contains the values shown in Table 32.6 for a bivariate case.

Table 32.6 OUTHT= Data Set

OUTSTAT= Data Set

The OUTSTAT= data set contains estimation results of the fitted model produced by the VARMAX statement. The following output variables can be created. The subindex i is $1, \dots, k$, where k is the number of endogenous variables.

- the BY variables
- NAME, a character variable that contains the name of endogenous (dependent) variables
- SIGMA_ i , numeric variables that contain the estimate of the innovation covariance matrix
- AICC, a numeric variable that contains the corrected Akaike's information criterion value
- HQC, a numeric variable that contains the Hannan-Quinn's information criterion value
- AIC, a numeric variable that contains the Akaike's information criterion value
- SBC, a numeric variable that contains the Schwarz Bayesian's information criterion value
- FPEC, a numeric variable that contains the final prediction error criterion value
- FValue, a numeric variable that contains the F statistics
- PValue, a numeric variable that contains p -value for the F statistics

If the JOHANSEN= option is specified, the following items are added:

- Eigenvalue, a numeric variable that contains eigenvalues for the cointegration rank test of integrated order 1

- RestrictedEigenvalue, a numeric variable that contains eigenvalues for the cointegration rank test of integrated order 1 when the NOINT option is not specified
- Beta_1, numeric variables that contain long-run effect parameter estimates, β
- Alpha_1, numeric variables that contain adjustment parameter estimates, α

If the JOHANSEN=(IORDER=2) option is specified, the following items are added:

- EValueI2_1, numeric variables that contain eigenvalues for the cointegration rank test of integrated order 2
- EValueI1, a numeric variable that contains eigenvalues for the cointegration rank test of integrated order 1
- Eta_1, numeric variables that contain the parameter estimates in integrated order 2, η
- Xi_1, numeric variables that contain the parameter estimates in integrated order 2, ξ

The OUTSTAT= data set contains the values shown [Table 32.7](#) for a bivariate case.

Table 32.7 OUTSTAT= Data Set

Printed Output

The default printed output produced by the VARMAX procedure is described in the following list:

- descriptive statistics, which include the number of observations used, the names of the variables, their means and standard deviations (STD), their minimums and maximums, the differencing operations used, and the labels of the variables
- a type of model to fit the data and an estimation method
- a table of parameter estimates that shows the following for each parameter: the variable name for the left-hand side of equation, the parameter name, the parameter estimate, the approximate standard error, t value, the approximate probability ($Pr > |t|$), and the variable name for the right-hand side of equations in terms of each parameter
- the innovation covariance matrix
- the information criteria

If PRINT=ESTIMATES is specified, the VARMAX procedure prints the following list with the default printed output:

- the estimates of the constant vector (or seasonal constant matrix), the trend vector, the coefficient matrices of the distributed lags, the AR coefficient matrices, and the MA coefficient matrices
- the ALPHA and BETA parameter estimates for the error correction model
- the schematic representation of parameter estimates

If PRINT=DIAGNOSE is specified, the VARMAX procedure prints the following list with the default printed output:

- the cross-covariance and cross-correlation matrices of the residuals
- the tables of test statistics for the hypothesis that the residuals of the model are white noise:
 - Durbin-Watson (DW) statistics
 - F test for autoregressive conditional heteroscedastic (ARCH) disturbances
 - F test for AR disturbance
 - Jarque-Bera normality test
 - Portmanteau test

ODS Table Names

The VARMAX procedure assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table:

Table 32.8 ODS Tables Produced in the VARMAX Procedure

ODS Table Name	Description	Option

ODS Graphics

This section describes the use of ODS for creating statistical graphs with the VARMAX procedure.

To request these graphs, you must specify the ODS GRAPHICS ON statement.

When ODS GRAPHICS are in effect, the VARMAX procedure produces a variety of plots for each dependent variable.

The plots available are as follows:

- The procedure displays the following plots for each dependent variable in the MODEL statement with the PLOT= option in the VARMAX statement:
 - impulse response function
 - impulse response of the transfer function
 - time series and predicted series
 - prediction errors
 - distribution of the prediction errors
 - normal quantile of the prediction errors
 - ACF of the prediction errors
 - PACF of the prediction errors
 - IACF of the prediction errors
 - log scaled white noise test of the prediction errors
- The procedure displays forecast plots for each dependent variable in the OUTPUT statement with the PLOT= option in the VARMAX statement.

ODS Graph Names

The VARMAX procedure assigns a name to each graph it creates by using ODS. You can use these names to reference the graphs when using ODS. The names are listed in [Table 32.9](#).

Table 32.9 ODS Graphics Produced in the VARMAX Procedure

ODS Table Name	Plot Description	Statement

Computational Issues

Computational Method

The VARMAX procedure uses numerous linear algebra routines and frequently uses the sweep operator (Goodnight 1979) and the Cholesky root (Golub and Van Loan 1983).

In addition, the VARMAX procedure uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks for the maximum likelihood estimation. The optimization requires intensive computation.

Convergence Problems

For some data sets, the computation algorithm can fail to converge. Nonconvergence can result from a number of causes, including flat or ridged likelihood surfaces and ill-conditioned data.

If you experience convergence problems, the following points might be helpful:

- Data that contain extreme values can affect results in PROC VARMAX. Rescaling the data can improve stability.
- Changing the TECH=, MAXITER=, and MAXFUNC= options in the NLOPTIONS statement can improve the stability of the optimization process.
- Specifying a different model that might fit the data more closely and might improve convergence.

Memory

Let T be the length of each series, k be the number of dependent variables, p be the order of autoregressive terms, and q be the order of moving-average terms. The number of parameters to estimate for a VARMA(p, q) model is

$$k + (p + q)k^2 + k * (k + 1)/2$$

As k increases, the number of parameters to estimate increases very quickly. Furthermore the memory requirement for VARMA(p, q) quadratically increases as k and T increase.

For a VARMAX(p, q, s) model and GARCH-type multivariate conditional heteroscedasticity models, the number of parameters to estimate and the memory requirements are considerable.

Computing Time

PROC VARMAX is computationally intensive, and execution times can be long. Extensive CPU time is often required to compute the maximum likelihood estimates.

Examples: VARMAX Procedure

Example 32.1: Analysis of U.S. Economic Variables

Consider the following four-dimensional system of U.S. economic variables. Quarterly data for the years 1954 to 1987 are used (Lütkepohl 1993, Table E.3.).

```

title 'Analysis of U.S. Economic Variables';
data us_money;
  date=intnx( 'qtr', '01jan54'd, _n_-1 );
  format date yyq. ;
  input y1 y2 y3 y4 @@;
  y1=log(y1);
  y2=log(y2);
  label y1='log(real money stock M1)'
        y2='log(GNP in bil. of 1982 dollars)'
        y3='Discount rate on 91-day T-bills'
        y4='Yield on 20-year Treasury bonds';
datalines;
450.9 1406.8 0.010800000 0.026133333
453.0 1401.2 0.0081333333 0.025233333

... more lines ...

```

The following statements plot the series and proceed with the VARMAX procedure.

```
proc timeseries data=us_money vectorplot=series;
  id date interval=qtr;
  var y1 y2;
run;
```

Output 32.1.1 shows the plot of the variables y1 and y2.

Output 32.1.1 Plot of Data

The following statements plot the variables y3 and y4.

```
proc timeseries data=us_money vectorplot=series;
  id date interval=qtr;
  var y3 y4;
run;
```

Output 32.1.2 shows the plot of the variables y3 and y4.

Output 32.1.2 Plot of Data

```
proc varmax data=us_money;
  id date interval=qtr;
  model y1-y4 / p=2 lagmax=6 dfest
    print=(iarr(3) estimates diagnose)
    cointtest=(johansen=(iorder=2))
    ecm=(rank=1 normalize=y1);
  cointeg rank=1 normalize=y1 exogeneity;
run;
```

This example performs the Dickey-Fuller test for stationarity, the Johansen cointegrated test integrated order 2, and the exogeneity test. The VECM(2) is fit to the data. From the outputs shown in [Output 32.1.5](#), you can see that the series has unit roots and is cointegrated in rank 1 with integrated order 1. The fitted VECM(2) is given as

$$\Delta \mathbf{y}_t = \begin{pmatrix} 0.0408 \\ 0.0860 \\ 0.0052 \\ -0.0144 \end{pmatrix} + \begin{pmatrix} -0.0140 & 0.0065 & -0.2026 & 0.1306 \\ -0.0281 & 0.0131 & -0.4080 & 0.2630 \\ -0.0022 & 0.0010 & -0.0312 & 0.0201 \\ 0.0051 & -0.0024 & 0.0741 & -0.0477 \end{pmatrix} \mathbf{y}_{t-1} + \begin{pmatrix} 0.3460 & 0.0913 & -0.3535 & -0.9690 \\ 0.0994 & 0.0379 & 0.2390 & 0.2866 \\ 0.1812 & 0.0786 & 0.0223 & 0.4051 \\ 0.0322 & 0.0496 & -0.0329 & 0.1857 \end{pmatrix} \Delta \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

The Δ prefixed to a variable name implies differencing.

Output 32.1.3 through Output 32.1.14 show the details. Output 32.1.3 shows the descriptive statistics.

Output 32.1.3 Descriptive Statistics

Analysis of U.S. Economic Variables						
The VARMAX Procedure

The Johansen cointegration rank test shows whether the series is integrated order either 1 or 2 as shown in [Output 32.1.5](#). The last two columns in [Output 32.1.5](#) explain the cointegration rank test with integrated order 1. The results indicate that there is the cointegrated relationship with the cointegration rank 1 with respect to the 0.05 significance level because the test statistic of 20.6542 is smaller than the critical value of 29.38. Now, look at the row associated with $r = 1$. Compare the test statistic value and critical value pairs such as (219.62395, 29.38), (89.21508, 15.34), and (27.32609, 3.84). There is no evidence that the series are integrated order 2 at the 0.05 significance level.

Output 32.1.5 Cointegration Rank Test

Cointegration Rank Test for I(2)					
r\k-r-s	4	3	2	1	Trace of I(1)

y2	1	12.54	0.0004	
y3	1	0.09	0.7695	
y4	1	1.81	0.1786	

Example 32.2: Analysis of German Economic Variables

This example considers a three-dimensional VAR(2) model. The model contains the logarithms of a quarterly, seasonally adjusted West German fixed investment, disposable income, and consumption expenditures. The data used are in Lütkepohl (1993, Table E.1).

```

title 'Analysis of German Economic Variables';
data west;
  date = intnx( 'qtr', '01jan60'd, _n_-1 );
  format date yyq. ;
  input y1 y2 y3 @@;
  y1 = log(y1);
  y2 = log(y2);
  y3 = log(y3);
  label y1 = 'logarithm of investment'
        y2 = 'logarithm of income'
        y3 = 'logarithm of consumption';
datalines;
180 451 415 179 465 421 185 485 434 192 493 448

... more lines ...

data use;
  set west;
  where date < '01jan79'd;
  keep date y1 y2 y3;
run;

proc varmax data=use;
  id date interval=qtr;
  model y1-y3 / p=2 dify=(1)
          print=(decompose(6) impulse=(stderr) estimates diagnose)
          printform=both lagmax=3;
  causal group1=(y1) group2=(y2 y3);
  output lead=5;
run;

```

First, the differenced data is modeled as a VAR(2) with the following result:

$$\begin{aligned}
 \Delta \mathbf{y}_t = & \begin{pmatrix} -0.01672 \\ 0.01577 \\ 0.01293 \end{pmatrix} + \begin{pmatrix} -0.31963 & 0.14599 & 0.96122 \\ 0.04393 & -0.15273 & 0.28850 \\ -0.00242 & 0.22481 & -0.26397 \end{pmatrix} \Delta \mathbf{y}_{t-1} \\
 & + \begin{pmatrix} -0.16055 & 0.11460 & 0.93439 \\ 0.05003 & 0.01917 & -0.01020 \\ 0.03388 & 0.35491 & -0.02223 \end{pmatrix} \Delta \mathbf{y}_{t-2} + \boldsymbol{\epsilon}_t
 \end{aligned}$$

The parameter estimates AR1_1_2, AR1_1_3, AR2_1_2, and AR2_1_3 are insignificant, and the VARX model is fitted in the next step.

The detailed output is shown in [Output 32.2.1](#) through [Output 32.2.8](#).

[Output 32.2.1](#) shows the descriptive statistics.

Output 32.2.1 Descriptive Statistics

Output 32.2.9 shows that you cannot reject Granger noncausality from (y2, y3) to y1 using the 0.05 significance level.

Output 32.2.9 Granger Causality Tests

Granger-Causality Wald Test			
Test	DF	Chi-Square	Pr > ChiSq
1	4	6.37	0.1734
Test 1: Group 1 Variables: y1			
Group 2 Variables: y2 y3			

The following SAS statements show that the variable y1 is the exogenous variable and fit the VARX(2,1) model to the data.

```
proc varmax data=use;
  id date interval=qtr;
  model y2 y3 = y1 / p=2 dify=(1) difx=(1) xlag=1 lagmax=3
    print=(estimates diagnose);
run;
```

The fitted VARX(2,1) model is written as

$$\begin{pmatrix} \Delta y_{2t} \\ \Delta y_{3t} \end{pmatrix} = \begin{pmatrix} 0.01542 \\ 0.01319 \end{pmatrix} + \begin{pmatrix} 0.02520 \\ 0.05130 \end{pmatrix} \Delta y_{1t} + \begin{pmatrix} 0.03870 \\ 0.00363 \end{pmatrix} \Delta y_{1,t-1} \\ + \begin{pmatrix} -0.12258 & 0.25811 \\ 0.24367 & -0.31809 \end{pmatrix} \begin{pmatrix} \Delta y_{2,t-1} \\ \Delta y_{3,t-1} \end{pmatrix} \\ + \begin{pmatrix} 0.01651 & 0.03498 \\ 0.34921 & -0.01664 \end{pmatrix} \begin{pmatrix} \Delta y_{2,t-2} \\ \Delta y_{3,t-2} \end{pmatrix} + \begin{pmatrix} \epsilon_{1t} \\ \epsilon_{2t} \end{pmatrix}$$

The detailed output is shown in [Output 32.2.10](#) through [Output 32.2.13](#).

Output 32.2.10 shows the parameter estimates in terms of the constant, the current and the lag one coefficients of the exogenous variable, and the lag two coefficients of the dependent variables.

Output 32.2.10 Parameter Estimates

```

Example 32.4: Illustration of ODS Graphics

This example illustrates the use of ODS Graphics. The graphical displays are requested by specifying the ODS GRAPHICS ON statement. For information about the graphics available in the VARMAX procedure, see the section “ODS Graphics” on page 2191.

The following statements use the SASHELP.WORKERS data set to study the time series of electrical workers and its interaction with the series of masonry workers. The series and predict plots, the residual plot, and the forecast plot are created in [Output 32.4.1](#) through [Output 32.4.3](#). These are a selection of the plots created by the VARMAX procedure.

```

title "Illustration of ODS Graphics";
proc varmax data=sashelp.workers plot(unpack)=(residual model forecasts);
  id date interval=month;
  model electric masonry / dify=(1,12) noint p=1;
  output lead=12;
run;

```

Output 32.4.1 Series and Predicted Series Plots

Output 32.4.2 Residual Plot

Output 32.4.3 Series and Forecast Plots

Overview: X11 Procedure

The X11 procedure, an adaptation of the U.S. Bureau of the Census X-11 Seasonal Adjustment program, seasonally adjusts monthly or quarterly time series. The procedure makes additive or multiplicative adjustments and creates an output data set containing the adjusted time series and intermediate calculations.

The X11 procedure also provides the X-11-ARIMA method developed by Statistics Canada. This method fits an ARIMA model to the original series, then uses the model forecast to extend the original series. This extended series is then seasonally adjusted by the standard X-11 seasonal adjustment method. The extension of the series improves the estimation of the seasonal factors and reduces revisions to the seasonally adjusted series as new data become available.

The X11 procedure incorporates sliding spans analysis. This type of analysis provides a diagnostic for determining the suitability of seasonal adjustment for an economic series.

Seasonal adjustment of a series is based on the assumption that seasonal fluctuations can be measured in the original series, O_t , $t = 1, \dots, n$, and separated from trend cycle, trading-day, and irregular fluctuations. The seasonal component of this time series, S_t , is defined as the intrayear variation that is repeated constantly or in an evolving fashion from year to year. The trend cycle component, C_t , includes variation due to the long-term trend, the business cycle, and other long-term cyclical factors. The trading-day component, D_t , is the variation that can be attributed to the composition of the calendar. The irregular component, I_t , is the residual variation. Many economic time series are related in a multiplicative fashion ($O_t = S_t C_t D_t I_t$). A seasonally adjusted time series, $C_t I_t$, consists of only the trend cycle and irregular components.

Getting Started: X11 Procedure

The most common use of the X11 procedure is to produce a seasonally adjusted series. Eliminating the seasonal component from an economic series facilitates comparison among consecutive months or quarters. A plot of the seasonally adjusted series is often more informative about trends or location in a business cycle than a plot of the unadjusted series.

The following example shows how to use PROC X11 to produce a seasonally adjusted series, $C_t I_t$, from an original series $O_t = S_t C_t D_t I_t$.

In the multiplicative model, the trend cycle component C_t keeps the same scale as the original series O_t , while S_t , D_t , and I_t vary around 1.0. In all printed tables and in the output data set, these latter components are expressed as percentages, and thus will vary around 100.0 (in the additive case, they vary around 0.0).

The naming convention used in PROC X11 for the tables follows the original U.S. Bureau of the Census X-11 Seasonal Adjustment program specification (Shiskin, Young, and Musgrave 1967). Also, see the section “Printed Output” on page 2268. This convention is outlined in Figure 33.1.

The tables corresponding to parts A – C are intermediate calculations. The final estimates of the individual components are found in the D tables: table D10 contains the final seasonal factors, table D12 contains the final trend cycle, and table D13 contains the final irregular series. If you are primarily interested in seasonally adjusting a series without consideration of intermediate calculations or diagnostics, you only need to look at table D11, the final seasonally adjusted series.

For further details about the X-11-ARIMA tables, see Ladiray and Quenneville (2001).

Basic Seasonal Adjustment

Suppose you have monthly retail sales data starting in September 1978 in a SAS data set named SALES. At this point you do not suspect that any calendar effects are present, and there are no prior adjustments that need to be made to the data.

In this simplest case, you need only specify the DATE= variable in the MONTHLY statement, which associates a SAS date value to each observation. To see the results of the seasonal adjustment, you must request table D11, the final seasonally adjusted series, in a TABLES statement.

```
data sales;
  input sales @@;
  date = intnx( 'month', '01sep1978'd, _n_-1 );
  format date monyy7.;
datalines;

  ... more lines ...

/*--- X-11 ARIMA ---*/
proc x11 data=sales;
  monthly date=date;
  var sales;
  tables d11;
run;
```

legendlabel="adjusted" ;
yaxis label='Original and Seasonally Adjusted Time Series';
run;

```

Figure 33.3 Plot of Original and Seasonally Adjusted Data

X-11-ARIMA

An inherent problem with the X-11 method is the revision of the seasonal factor estimates as new data become available. The X-11 method uses a set of centered moving averages to estimate the seasonal components. These moving averages apply symmetric weights to all observations except those at the beginning and end of the series, where asymmetric weights have to be applied. These asymmetric weights can cause poor estimates of the seasonal factors, which then can cause large revisions when new data become available.

While large revisions to seasonally adjusted values are not common, they can happen. When they do happen, it undermines the credibility of the X-11 seasonal adjustment method.

A method to address this problem was developed at Statistics Canada (Dagum 1980, 1982a). This method, known as X-11-ARIMA, applies an ARIMA model to the original data (after adjustments, if any) to forecast the series one or more years. This extended series is then seasonally adjusted, allowing symmetric weights to be applied to the end of the original data. This method was tested against a large number of Canadian economic series and was found to greatly reduce the amount of revisions as new data were added.

The X-11-ARIMA method is available in PROC X11 through the use of the ARIMA statement. The ARIMA statement extends the original series either with a user-specified ARIMA model or by an automatic selection process in which the best model from a set of five predefined ARIMA models is used.

The following example illustrates the use of the ARIMA statement. The ARIMA statement does not contain a user-specified model, so the best model is chosen by the automatic selection process. Forecasts from this best model are then used to extend the original series by one year. The following partial listing shows parameter estimates and model diagnostics for the ARIMA model chosen by the automatic selection process.

```
proc x11 data=sales;
  monthly date=date;
  var sales;
  arima;
run;
```

Figure 33.4 X-11-ARIMA Model Selection

Monthly Retail Sales Data (in \$1000)				
The X11 Procedure				
Seasonal Adjustment of - sales				
Conditional Least Squares Estimation				
Approx.				
Parameter	Estimate	Std Error	t Value	Lag
MU	0.0001728	0.0009596	0.18	0
MA1,1	0.3739984	0.0893427	4.19	1
MA1,2	0.0231478	0.0892154	0.26	2
MA2,1	0.5727914	0.0790835	7.24	12
Conditional Least Squares Estimation				
Variance Estimate =	0.0014313			
Std Error Estimate =	0.0378326			
AIC =	-482.2412		*	
SBC =	-470.7404		*	
Number of Residuals=	131			
* Does not include log determinant				

Figure 33.4 *continued*

Criteria Summary for Model 2: (0,1,2) (0,1,1) _s , Log Transform	
Box-Ljung Chi-square:	22.03 with 21 df Prob= 0.40
	(Criteria prob > 0.05)
Test for over-differencing: sum of MA parameters =	0.57
	(must be < 0.90)
MAPE - Last Three Years:	2.84 (Must be < 15.00 %)
- Last Year:	3.04
- Next to Last Year:	1.96
- Third from Last Year:	3.51

Table D11 (final seasonally adjusted series) is now constructed using symmetric weights on observations at the end of the actual data. This should result in better estimates of the seasonal factors and, thus, smaller revisions in Table D11 as more data become available.

Syntax: X11 Procedure

The X11 procedure uses the following statements:

```

PROC X11 options ;
  ARIMA options ;
  BY variables ;
  ID variables ;
  MACURVES option ;
  MONTHLY options ;
  OUTPUT OUT=dataset options ;
  PDWEIGHTS option ;
  QUARTERLY options ;
  SSPAN options ;
  TABLES tablenames ;
  VAR variables ;

```

Either the MONTHLY or QUARTERLY statement must be specified, depending on the type of time series data you have. The PDWEIGHTS and MACURVES statements can be used only with the MONTHLY statement. The TABLES statement controls the printing of tables, while the OUTPUT statement controls the creation of the OUT= data set.

Functional Summary

The statements and options controlling the X11 procedures are summarized in the following table.

Description	Statement	Option
Data Set Options		
specify input data set	PROC X11	DATA=
write the trading-day regression results to an output data set	PROC X11	OUTTDR=
write the stable seasonality test results to an output data set	PROC X11	OUTSTB=
write table values to an output data set	OUTPUT	OUT=
add extrapolated values to the output data set	PROC X11	OUTEX
add year ahead estimates to the output data set	PROC X11	YRAHEADOUT
write the sliding spans analysis results to an output data set	PROC X11	OUTSPAN=
Printing Control Options		
suppress all printed output	PROC X11	NOPRINT
suppress all printed ARIMA output	ARIMA	NOPRINT
print all ARIMA output	ARIMA	PRINTALL
print selected tables and charts	TABLES	
print selected groups of tables	MONTHLY	PRINTOUT=
	QUARTERLY	PRINTOUT=
print selected groups of charts	MONTHLY	CHARTS=

specify seasonal factor moving average length	MACURVES	
specify the extreme value limit for trading-day regression	MONTHLY	EXCLUDE=
specify the lower bound for extreme irregulars	MONTHLY QUARTERLY	FULLWEIGHT= FULLWEIGHT=
specify the upper bound for extreme irregulars	MONTHLY QUARTERLY	ZEROWEIGHT= ZEROWEIGHT=
include the length-of-month in trading-day regression	MONTHLY	LENGTH
specify trading-day regression action	MONTHLY	TDREGR=
compute summary measure only	MONTHLY QUARTERLY	SUMMARY SUMMARY
modify extreme irregulars prior to trend cycle estimation	MONTHLY QUARTERLY	TRENDADJ TRENDADJ
specify moving average length in trend cycle estimation	MONTHLY QUARTERLY	TRENDMA= TRENDMA=
specify weights for prior trading-day factors	PDWEIGHTS	

PROC X11 Statement

PROC X11 *options* ;

The following options can appear in the PROC X11 statement:

DATA= *SAS-data-set*

specifies the input SAS data set used. If it is omitted, the most recently created SAS data set is used.

OUTEXTRAP

adds the extra observations used in ARIMA processing to the output data set.

When ARIMA forecasting/backcasting is requested, extra observations are appended to the ends of the series, and the calculations are carried out on this extended series. The appended observations are not normally written to the OUT= data set. However, if OUTEXTRAP is specified, these extra observations are written to the output data set. If a DATE= variable is specified in the MONTHLY/QUARTERLY statement, the date variable is extrapolated to identify forecasts/backcasts. The OUTEXTRAP option can be abbreviated as OUTEX.

NOPRINT

suppresses any printed output. The NOPRINT option overrides any PRINTOUT=, CHARTS=, or TABLES statement and any output associated with the ARIMA statement.

OUTSPAN= *SAS-data-set*

specifies the output data set to store the sliding spans analysis results. Tables A1, C18, D10, and D11 for each span are written to this data set. See the section “[The OUTSPAN= Data Set](#)” on page 2265 for details.

OUTSTB= *SAS-data-set*

specifies the output data set to store the stable seasonality test results (table D8). All the information in the analysis of variance table associated with the stable seasonality test is contained in the variables written to this data set. See the section “[OUTSTB= Data Set](#)” on page 2265 for details.

OUTTDR= *SAS-data-set*

specifies the output data set to store the trading-day regression results (tables B15 and C15). All the information in the analysis of variance table associated with the trading-day regression is contained in the variables written to this data set. This option is valid only when TDREGR=PRINT, TEST, or ADJUST is specified in the MONTHLY statement. See the section “[OUTTDR= Data Set](#)” on page 2266 for details.

YRAHEADOUT

adds one-year-ahead forecast values to the output data set for tables C16, C18, and D10. The original purpose of this option was to avoid recomputation of the seasonal adjustment factors when new data became available. While computing costs were an important factor when the X-11 method was developed, this is no longer the case and this option is obsolete. See the section “[The YRAHEADOUT Option](#)” on page 2261 for details.

ARIMA Statement

ARIMA options ;

The ARIMA statement applies the X-11-ARIMA method to the series specified in the VAR statement. This method uses an ARIMA model estimated from the original data to extend the series one or more years. The ARIMA statement options control the ARIMA model used and the estimation, forecasting, and printing of this model.

There are two ways of obtaining an ARIMA model to extend the series. A model can be given explicitly with the MODEL= and TRANSFORM= options. Alternatively, the best-fitting model from a set of five predefined models is found automatically whenever the MODEL= option is absent. See the section “[Details of Model Selection](#)” on page 2262 for details.

BACKCAST= *n*

specifies the number of years to backcast the series. The default is BACKCAST= 0. See the section “[Effect of Backcast and Forecast Length](#)” on page 2261 for details.

CHICR= *value*

specifies the criteria for the significance level for the Box-Ljung chi-square test for lack of fit when testing the five predefined models. The default is CHICR= 0.05. The CHICR= option values must be between 0.01 and 0.90. The hypothesis being tested is that of model adequacy.

Nonrejection of the hypothesis is evidence for an adequate model. Making the CHICR= value smaller makes it easier to accept the model. See the section “[Criteria Details](#)” on page 2263 for further details on the CHICR= option.

CONVERGE= *value*

specifies the convergence criterion for the estimation of an ARIMA model. The default value is 0.001. The CONVERGE= value must be positive.

FORECAST= *n*

specifies the number of years to forecast the series. The default is FORECAST= 1. See the section “[Effect of Backcast and Forecast Length](#)” on page 2261 for details.

MAPECR= *value*

specifies the criteria for the mean absolute percent error (MAPE) when testing the five pre-defined models. A small MAPE value is evidence for an adequate model; a large MAPE value results in the model being rejected. The MAPECR= value is the boundary for acceptance/rejection. Thus a larger MAPECR= value would make it easier for a model to pass the criteria. The default is MAPECR= 15. The MAPECR= option values must be between 1 and 100. See the section “[Criteria Details](#)” on page 2263 for further details on the MAPECR= option.

MAXITER= *n*

specifies the maximum number of iterations in the estimation process. MAXITER must be between 1 and 60; the default value is 15.

METHOD= CLS**METHOD=** ULS**METHOD=** ML

specifies the estimation method. ML requests maximum likelihood, ULS requests unconditional least squares, and CLS requests conditional least squares. METHOD=CLS is the default. The maximum likelihood estimates are more expensive to compute than the conditional least squares estimates. In some cases, however, they can be preferable. For further information on the estimation methods, see “[Estimation Details](#)” on page 252 in Chapter 7, “[The ARIMA Procedure](#).”

MODEL= (**P=***n1* **Q=***n2* **SP=***n3* **SQ=***n4* **DIF=***n5* **SDIF=***n6* < **NOINT** > < **CENTER** >)

specifies the ARIMA model. The AR and MA orders are given by P=*n1* and Q=*n2*, respectively, while the seasonal AR and MA orders are given by SP=*n3* and SQ=*n4*, respectively. The lag corresponding to seasonality is determined by the MONTHLY or QUARTERLY statement. Similarly, differencing and seasonal differencing are given by DIF=*n5* and SDIF=*n6*, respectively.

For example

```
arima model=( p=2 q=1 sp=1 dif=1 sdif=1 );
```

specifies a (2,1,1)(1,1,0)*s* model, where *s*, the seasonality, is either 12 (monthly) or 4 (quarterly). More examples of the MODEL= syntax are given in the section “[Details of Model Selection](#)” on page 2262.

NOINT

suppresses the fitting of a constant (or intercept) parameter in the model. (That is, the parameter μ is omitted.)

CENTER

centers each time series by subtracting its sample mean. The analysis is done on the centered data. Later, when forecasts are generated, the mean is added back. Note that centering is done after differencing. The CENTER option is normally used in conjunction with the NOCONSTANT option of the ESTIMATE statement.

For example, to fit an AR(1) model on the centered data without an intercept, use the following ARIMA statement:

```
arima model=( p=1 center noint );
```

NOPRINT

suppresses the normal printout generated by the ARIMA statement. Note that the effect of specifying the NOPRINT option in the ARIMA statement is different from the effect of specifying the NOPRINT in the PROC X11 statement, since the former only affects ARIMA output.

OVDIFCR= value

specifies the criteria for the over-differencing test when testing the five predefined models. When the MA parameters in one of these models sum to a number close to 1.0, this is an indication of over-parameterization and the model is rejected. The OVDIFCR= value is the boundary for this rejection; values greater than this value fail the over-differencing test. A larger OVDIFCR= value would make it easier for a model to pass the criteria. The default is OVDIFCR= 0.90. The OVDIFCR= option values must be between 0.80 and 0.99. See the section “[Criteria Details](#)” on page 2263 for further details on the OVDIFCR= option.

PRINTALL

provides the same output as the default printing for all models fit and, in addition, prints an estimation summary and chi-square statistics for each model fit. See “[Printed Output](#)” on page 2268 for details.

PRINTFP

prints the results for the initial pass of X11 made to exclude trading-day effects. This option has an effect only when the TDREGR= option specifies ADJUST, TEST, or PRINT. In these cases, an initial pass of the standard X11 method is required to get rid of calendar effects before doing any ARIMA estimation. Usually this first pass is not of interest, and by default no tables are printed. However, specifying PRINTFP in the ARIMA statement causes any tables printed in the final pass to also be printed for this initial pass.

TRANSFORM= (LOG) | LOG**TRANSFORM= (constant ** power)**

The ARIMA statement in PROC X11 allows certain transformations on the series before estimation. The specified transformation is applied only to a user-specified model. If TRANSFORM= is specified and the MODEL= option is not specified, the transformation request is ignored and a warning is printed.

The LOG transformation requests that the natural log of the series be used for estimation. The resulting forecast values are transformed back to the original scale.

A general power transformation of the form $X_t \rightarrow (X_t + a)^b$ is obtained by specifying

```
transform= ( a ** b )
```

If the constant a is not specified, it is assumed to be zero. The specified ARIMA model is then estimated using the transformed series. The resulting forecast values are transformed back to the original scale.

BY Statement

BY *variables* ;

A BY statement can be used with PROC X11 to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input DATA= data set to be sorted in order of the BY variables.

ID Statement

ID *variables* ;

If you are creating an output data set, use the ID statement to put values of the ID variables, in addition to the table values, into the output data set. The ID statement has no effect when an output data set is not created. If the DATE= variable is specified in the MONTHLY or QUARTERLY statement, this variable is included automatically in the OUTPUT data set. If no DATE= variable is specified, the variable _DATE_ is added.

The date variable (or _DATE_) values outside the range of the actual data (from ARIMA forecasting or backcasting, or from YRAHEADOUT) are extrapolated, while all other ID variables are missing.

MACURVES Statement

MACURVES *month=option ...* ;

The MACURVES statement specifies the length of the moving-average curves for estimating the seasonal factors for any month. This statement can be used only with monthly time series data.

The *month=option* specifications consist of the month name (or the first three letters of the month name), an equal sign, and one of the following option values:

'3' specifies a three-term moving average for the month

'3X3'	specifies a three-by-three moving average
'3X5'	specifies a three-by-five moving average
'3X9'	specifies a three-by-nine moving average
STABLE	specifies a stable seasonal factor (average of all values for the month)

For example, the statement

```
macurves jan='3' feb='3x3' march='3x5' april='3x9';
```

uses a three-term moving average to estimate seasonal factors for January, a 3×3 (a three-term moving average of a three-term moving average) for February, a 3×5 (a three-term moving average of a five-term moving average) for March, and a 3×9 (a three-term moving average of a nine-term moving average) for April.

The numeric values used for the weights of the various moving averages and a discussion of the derivation of these weights are given in Shiskin, Young, and Musgrave (1967). A general discussion of moving average weights is given in Dagum (1985).

If the specification for a month is omitted, the X11 procedure uses a three-by-three moving average for the first estimate of each iteration and a three-by-five average for the second estimate.

MONTHLY Statement

MONTHLY options ;

The MONTHLY statement must be used when the input data to PROC X11 are a monthly time series. The MONTHLY statement specifies options that determine the computations performed by PROC X11 and what is included in its output. Either the DATE= or START= option must be used.

The following options can appear in the MONTHLY statement.

ADDITIVE

performs additive adjustments. If the ADDITIVE option is omitted, PROC X11 performs multiplicative adjustments.

CHARTS= STANDARD

CHARTS= FULL

CHARTS= NONE

specifies the charts produced by the procedure. The default is CHARTS=STANDARD, which specifies 12 monthly seasonal charts and a trend cycle chart. If you specify CHARTS=FULL (or CHARTS=ALL), the procedure prints additional charts of irregular and seasonal factors. To print no charts, specify CHARTS=NONE.

The TABLES statement can also be used to specify particular monthly charts to be printed. If no CHARTS= option is given, and a TABLES statement is given, the TABLES statement

overrides the default value of CHARTS=STANDARD; that is, no charts (or tables) are printed except those specified in the TABLES statement. However, if both the CHARTS= option and a TABLES statement are given, the charts corresponding to the CHARTS= option and those requested by the TABLES statement are printed.

For example, suppose you wanted only charts G1, the final seasonally adjusted series and trend cycle, and G4, the final irregular and final modified irregular series. You would specify the following statements:

```
monthly date=date;
tables g1 g4;
```

DATE= *variable*

specifies a variable that gives the date for each observation. The starting and ending dates are obtained from the first and last values of the DATE= variable, which must contain SAS date values. The procedure checks values of the DATE= variable to ensure that the input observations are sequenced correctly. This variable is automatically added to the OUTPUT= data set if one is requested and extrapolated if necessary. If the DATE= option is not specified, the START= option must be specified.

The DATE= option and the START= and END= options can be used in combination to subset a series for processing. For example, suppose you have 12 years of monthly data (144 observations, no missing values) beginning in January 1970 and ending in December 1981, and you wanted to seasonally adjust only six years beginning in January 1974. Specifying

```
monthly date=date start=jan1974 end=dec1979;
```

would seasonally adjust only this subset of the data. If instead you wanted to adjust the last eight years of data, only the START= option is needed:

```
monthly date=date start=jan1974;
```

END= *mmmyyyy*

specifies that only the part of the input series ending with the month and year given be adjusted (for example, END=DEC1970). See the DATE=*variable* option for using the START= and END= options to subset a series for processing.

EXCLUDE= *value*

excludes from the trading-day regression any irregular values that are more than *value* standard deviations from the mean. The EXCLUDE=*value* must be between 0.1 and 9.9, with the default value being 2.5.

FULLWEIGHT= *value*

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values less than the FULLWEIGHT= *value* (in standard deviation units) are assigned full weights of 1, values that fall between the ZEROWEIGHT= and FULLWEIGHT= limits are assigned

weights linearly graduated between 0 and 1, and values greater than the ZEROWEIGHT= limit are assigned a weight of 0.

For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The FULLWEIGHT=value must be between 0.1 and 9.9 but must be less than the ZEROWEIGHT=value. The default is FULLWEIGHT=1.5.

LENGTH

includes length-of-month allowance in computing trading-day factors. If this option is omitted, length-of-month allowances are included with the seasonal factors.

NDEC= *n*

specifies the number of decimal places shown in the printed tables in the listing. This option has no effect on the precision of the variable values in the output data set.

PMFACTOR= *variable*

specifies a variable containing the prior monthly factors. Use this option if you have previous knowledge of monthly adjustment factors. The PMFACTOR= option can be used to make the following adjustments:

- adjust the level of all or part of a series with discontinuities
- adjust for the influence of holidays that fall on different dates from year to year, such as the effect of Easter on certain retail sales
- adjust for unreasonable weather influence on series, such as housing starts
- adjust for changing starting dates of fiscal years (for budget series) or model years (for automobiles)
- adjust for temporary dislocating events, such as strikes

See the section “[Prior Daily Weights and Trading-Day Regression](#)” on page 2259 for details and examples using the PMFACTOR= option.

PRINTOUT= STANDARD | LONG | FULL | NONE

specifies the tables to be printed by the procedure. If the PRINTOUT=STANDARD option is specified, between 17 and 27 tables are printed, depending on the other options that are specified. PRINTOUT=LONG prints between 27 and 39 tables, and PRINTOUT=FULL prints between 44 and 59 tables. Specifying PRINTOUT=NONE results in no tables being printed; however, charts are still printed. The default is PRINTOUT=STANDARD.

The TABLES statement can also be used to specify particular monthly tables to be printed. If no PRINTOUT= option is specified, and a TABLES statement is given, the TABLES statement overrides the default value of PRINTOUT=STANDARD; that is, no tables (or charts) are printed except those given in the TABLES statement. However, if both the PRINTOUT= option and a TABLES statement are specified, the tables corresponding to the PRINTOUT= option and those requested by the TABLES statement are printed.

START= *mmmyyyy*

adjusts only the part of the input series starting with the specified month and year. When the DATE= option is not used, the START= option gives the year and month of the first input

observation — for example, START=JAN1966. START= must be specified if DATE= is not given. If START= is specified (and no DATE= option is given), and an OUT= data set is requested, a variable named _DATE_ is added to the data set, giving the date value for each observation. See the DATE= *variable* option for using the START= and END= options to subset a series.

SUMMARY

specifies that the data are already seasonally adjusted and the procedure is to produce summary measures. If the SUMMARY option is omitted, the X11 procedure performs seasonal adjustment of the input data before calculating summary measures.

TD COMPUTE= *year*

uses the part of the input series beginning with January of the specified year to derive trading-day weights. If this option is omitted, the entire series is used.

TD REGR= NONE | PRINT | ADJUST | TEST

specifies the treatment of trading-day regression. TDREG=NONE omits the computation of the trading-day regression. TDREG=PRINT computes and prints the trading-day regressions but does not adjust the series. TDREG=ADJUST computes and prints the trading-day regression and adjusts the irregular components to obtain preliminary weights. TDREG=TEST adjusts the final series if the trading-day regression estimates explain significant variation on the basis of an F test (or residual trading-day variation if prior weights are used). The default is TDREGR=NONE.

See the section “[Prior Daily Weights and Trading-Day Regression](#)” on page 2259 for details and examples using the TDREGR= option.

If ARIMA processing is requested, any value of TDREGR other than the default TDREGR=NONE will cause PROC X11 to perform an initial pass (see the “[Details: X11 Procedure](#)” on page 2250 section and the PRINTFP option).

The significance level reported in Table C15 should be viewed with caution. The dependent variable in the trading-day regression is the irregular component formed by an averaging operation. This induces a correlation in the dependent variable and hence in the residuals from which the F test is computed. Hence the distribution of the trading-day regression F statistics differs from an exact F ; see Cleveland and Devlin (1980) for details.

TRENDADJ

modifies extreme irregular values prior to computing the trend cycle estimates in the first iteration. If the TRENDADJ option is omitted, the trend cycle is computed without modifications for extremes.

TRENDMA= 9 | 13 | 23

specifies the number of terms in the moving average to be used by the procedure in estimating the variable trend cycle component. The value of the TRENDMA= option must be 9, 13, or 23. If the TRENDMA= option is omitted, the procedure selects an appropriate moving average. For information about the number of terms in the moving average, see Shiskin, Young, and Musgrave (1967).

ZEROWEIGHT= *value*

assigns weights to irregular values based on their distance from the mean in standard deviation

units. The weights are used for estimating seasonal and trend cycle components. Irregular values beyond the standard deviation limit specified in the ZEROWEIGHT= option are assigned zero weights. Values that fall between the two limits (ZEROWEIGHT= and FULLWEIGHT=) are assigned weights linearly graduated between 0 and 1. For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The ZEROWEIGHT= value must be between 0.1 and 9.9 but must be greater than the FULLWEIGHT= value. The default is ZEROWEIGHT=2.5.

The ZEROWEIGHT option can be used in conjunction with the FULLWEIGHT= option to adjust outliers from a monthly or quarterly series. See [Example 33.3](#) later in this chapter for an illustration of this use.

OUTPUT Statement

OUTPUT OUT= *SAS-data-set tablename=var1 var2 ... ;*

The OUTPUT statement creates an output data set containing specified tables. The data set is named by the OUT= option.

OUT= *SAS-data-set*

If OUT= is omitted, the SAS System names the new data set by using the DATA n convention.

For each table to be included in the output data set, write the X11 table identification keyword, an equal sign, and a list of new variable names:

tablename = var1 var2 ...

The *tablename* keywords that can be used in the OUTPUT statement are listed in the section “[Printed Output](#)” on page 2268. The following is an example of a VAR statement and an OUTPUT statement:

```
var z1 z2 z3;
output out=out_x11 b1=s d11=w x y;
```

The variable s contains the table B1 values for the variable z1, while the table D11 values for variables z1, z2, and z3 are contained in variables w, x, and y, respectively. As this example shows, the list of variables following a *tablename=* keyword can be shorter than the VAR variable list.

In addition to the variables named by *tablename =var1 var2 ...*, the ID variables, and BY variables, the output data set contains a date identifier variable. If the DATE= option is given in the MONTHLY or QUARTERLY statement, the DATE= variable is the date identifier. If no DATE= option is given, a variable named `_DATE_` is the date identifier.

PDWEIGHTS Statement

PDWEIGHTS *day=w ... ;*

The PDWEIGHTS statement can be used to specify one to seven daily weights. The statement can only be used with monthly series that are seasonally adjusted using the multiplicative model. These weights are used to compute prior trading-day factors, which are then used to adjust the original series prior to the seasonal adjustment process. Only relative weights are needed; the X11 procedure adjusts the weights so that they sum to 7.0. The weights can also be corrected by the procedure on the basis of estimates of trading-day variation from the input data.

See the section “Prior Daily Weights and Trading-Day Regression” on page 2259 for details and examples using the PDWEIGHTS statement.

Each *day=w* option specifies a weight (*w*) for the named day. The *day* can be any day, Sunday through Saturday. The *day* keyword can be the full spelling of the day, or the three-letter abbreviation. For example, SATURDAY=1.0 and SAT=1.0 are both valid. The weights *w* must be a numeric value between 0.0 and 10.0.

The following is an example of a PDWEIGHTS statement:

```
pdweights sun=.2 mon=.9 tue=1 wed=1 thu=1 fri=.8 sat=.3;
```

Any number of days can be specified with one PDWEIGHTS statement. The default weight value for any day that is not specified is 0. If you do not use a PDWEIGHTS statement, the program computes daily weights if TDREGR=ADJUST is specified. See Shiskin, Young, and Musgrave (1967) for details.

QUARTERLY Statement

QUARTERLY *options ;*

The QUARTERLY statement must be used when the input data are quarterly time series. This statement includes options that determine the computations performed by the procedure and what is in the printed output. The DATE= option or the START= option must be used.

The following options can appear in the QUARTERLY statement.

ADDITIVE

performs additive adjustments. If this option is omitted, the procedure performs multiplicative adjustments.

CHARTS= STANDARD

CHARTS= FULL

CHARTS= NONE

specifies the charts to be produced by the procedure. The default value is

CHARTS=STANDARD, which specifies four quarterly seasonal charts and a trend cycle chart. If you specify CHARTS=FULL (or CHARTS=ALL), the procedure prints additional charts of irregular and seasonal factors. To print no charts, specify CHARTS=NONE. The TABLES statement can also be used to specify particular charts to be printed. The presence of a TABLES statement overrides the default value of CHARTS=STANDARD; that is, if a TABLES statement is specified, and no CHARTS=option is specified, no charts (nor tables) are printed except those given in the TABLES statement. However, if both the CHARTS=option and a TABLES statement are given, the charts corresponding to the CHARTS=option and those requested by the TABLES statement are printed.

For example, suppose you wanted only charts G1, the final seasonally adjusted series and trend cycle, and G4, the final irregular and final modified irregular series. This is accomplished by specifying the following statements:

```
quarterly date=date;
tables g1 g4;
```

DATE= *variable*

specifies a variable that gives the date for each observation. The starting and ending dates are obtained from the first and last values of the DATE= variable, which must contain SAS date values. The procedure checks values of the DATE= variable to ensure that the input observations are sequenced correctly. This variable is automatically added to the OUTPUT= data set if one is requested, and extrapolated if necessary. If the DATE= option is not specified, the START= option must be specified.

The DATE= option and the START= and END= options can be used in combination to subset a series for processing. For example, suppose you have a series with 10 years of quarterly data (40 observations, no missing values) beginning in '1970Q1' and ending in '1979Q4', and you want to seasonally adjust only four years beginning in '1974Q1' and ending in '1977Q4'. Specifying

```
quarterly date=variable start='1974q1' end='1977q4';
```

seasonally adjusts only this subset of the data. If instead you wanted to adjust the last six years of data, only the START= option is needed:

```
quarterly date=variable start='1974q1';
```

END= 'yyyyQq'

specifies that only the part of the input series ending with the quarter and year given be adjusted (for example, END='1973Q4'). The specification must be enclosed in quotes and *q* must be 1, 2, 3, or 4. See the DATE= *variable* option for using the START= and END= options to subset a series.

FULLWEIGHT= *value*

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values less than the FULLWEIGHT= value (in standard deviation units) are assigned full weights

of 1, values that fall between the ZEROWEIGHT= and FULLWEIGHT= limits are assigned weights linearly graduated between 0 and 1, and values greater than the ZEROWEIGHT= limit are assigned a weight of 0.

For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The default is FULLWEIGHT=1.5.

NDEC= *n*

specifies the number of decimal places shown on the output tables. This option has no effect on the precision of the variables in the output data set.

PRINTOUT= STANDARD

PRINTOUT= LONG

PRINTOUT= FULL

PRINTOUT= NONE

specifies the tables to print. If PRINTOUT=STANDARD is specified, between 17 and 27 tables are printed, depending on the other options that are specified. PRINTOUT=LONG prints between 27 and 39 tables, and PRINTOUT=FULL prints between 44 and 59 tables. Specifying PRINTOUT=NONE results in no tables being printed. The default is PRINTOUT=STANDARD.

The TABLES statement can also specify particular quarterly tables to be printed. If no PRINTOUT= is given, and a TABLES statement is given, the TABLES statement overrides the default value of PRINTOUT=STANDARD; that is, no tables (or charts) are printed except those given in the TABLES statement. However, if both the PRINTOUT= option and a TABLES statement are given, the tables corresponding to the PRINTOUT= option and those requested by the TABLES statement are printed.

START= 'yyyyQq'

adjusts only the part of the input series starting with the quarter and year given. When the DATE= option is not used, the START= option gives the year and quarter of the first input observation (for example, START='1967Q1'). The specification must be enclosed in quotes, and *q* must be 1, 2, 3, or 4. START= must be specified if the DATE= option is not given. If START= is specified (and no DATE= is given), and an OUTPUT= data set is requested, a variable named _DATE_ is added to the data set, giving the date value for a given observation. See the DATE= option for using the START= and END= options to subset a series.

SUMMARY

specifies that the input is already seasonally adjusted and that the procedure is to produce summary measures. If this option is omitted, the procedure performs seasonal adjustment of the input data before calculating summary measures.

TRENDADJ

modifies extreme irregular values prior to computing the trend cycle estimates. If this option is omitted, the trend cycle is computed without modification for extremes.

ZEROWEIGHT= *value*

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular

values beyond the standard deviation limit specified in the ZEROWEIGHT= option are assigned zero weights. Values that fall between the two limits (ZEROWEIGHT= and FULLWEIGHT=) are assigned weights linearly graduated between 0 and 1. For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The default is ZEROWEIGHT=2.5.

The ZEROWEIGHT option can be used in conjunction with the FULLWEIGHT= option to adjust outliers from a monthly or quarterly series. See [Example 33.3](#) later in this chapter for an illustration of this use.

SSPAN Statement

SSPAN options ;

The SSPAN statement applies sliding spans analysis to determine the suitability of seasonal adjustment for an economic series.

The following options can appear in the SSPAN statement:

NDEC= *n*

specifies the number of decimal places shown on selected sliding span reports. This option has no effect on the precision of the variables values in the OUTSPAN output data set.

CUTOFF= *value*

gives the percentage value for determining an excessive difference within a span for the seasonal factors, the seasonally adjusted series, and month-to-month and year-to-year differences in the seasonally adjusted series. The default value is 3.0. The use of the CUTOFF=*value* in determining the maximum percent difference (MPD) is described in the section “[Computational Details for Sliding Spans Analysis](#)” on page 2256. Caution should be used in changing the default CUTOFF=*value*. The empirical threshold ranges found by the U.S. Census Bureau no longer apply when value is changed.

TDCUTOFF= *value*

gives the percentage value for determining an excessive difference within a span for the trading-day factors. The default value is 2.0. The use of the TDCUTOFF=*value* in determining the maximum percent difference (MPD) is described in the section “[Computational Details for Sliding Spans Analysis](#)” on page 2256. Caution should be used in changing the default TDCUTOFF=*value*. The empirical threshold ranges found by the U.S. Census Bureau no longer apply when the value is changed.

NOPRINT

suppresses all sliding span reports. See “[Computational Details for Sliding Spans Analysis](#)” on page 2256 for more details on sliding span reports.

PRINT

prints the summary sliding span reports S 0 through S 6.E.

PRINTALL

prints the summary sliding spans report S 0 through S 6.E, along with detail reports S 7.A through S 7.E.

TABLES Statement

TABLES *tablename* ;

The TABLES statement prints the tables specified in addition to the tables that are printed as a result of the PRINTOUT= option in the MONTHLY or QUARTERLY statement. Table names are listed in Table 33.4 later in this chapter.

To print only selected tables, omit the PRINTOUT= option in the MONTHLY or QUARTERLY statement and list the tables to be printed in the TABLES statement. For example, to print only the final seasonal factors and final seasonally adjusted series, use the statement

```
tables d10 d11;
```

VAR Statement

VAR *variables* ;

The VAR statement is used to specify the variables in the input data set that are to be analyzed by the procedure. Only numeric variables can be specified. If the VAR statement is omitted, all numeric variables are analyzed except those appearing in a BY or ID statement or the variable named in the DATE= option in the MONTHLY or QUARTERLY statement.

Details: X11 Procedure

Historical Development of X-11

This section briefly describes the historical development of the standard X-11 seasonal adjustment method and the later development of the X-11-ARIMA method. Most of the following discussion is based on a comprehensive article by Bell and Hillmer (1984), which describes the history of X-11 and the justification of using seasonal adjustment methods, such as X-11, given the current availability of time series software. For further discussions about statistical problems associated with the X-11 method, see Ghysels (1990).

Seasonal adjustment methods began to be developed in the 1920s and 1930s, before there were suitable analytic models available and before electronic computing devices were in existence. The lack of any suitable model led to methods that worked the same for any series — that is, methods that were not model-based and that could be applied to any series. Experience with economic series had shown that a given mathematical form could adequately represent a time series only for a fixed length; as more data were added, the model became inadequate. This suggested an approach that used moving averages. For further analysis of the properties of X-11 moving averages, see Cleveland and Tiao (1976).

The basic method was to break up an economic time series into long-term trend, long-term cyclical movements, seasonal movements, and irregular fluctuations.

Early investigators found that it was not possible to uniquely decompose the trend and cycle components. Thus, these two were grouped together; the resulting component is usually referred to as the “trend cycle component.”
